The method of the game is now so well known that only a brief description is necessary. There are eleven players on each side, and two batsmen are at the wicket, and to get them out is the object of eleven opponents, two of whom are bowling, one at each end, and the other nine fielding. For all practical purposes there are five ways of getting the batsman out; though there are others, which seldom occur—such as hitting the wicket with the bat, obstructing the field, hitting the ball twice and starting to run, &c. The first stage is the bowler delivering the ball at a wicket which is defended by a batsman. If the ball hits the wicket so as to dislodge a bail the batsman is bowled out (No. 1). If the batsman hits the ball, and it is caught by any of the fieldsmen or the bowler before it touches the ground, the batsman is caught out (No. 2). If the ball is not hit, but taken by the wicket-keeper, who stands close behind the stumps, and the wicket is broken when the batsman is outside the popping-crease—a straight line 4 feet distant from, and parallel with, the wicket—the batsman is stumped (No. 3). If the batsman hits the ball and with his colleague at the other end runs, and either wicket is knocked down or put down before the batsman who is running towards that wicket has got his bat grounded or one of his feet over the popping-crease, the batsman is run out (No. 4). If the ball is not hit, but hits the batsman on the leg, and, in the opinion of the umpire, was pitched between wicket and wicket and would have hit the wicket if it had not been interfered with, the batsman is out l.b.w. (No. 5). Runs are made not only from the bat; they come from wides (balls which in the opinion of the umpire are outwith the batsman's reach), no-balls (balls jerked or thrown, or delivered while the bowler's foot is beyond the bowling-crease), byes (obtained by the batsmen running after the ball bowled has passed the wicket), and leg-byes (obtained by the batsmen running when the ball has struck some part of the batsman's body).

The object of each side is to get more runs than its opponents, and in one, two, or three day matches each eleven bats twice; but it frequently happens that one side is so superior to the other that it can win the match batting once to the other's twice. If a side leads by 150 runs in a three-day match, or by 100 runs in a two-day match, or 75 runs in a one-day match, it has the option of compelling the other side to go in again. In old days there was no option; there was a compulsory follow on when a side was 80 (afterwards 120) runs behind. If one side following on cannot equal the number of runs got by the other in its first and only innings, it is beaten in one innings, a fate that makes the iron enter into the soul of a keen captain.

Some few years ago the very easy wickets caused one of the minor developments of the game. Now the ball never shoots—that is, keeps close to the ground after pitching—and batsmen of the first class have become so numerous that it is almost impossible for them to be bowled out. Bowlers try and get them caught, and the practice has now

developed into a system, of bowling wide at the wicket on the off side to tempt batsmen to hit at the ball and get caught. Batsmen did not run the risk, and refused to fall into the trap by simply leaving the ball alone, and the game became slow and dull. To a great extent this is the case still, but it is not so noticeable, as the public became weary of it, and the expense of the game is so great that gate-money is essential. But whereas in old days the bowler had but one object before him, which was to bowl the batsman out, he has now another, which is to get the batsman caught, and to do this balls off the wicket are more efficacious than if they were straight. It often happens, however, that a first-class batsman gets so firmly set that he is impervious, especially on a wicket that is not of the fastest, which may be called a half-stump wicket, as the ball never rises more than half the stump high. But human nature being what it is, a batsman sometimes gets himself out by committing, perhaps, one act of indiscretion; he lashes furiously at an off-ball, or rushes out to a slow without gauging its length, but he is out because he has been indiscreet, and not because the bowler has beaten him. If it were not for these occasional lapses few three-day matches on fast wickets would be finished.

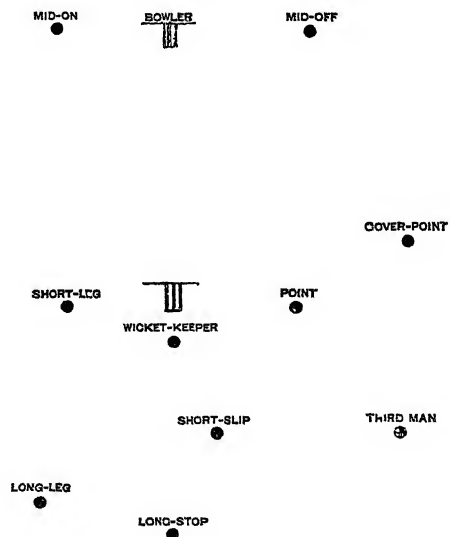

This large run-getting is never seen in a wet summer like 1910. There must always be many drawn matches in England, because rain prevents play, but matches are frequently finished in a rainy season in two days because slower-paced bowlers are helped by the softer pitches. The batsman has something to do; the bowler can make the ball bite the ground and turn or hang—i.e. stop and come on at a different pace—and a real duel is seen on more or less equal terms between bowler and batsman. It was a well-known fact that there were more keen, exciting matches with close finishes in 1910 than in any other year during the thirty years previous to 1912. It is absolutely true to say that there is nothing in any game to compare with a close finish in a cricket match. The excitement is not over in a short time—it frequently lasts the whole day; and it is safe to say that no situation is more trying to the nerves than that of a batsman who has to bat when every run or minute that he stays at the wicket is of importance in a match such as the test, university, or public school matches; and this is the charm of cricket. Perhaps the five best examples of such a match were the test matches at the Oval and Manchester in 1882 and 1902, the university matches of 1870 and 1875, and the Eton and Harrow match of 1910.

International cricket is now confined to the matches between England, Australia, and South Africa, of which the most important are those between England and Australia; but whereas those in this country have been limited to three days, and very frequently drawn, those in Australia and Africa are played to a finish. Apart from international cricket, the annual matches between Gentlemen and Players and that between Oxford and Cambridge Universities attract the most interest; but the backbone of English cricket is county cricket, which in the populous counties excites great interest.

It is impossible to do more than glance at the list of great players. W. G. Grace stands supreme as the greatest cricketer that ever lived. In his absolute prime, between 1868 and 1876, as a batsman he stood in a class by himself, and was a very successful bowler as well. Shrewsbury, on tricky, soft wickets, was perhaps even more difficult to get out; and other batting giants since 1870 have been Stoddart, A. G. Steel, A. P. Lucas, Gunn, W. Barnes, Ranjitsinhji, Jackson (a great player when his side was in a tight place), R. E. Foster,

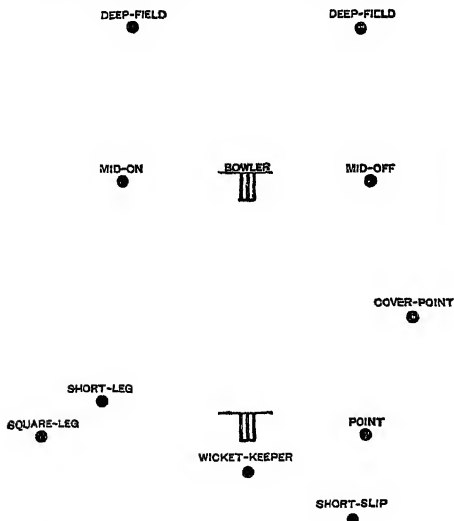

Fry, Maclaren (especially in Australia), Hayward, Hobbs, Sutcliffe, and others. Among faster bowlers, Richardson and Lockwood stand alone, and Alfred Shaw, Peate, Biggs, A. G. Steel, Lohmann, Hirst, and Blythe among the slower. England has always been rich in all-round cricketers—W. G. Grace, A. G. Steel, Jackson, Peel, Hirst, Rhodes, and Braund being as great as any. The Australians have specialised more; their cricketers do not as a rule shine conspicuously both as batsmen and bowlers, except Giffen, Noble, Armstrong, and J. M. Gregory; though Giffen's merits as a batsman have been overestimated. On the other hand, very few of the Australian bowlers are really useless as batsmen; on the contrary, they are often seen to play most doggedly at a pinch. The greatest Australian bats have been C. Bannerman, Murdoch, Scott, McDonnell, Darling, Trumper, Gregory, Bardsley, Duff, and Macartney, and none of these could be called bowlers, but they were all splendid batsmen. Their greatest bowlers have been Spofforth, Palmer, Turner, Trumble, and Macdonald. On the Australian wicket Palmer and Turner were perhaps the best; but in England Spofforth's claim to be the finest bowler the world has ever seen would be agreed to by most judges of the game. South Africa is a new arrival, but in G. A. Faulkner it has produced one of the greatest all-round cricketers that have ever been seen; but its bowlers have mainly been of the slow googly type, in which they have excelled.

The positions taken by the fieldsmen depend not only on the style of bowling, but the style of batsman as well. A hard cutter like Tarrant playing fast bowling on a fast wicket may want a second third man standing deep against the ropes to save 'fours,' and a strong player off his legs often finds himself confronted with two short-legs. In old days the placing of the field to fast bowling was very seldom varied, and was as under:

If a batsman especially strong as a square-leg hitter, like the late Mr R. A. H. Mitchell, were batting, long-leg would be moved to a position near the ropes in a line with the wicket; and to a cutter like the present Lord Cobham, nearly fifty years ago, third man would be moved back against the ropes, mid-on put third man, and short-leg would stand nearer the bowler, and become a hybrid mid-on. But as a general rule the above diagram shows the positions of the fieldsmen to fast bowlers.

To slow bowling the field was as follows :

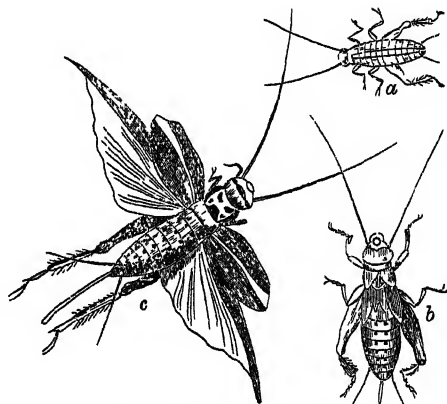

This was the position of the field to slow bowling and to the normal batsman. Many batsmen, however, could not hit hard in front of them, so one of the outfields was brought in and became perhaps a third man or a fine short-leg.

In the present day it may be said there is no fixed principle of placing the field, and the first change was the complete abolition of long-stop. The great Australian wicket-keeper, Blackham, in 1878 showed that this could be done on true grounds and to accurate bowling; and after he retired the practice became universal of standing back to fast bowling. The abolition of long-stop enables the captain to put an extra man in the slips or between mid-off and cover-point. The appearance of the googly bowler—i.e. the bowler who breaks both ways—and the bowler with a swerve has revolutionised the placing of the field. Frequently, to googly bowlers, there is no fieldsman in the slips at all, and no point, but cover-point stands more like a deep-point. There are two deep-fields, and one short-leg square with the wicket and another very fine. To very fast bowlers, such as the late Tom Richardson and Mr Jones, the Australian, the wicket-keeper stands back, and there are four slips; and George Hirst, when bowling his swerve, has three short-legs, two behind the wicket and one square.

See Nyren's *Young Cricketers' Tutor* (1833, 1893, 1902); Egan's *Book of Sport*; Wm. Caffyn's *Seventy-one Not Out* (1900); R. Daff's *Kings of Cricket* (1893); *The Jubilee Book of Cricket*, by Prince Ranjitsinhji (1897, 1901); *Cricket*, by W. G. Grace (1891); *How We Recovered the Ashes*, by P. F. Warner (1904); *The Badminton Manual* (1889; 7th ed. by Steel and Lyttelton, 1904; new ed. by P. F. Warner, 1920).

**Cricket** (*Gryllus*), a genus of orthopterous insects akin to grasshoppers. Long feelers, a rasping organ on the wing-covers of the males, wings closely folded lengthwise, but often along with the wing-covers degenerate, great powers of leaping, and a retiring, more or less subterranean habit of life, are some of the more important characteristics of the family (Gryllidae) of which the cricket is a type. The females are fertilised by means of peculiar spermatophores, and as in allied Orthoptera there is no marked metamorphosis in the life-history. In the genus *Gryllus* the head is blunt, the antennae are long and thin, the wings are always present, the hind-legs are very broad and

strong, and the females have a straight protruding egg-laying organ.—The Field Cricket (*G. campestris*) is very common throughout Europe in fields and meadows (local in England), and is very well known from the sound, by means of which the male captivates his mate. The body is compressed, the head is black and shining, the wing-covers are brown and yellow at the roots. As in other crickets, the noise of the males is made by rubbing the wing-covers against one another. The under side of one of the nervures bears over a hundred sharp transverse ridges or teeth. These insects hide in burrows in the ground, and sometimes do much damage to vegetables. The female lays numerous eggs in the burrow, and the larvæ remain as such through the winter.—The House Cricket (*G. domesticus*) has a lank, yellowish-brown body an inch long. A recent arrival in the United States, it is common throughout Europe in houses, is said to occur in the open air in Madeira, and even in Britain occasionally wanders out of doors in summer. It hides in nooks and crevices, and loves the neighbourhood of the fire, especially in winter. Its merry note has become associated with ideas of domesticity (as in Dickens's *Cricket on the Hearth*).

House Cricket (*Gryllus domesticus*):  
a, full-grown larva; b, pupa; c, perfect insect.

Without the heat of the fire, it becomes more or less dormant in winter. It remains quiet during the day, but hunts about actively at night

Mole Cricket and eggs (*Gryllotalpa vulgaris*).

for crumbs and other scraps both animal and vegetable. For the sake of both food and warmth it often frequents bakehouses. The larvæ are wingless, and the pupæ have only rudimentary wings. The loudest noise made by a cricket is probably that of a Sicilian species (*G. megal-*

*cephalus*), which is said to make itself heard 'at a distance of a mile.' Closely allied to the above genus is *Myrmecophila*, a wingless cricket with extremely strong hind-legs. Only the females are known, and these live parasitically in ants' nests. The Mole Cricket (*Gryllotalpa*) belongs to the same family, and is distinguished by the enormous burrowing fore-legs, by the large size of the anterior ring of the thorax, and by the absence of an ovipositor in the females. The only European species (*G. vulgaris*) is a large and formidable insect, sometimes attaining a length of two inches. It is of a grayish-brown colour, with a silken sheen. It burrows like a mole in fields and meadows, but is sometimes seen in flight in the evenings. Numerous eggs, inclosed in a cocoon, are laid underground. The larvæ are long in becoming adult. The mole cricket often does damage by biting at the roots of vegetable crops. Like the field cricket, however, it feeds very largely on ground insects and the like. A South American and West Indian species (*G. didactyla*) damages the sugar-canes.

**Cricklade**, a town in Wiltshire, on the Isis or Thames, 7 miles NNW. of Swindon. Enfranchised under Edward I., it returned two members to parliament till its disfranchisement in 1885, the 'borough' since 1782 having included forty-four parishes and parts of six. Cricklade with Wootton-Bassett now forms a rural district; pop. 11,000.

**Crieff**, a town of Perthshire, on the Earn's left bank, 26 miles NNE. of Stirling, and 18 W. of Perth by two branch-lines opened in 1856-66. It is situated in the midst of exquisite scenery, enjoys a pure dry climate, has a large hydropathic (1867), two old market-crosses, some handsome new churches, and Morrison's Academy (1859). Its famous cattle fair was transferred about 1770 to Falkirk; the manufacture of woollens was introduced in 1812. Of many seats in the neighbourhood, Drummond Castle (1491), Lord Ancaster's, is famous for the formal magnificence of its gardens. Pop. 6000.

**Crillon**, LOUIS DES BALBES DE BERTON DE, surnamed 'Le Brave,' was born at Murs in Provence in 1541. Under Francis of Lorraine, Duke of Guise, then the model of military chivalry, he was trained for war, and, still a boy, covered himself with glory at the siege of Calais, and at the capture of Guines. His heroism was rewarded with a number of church benefices, which he intrusted to the care of learned clerks. He distinguished himself further at Dreux, Jarnac, and Moncontour. Wounded at Lepanto (1571), he was yet sent to carry the news of the victory to the pope and the French king. His noble heart abhorred the treachery and horrors of St Bartholomew, but he took part in the siege of La Rochelle in 1573. Faithful to his king in his struggle with the Catholic League, after his death he gave hearty allegiance to Henry IV. When the peace with Savoy was concluded, Crillon retired to Avignon, and, after the fashion of a true Catholic warrior, ended his days 'in the exercise of piety and penance,' December 2, 1615. A somewhat melodramatic story is told how once when listening at church to an account of the crucifixion, the old hero, brandishing his sword, cried out: 'Where wert thou, Crillon?'

**Crime**, in its legal, as opposed to its moral or ethical sense, is an act done in violation of those duties for the breach of which the law has provided that the offender, in addition to repairing, if it be possible, the injury done to the individual, shall make satisfaction to the community. A private wrong, or civil injury, on the other hand, is an infringement on the rights of an individual merely, for which compensation to him is held to be suffi-

cient. Legal criminality is not a permanent characteristic of actions as such, but one decided by considerations of expediency. Without changing its absolute moral character, the same action may, and very often is, criminal in one country or generation, and no crime in another country or generation. It cannot, however, be supposed that the criminality or non-criminality of an action does not exercise an important reflex influence on the moral judgment of the community with respect to the particular action. Malice or evil intention is essential to the character of most crimes, for though there may be an immoral act which it is inexpedient to punish, it can rarely be expedient to punish what is not an immoral act. But it is not necessary that the evil intention shall be an intention to commit the particular crime which was in fact committed. There is sufficient *mens rea* to found criminal liability, if the offender had an intention to do any act which is either criminal or simply illegal without being criminal. Certain statutory offences may be committed though there is on the part of the offender no guilty knowledge or intention; e.g. the possession of unsound meat for sale, or the sale of an adulterated article of food, is a criminal offence, though the offender did not know the meat to be unsound or the article to be adulterated. The law can take no cognisance of a bare intention which has not ripened into any sort of act. How far Attempts (q.v.) are punishable is always a question of difficulty. The general rule seems to be that if such acts can be unequivocally connected with the criminal intention, they are punishable, though not to the same extent as the completed crime—e.g. if the act is one of a series which, if not interrupted, would result in the commission of the crime, even though the accused voluntarily desisted from further attempts. Pupils under seven years of age, and insane persons, as being incapable of design or intention, are regarded in the eye of the law as incapable of crime; as regards children between seven and fourteen it must be shown that they had capacity to know their act was wrong. In the case of persons under sixteen, otherwise known as juvenile offenders, magistrates have a large discretion to substitute for ordinary punishment confinement in a reformatory school. The legal definition of insanity is well settled in England and Scotland, but is totally inadequate from the medico-psychological point of view. The law of responsibility in drunkenness and *delirium tremens* also requires amendment. Ignorance of law is no defence—e.g. a foreigner, killing his opponent in a duel in England, is guilty of murder. In some cases ignorance of fact is important—e.g. where bigamy is charged against a woman who had reason to believe her husband dead. The defence of *compulsion*, if completely established in fact, is generally sufficient in law. The subjection of a servant to a master, or of a child to a parent, will be no defence. In England, a wife who commits an ordinary crime in her husband's presence and by his instructions is *prima facie* presumed to have committed it under such compulsion as to entitle her to be acquitted; but this rule does not extend to murder or treason, or to any crime committed by her outwith the actual presence of her husband.

In England criminal offences are distinguished as 'indictable'—i.e. those which admit of trial by jury on an indictment—and 'non-indictable'—i.e. those which are tried summarily without a jury. Originally these two groups were exclusive of each other; but, under modern statutes, they now overlap to some extent. Again, crimes are divided into *Misdemeanours* (q.v.) and *Felonies* (q.v.), the latter being a higher species of offence than the former. The Criminal and Judicial Statistics give

annual data as to the number of trials and convictions, and as to prisons and prisoners. See CRIMINAL LAW.

**Crime'a** (Tatar Krym, anciently the Tauric Chersonese), a peninsula of south Russia between the Black Sea and Sea of Azov, joined to the continent of Russia by the Isthmus of Perekop, 18½ miles long by 5½ miles broad at its narrowest part, was formed by the Moscow government in October 1921 into a republic in federal union with Russia. The peninsula is about 200 miles from east to west, by 125 miles from north to south, with about 625 miles of coast-line, and an area of about 15,000 sq. m. In shape it is an irregular quadrilateral, projecting eastwards into the peninsula of Kertch, which terminates at the Strait of Yenikalé. Along the Siwash or Putrid Sea on the north, and the Sea of Azov, the coasts are flat and open. To the west of the wide bay of Kaffa or Theodosia the south coast becomes rocky and elevated, and forms a succession of capes and small gulfs. Balaklava, and more especially Sebastopol, have fine harbours.

In the character of its surface, the north, and much the larger part of the Crimea, is only a continuation of the South Russian steppe. The southern part, from Cape Chersonese to the Strait of Yenikalé, only about one-fifth of the whole peninsula, is highland, traversed by a mountain-chain, the continuation of the Caucasus—a region geologically, climatically, and botanically distinct from the rest of Russia. The limestone mountains from Cape Chersonese to Baffa Bay show deep erosion, presenting the ruins of a vast tableland, sloping gently northwards into the steppe, but hanging in abrupt precipices southwards. Chatîr Dag or Tent Mount (anciently Mons Trapezus or Table Mount), 5450 feet, is a quadrilateral mass of over 8 sq. m., isolated on all sides, and seems to be exceeded in height by Roman Kosh. In the hilly district about Kertch are thermal and naphtha springs, and mud volcanoes. There are some fifty small rivers and rivulets, all fordable except after the melting of the snows and heavy rains. There are about four hundred salt lakes, rich in salt. The climate is healthy, and generally mild. But in winter the steppe is exposed to cold winds, frost, and snowstorms, while the south coast is sheltered and warm. The steppe, though not fertile, yet grazes innumerable herds of cattle, and yields porphyries and various coloured marbles. The northern mountain-slopes are laid out in pastures, thickets, orchards, and gardens watered from the rivers. In the uplands are still magnificent forests of oak, beech, elm, ash, willow, &c. On the southern slopes grow sea-pine; lower down is an Italian vegetation of laurel, pomegranate, fig, arbutus, and vine. Here are famous health-resorts, with Livadia and other former imperial residences. Good wine is largely produced, and some exported. Though the Crimea was once famous for its coin, it has suffered much from drought, and much good land is now uncultivated. The fauna is not rich. Of wild quadrupeds are the hare, fox, and small rodents. All the domestic animals of the steppe have been introduced, as also the two-humped camel. The Crimea has a highly prized oyster. The limestone mountains contain porphyry, diorites, and greenstone. Good coal is mined.

The population numbers about 760,000, of whom the greater part are Tatars, with a quarter of a million Russians, besides Greeks, Jews, Bulgarians, Germans, &c. The capital is Simferopol (q.v.), the old Tartar capital being Bakhiserai (q.v.). The Crimea is connected by railway with the mainland, the lines running to Sebastopol and to Theodosia and Kertch. It has from earliest times been a bone of contention for successive nations, and the

double or more manifold names of many places, Greek, Tatar, Turk, Russian, record the dominations they have successively undergone. For the early history of the Crimea, see BOSPORUS (*Cimmerian Bosphorus*). In the 13th century came the Tatars, the last of the Ghirei dynasty abdicating in favour of Russia, 1787. The Crimea formed part of the republic of Taurida (1918), and in 1920 saw the collapse of Denikin's adventure, and of Wrangel's.

**Crimean War.** For close upon forty years Britain had been at peace with all the great powers of Europe, but in 1853 a war-cloud arose on the eastern horizon. Russia had long cast a covetous eye upon Constantinople and the Sultan's possessions, and had contrived in various treaties to lay the foundation of a claim to something like a protectorate over the Christians of the Greek Church in Turkey, amounting to three-fourths of the Sultan's subjects in Europe. As early as 1844 the Emperor Nicholas had proposed to divide with Britain the inheritance of the 'sick man,' so he called Turkey; and in 1853 he began to urge his claims in a form which Turkey could not accept without ceasing to remain an independent state. The other great powers intervened as mediators, but in vain; and meanwhile a Russian army took possession of Moldavia and Wallachia. After nearly a year of fruitless diplomacy, negotiations were broken off, and Britain and France agreed to support Turkey by armed intervention. War was proclaimed against Russia on 28th March 1854.

The war thus undertaken lasted two years. At first, England and France stood alone in their support of Turkey; but early in 1855 Sardinia boldly joined the alliance, and sent a contingent to the seat of war. The other powers remained neutral throughout the contest. The chief scenes of operation were the Black Sea and the Baltic. In the spring of 1854 a powerful British and French fleet appeared in the Gulf of Finland; but the Russian fleet declined the combat, and kept safe behind the granite fortresses of Cronstadt and Sveaborg, which, owing to shallow water and difficult navigation, could not be attacked by the large vessels composing the allied fleets. The only thing of importance effected, besides imprisoning the enemy's navy and ruining his commerce, was the destruction of the fortress of Bomarsund, and the capture of the Åland Islands, on which it was situated. The second Baltic campaign, in 1855, was a repetition of the first. Sveaborg was bombarded and partially destroyed, but again the want of gun-boats confined the real services of the fleet to a strict blockade of the Russian coasts.

In the Black Sea the Russian fleet followed the same tactics as in the Baltic, and took refuge in the fortified harbour of Sebastopol, sinking vessels across the entrance to keep out the enemy. On land, the Turkish forces, under Omar Pasha, had sustained during the winter of 1853-54 an heroic contest on the Danube against the Russian invaders. The French and British troops sent to the aid of the Sultan were landed at first in European Turkey, chiefly at Varna (April and May 1854). But the valiant defence of Silistria by the Turks themselves rendered our advance in that direction unnecessary; after using every effort for six weeks, the Russians had to retire baffled from before the place. The allies having suffered great loss from cholera at Varna, it was resolved to carry the war into the Crimea; and on 14th September an army of 25,000 British under Lord Raglan, as many French under Marshal St Arnaud, and 8000 Turks, landed on the west coast, 30 miles north of Sebastopol. On the 20th they attacked and completely defeated a Russian army strongly posted on the steep heights above the river Alma; then taking

up position near Balaklava, to the south of Sebastopol, they commenced the siege of that vast fortress. The Russians made repeated attempts, with overwhelming masses of troops, to force the allied position, which led to the sanguinary battles of Balaklava (25th October) and Inkermann (5th November).

Balaklava was mainly a cavalry action, and did far more credit to our soldiers' gallantry than to their commanders' generalship. It will ever be memorable for the glorious charge of the Light Brigade, who, in obedience to a bungled order, rode a mile and a half beneath a murderous fire against the Russian army in position. Faster and faster grew the pace, until with a cheer that was many a hero's death-cry, they broke right into the battery, sabred the gunners, and burst through a column of infantry. Then they paused, and cut their way back; but out of the six hundred who had ridden forth, not two hundred returned. 'It is magnificent, but it is not war,' was the comment of a French general. Inkermann, known as the Soldiers' Battle, was fought on a dark and drizzly morning of autumn. Taken unawares, and short of cartridges, 8000 British sustained for several hours a hand-to-hand fight against six times that number of Russians, till 6000 French came to their aid, and completed the rout of the enemy.

Throughout the ensuing winter, the allies, especially the British, suffered terrible hardships, owing partly to the rigour of the climate, but more to the shameful breakdown of the system for provisioning the army. The supplies of food, clothing, and other necessities were often sent where they were not wanted. The hospitals, too, were frightfully mismanaged; barely 12 per cent. of our total loss in the war (20,656) dying in battle, the rest in hospital. To Florence Nightingale, a lady of gentle birth, was due the establishment of proper nursing in the military hospitals, not merely then, but thereafter.

The prodigious extent and strength of the fortifications of Sebastopol (q.v.), together with the skill and obstinacy of its defence, protracted the siege for nearly a twelvemonth, and rendered it well-nigh the greatest in history. In March 1855 died the Czar Nicholas, whose ambition was the cause of the contest; but under his son and successor, Alexander II., Russia continued to sustain the enormous drain on her population and resources. The trenches, or lines of attack, had drawn closer and closer to the Russian works, till at one point the foes were well within speaking distance; at last, on 8th September 1855, after a three days' tremendous cannonade by the allies, the French stormed and carried the Malakoff fort, the key of Sebastopol. That night the Russians evacuated the city, or rather its blazing ruins. Except for the surrender of Kars in Circassia, after its gallant defence by the Turks under Colonel Williams, a British officer, the war ended with the fall of Sebastopol. In March 1856 a treaty of peace was signed at Paris, by which Russia lost all she had gained or attempted to gain; but the article prohibiting Russia from building arsenals or having war-ships on the Black Sea (q.v.) was abrogated in 1871. See Kinglake's *Invasion of the Crimea* (8 vols. 1863-87), and books on the war by Sir E. Hamley (1891), Sir D. Lysons (1895), Stelling (1895), and Sir W. H. Russell (1855 and 1895).

**Criminal Conversation.** See ADULTERY.

**Criminal Law** is that branch of law which deals with crimes and their punishment. Crimes are a specific class of wrongful acts which the state, in the public interest, intervenes to punish. The object of criminal law or of criminal proceedings always is the punishment of the offender.

On the other hand, the object of civil law or of civil proceedings is the redress of the wrong by compelling compensation or restitution to the injured party. In the case of all crimes the law treats the wrong-doing as not merely an injury to an individual, but as a matter of public concern. Where a crime has been committed the person injured cannot prevent proceedings being taken to secure punishment, for the criminal has to answer for his deed to the state itself.

Prior to any distinction between criminal and civil procedure, prior even to legal procedure of any kind, the principle of retaliation or private vengeance was operative. The system of *talis*—that is, of inflicting an evil upon the wrong-doer in proportion to the wrong he has inflicted on you, 'an eye for an eye and a tooth for a tooth'—is found in the early laws of the Hebrews, Greeks, and Romans, in early systems of Teutonic law, and, indeed, universally in primitive communities. In Rome, as in England, the early law recognised and regulated this system of self-help which the state was as yet not strong enough to prevent or repress. A notable advance in civilisation was made when a fixed money payment for specified injuries was substituted for the *talis*, so that private vengeance could be exacted by the injured party only where the culprit failed to offer the prescribed reparation. In the Anglo-Saxon era the right of private vengeance for an injury was called *fēth* ('feud'). But the law gradually compelled the injured party or his kinsmen to accept a pecuniary *Wer-gild* (q.v.) in lieu of blood revenge; and, when the idea gained ground that wrong-doing was injurious not only to the victim of the wrong, but also to the state, a fine, known as the 'wite,' was also exacted on behalf of the community from the wrong-doer.

When the state intervenes directly to punish certain classes of wrongful acts, these acts become crimes as distinct from mere private wrongs. In the case of such acts, the idea of punishment supersedes the idea of compensation to the community or to the injured party. Thus the distinction between crimes and civil wrongs does not consist of any intrinsic difference in the nature of the wrongful acts, but in the different aims of the legal proceedings taken upon them—the aim being, in the case of a crime, the punishment of the wrong-doer, and, in the case of a civil wrong, the enforcement of the right of the injured party to redress. Hence a wrongful act may be either a crime or a civil wrong; or it may be, and often is, both. Hence, too, the particular classes of wrongs which are recognised as crimes vary from one legal system to another, and, under any one legal system, vary from era to era. Thus, theft in Roman law was a civil injury, but in English law is a crime. Again, many acts are now criminal in England which formerly either were not wrongs at all, or were wrongs giving rise merely to claims for damages.

The strength of criminal law lies in its prohibitions and punishments being in accordance with the moral sense of the community. The principles which should determine the measure and method of criminal punishment have been much discussed. Beccaria's work, *On Crimes and Punishments*, published in 1764, has exercised a strong influence throughout western Europe in securing more humane consideration for criminals; and English jurists of the 18th century, such as Bentham and Romilly, accomplished much towards the abolition of the aimless severities which formerly disfigured the criminal law of England. But the question as to the principles on which penalties should be awarded for crime is still unsolved. The main ends and purposes of criminal punishment are, it is generally admitted, to deter, to prevent, and to reform; but it is no less generally recognised that the methods

of punishment hitherto in use in criminal law are clumsy and imperfect instruments to these ends. To some extent, indeed, these several ends tend in practice to be antagonistic. Thus it is difficult to devise forms of punishment which shall be at once deterrent and reformatory, at once dreaded and yet not injurious, mentally, morally, or physically. Again, it is urged with truth that punishment can be effectual as a deterrent only if it is certain in operation; but it is difficult to secure certainty in the administration of criminal law, and at the same time to adapt the punishment to the special needs of the individual culprit. In recent years, in England and Scotland, attempts have been made to surmount these difficulties by instituting various classes of places of penal detention—the convict prison, the reformatory, the industrial school, the Borstal institution, &c.; by making special provision for the trial and punishment of youthful offenders (8 Edw. VII. chap. 67); by empowering criminal courts, having regard to the character, antecedents, age, health, or mental condition of the person charged, to refrain from inflicting punishment or to release him 'on probation' on his entering into a recognisance to be of good behaviour, and to appear for sentence when called on during a certain period (7 Edw. VII. chap. 17); and by enabling a court, on pronouncing a sentence of penal servitude on a person who is an 'habitual criminal,' to add a further sentence of 'preventive detention' after the end of the penal servitude, if it deem such a course expedient for the protection of the public (8 Edw. VII., chap. 59).

Criminal law deals both with the substantive law of crimes and with the procedure by which offenders are tried and brought to punishment. The substantive portion of criminal law defines the conduct which constitutes each particular crime (see *CRIME* and the several articles on particular crimes, *MURDER*, *THEFT*, *PERJURY*, &c.), and also the general elements necessary to a criminal act, the facts which exempt from criminal responsibility, such as tender age, compulsion, or lunacy, and the facts which justify an act otherwise criminal, such as self-defence. In general, the law punishes only acts and not omissions, and ignorance that an act is criminal is no excuse. A principal—i.e. the person by whom the criminal act itself was done—and accessories before the fact are all equally punishable. In English law an accessory after the fact—i.e. a person who, knowing that a felony has been committed, shelters the felon or actively assists him in escaping punishment—is also liable to punishment.

Criminal procedure in English law differs from that in most other systems of law in resembling more closely the procedure of an ordinary civil action. In Scotland, as in France and other Continental countries, criminal proceedings are instituted by public officers, and a criminal prosecution is of the nature of a public inquisition by the authorities of the state. Thus in Scotland the Lord Advocate and the subordinate public prosecutors acting under his control are directly responsible for the investigation of suspected crimes and for the institution and conduct of criminal prosecutions. In England, on the other hand, the duty of demanding the punishment of a criminal is laid primarily on the person injured by the criminal act, though the proceedings are taken in the name of the king as representing the state, and every citizen, whether injured or not, has a right to set the law in motion. The law may also be set in motion by the police. By recent statute, a public officer, the Director of Public Prosecutions, has authority to institute or carry on criminal proceedings in any court and intervene in any criminal proceeding actually commenced, and take the further conduct of the

case out of the hands of the private prosecutor or the police (42 & 43 Vict. chap. 22; amended by 47 & 48 Vict. chap. 58, and 8 Edw. VII. chap. 3).

Both in England and Scotland the procedure by which offenders are brought to punishment is of two kinds—ordinary (or, as it is called in Scotland, solemn) and summary. In both countries the fundamental distinction between these two modes of proceeding is that, in solemn, or ordinary, procedure the guilt or innocence of an accused person is determined by a jury, while in summary procedure the accused is condemned or acquitted by the magistrates (or, in Scotland, by the sheriff) without the intervention of a jury. In many other respects the proceedings for the trial of an offence differ according as the offence is tried by a jury or summarily. In particular, in the former case, the accused must be formally committed for trial, and the trial proceeds on an indictment; in the latter case, the accused need not be formally committed, and the trial proceeds on an information or complaint.

The vast majority of criminal cases, being offences of a more or less trivial character, are disposed of summarily. In England and also in Scotland the method of procedure in courts of summary jurisdiction is minutely regulated by statute with a view to secure simplicity and despatch, and the procedure in a summary trial is very similar in both countries. Where the accused is tried by a jury on an indictment, the procedure differs in England and Scotland. In England the magistrate before whom a charge is made issues a summons to the accused to attend or grants a warrant for his arrest; or, as frequently happens, the accused is arrested without a warrant. When the accused appears before the magistrate the witnesses are examined in his presence, and he is at liberty to put questions to them either personally or by counsel. The statements of the witnesses, technically termed depositions, are read over to, and signed by, the witnesses respectively, as well as by the magistrate. The accused may then say anything he desires in answer to the charge, he being warned that whatever he says will be taken down in writing and may be used in evidence against him. Whatever the accused then says is taken down in writing, and signed by the magistrate, and may be read at the trial without further proof. The prisoner's witnesses, if any, are next examined. Thereafter the justice (or, if there be more than one, the majority) may either discharge the accused or commit him for trial, which practically means that he is either sent to prison to await his trial or is admitted to Bail (q.v.). The commitment is for trial either at quarter sessions or at the assizes. A written or printed accusation, called a 'bill of indictment,' setting forth the precise charge which the prisoner is called upon to answer, is laid before a grand jury consisting of from twelve to twenty-three persons. The grand jury, after being sworn in open court and 'charged' by the presiding judge, retire to their room, and, after hearing the witnesses for the prosecution, find either a 'true bill' or 'no bill.' The prisoner himself has no right to give evidence before the grand jury; but twelve of them must agree before they find a 'true bill' or 'ignore' a bill. (The Grand Juries (Suspension) Act, 1917, provided for the suspension of grand juries during the war and for six months after its termination.) Where the grand jury have found a true bill, the next step is to 'arraign' the prisoner—i.e. to call him to the bar of the court, read to him the indictment, and ask him whether he is guilty or not of the offence charged. If he pleads 'not guilty,' petty jurors, twelve in number, are sworn, and the trial proceeds before the judge and jury in open court. The counsel for the prose-

cution 'opens' by an address directing the attention of the jury to the main questions at issue, and then examines the witnesses for the prosecution, who are afterwards cross-examined and re-examined. Counsel for the accused then examines the witnesses for the defence, including the accused himself if he desire to give evidence on oath. This right was conferred on the accused by the Criminal Evidence Act, 1898, and it is the duty of the judge to make it clear to him that he has this right. Where witnesses, other than the accused, give evidence as to the facts, counsel for the accused opens the case for the defence, and at the close of the evidence may make a second speech on the evidence, and the prosecuting counsel has a right to reply on the whole case. If no evidence has been adduced for the prisoner other than his own evidence, the address of the counsel for the defence is the last. Thereupon it is the duty of the judge to sum up the case to the jury, who then consider their verdict, which must be unanimous. If the verdict be 'guilty,' the accused is sentenced; if it be 'not guilty,' he is discharged. The Poor Prisoners' Defence Act, 1903, makes provision for a prisoner who is without means, and can show a fair defence, having a solicitor and a counsel assigned to him, and the expenses of his defence being paid out of public funds. By an Act of 1907 (7 Edw. VII. chap. 23)—which, however, does not extend to Scotland or Ireland—a Court of Criminal Appeal has been created for England. To this court a person convicted on indictment has an unfettered right of appeal on any question of law; a right, in case of his obtaining leave either from the Court of Criminal Appeal or from the judge who tried him, to appeal on any question of fact, or of mixed fact and law; and a right, on obtaining leave from the Court of Criminal Appeal, to appeal against the sentence passed on him.

In Scotland the proceedings in a criminal prosecution on indictment commence with an application for warrant to arrest, which may be granted by any magistrate. The accused, on being arrested, is entitled at once to the services of a law-agent, and such law-agent is entitled to have a private interview with the accused before he is examined on declaration and to be present at that examination. The examination on declaration takes place before a sheriff or a magistrate, who must give the accused warning that he is not bound to answer any questions, and that what he says may be used in evidence against him. What he says, or a statement by him that he declines to answer, is written out and read over to him, and is signed by him and by the sheriff or magistrate. The accused is entitled to apply for Bail (q.v.) immediately after he has emitted a declaration. If bail is not allowed, the accused is, in the usual case, committed to prison either for further examination or until liberated in due course by law. Committal for further examination means that he is detained for such limited period as is necessary to enable the procurator-fiscal to examine witnesses and determine whether the evidence is sufficient to justify him in asking that the prisoner be committed for trial. The 'precognitions'—i.e. the evidence—of the several witnesses are taken by the procurator-fiscal in private and separately, and, except in exceptional circumstances, a witness is not put on oath at precognition. Where the first committal is only for examination, the magistrate, if he thinks that the precognitions show a *prima facie* case, grants a warrant committing the accused for trial. The precognitions are then sent to the crown agent to be submitted to crown counsel, who may order the accused to be liberated, or may order the case to be tried by sheriff and jury, or may indict the case for trial in the High Court of Justiciary.

Where the trial is in the High Court, the indictment, which runs in the name of the Lord Advocate, is prepared by crown counsel, and a copy of it is served on the accused. It sets forth the crime charged, and contains a list of the witnesses to be examined at the trial and a list of the articles or documents to be produced at the trial. Two 'diets' are fixed. The first of these diets, called the 'pleading diet,' is held before the sheriff. If the accused pleads guilty at this diet, he is sentenced by the sheriff or remitted to the High Court for sentence. If he pleads not guilty, the case is continued for trial at the second diet, at which diet, if the accused adheres to his plea of not guilty, the case is laid before a jury of fifteen persons, empanelled to try it. The witnesses for the prosecution are examined, and then the witnesses for the defence. The accused himself is a competent but not compellable witness. When all the evidence has been led the prosecuting counsel and the counsel for the accused address the jury, the former speaking first and not having any right of reply. The judge sums up, and the jury return their verdict, which need not be unanimous, but may be by a majority. If the verdict be 'not guilty' or 'not proven,' the accused is assoiled and dismissed. If it be 'guilty,' sentence is pronounced. A sentence in the High Court cannot be reviewed, except in case of a sentence of 'preventive detention,' pronounced under the Prevention of Crimes Act, 1900, on a prisoner who is an 'habitual criminal,' against which an appeal lies under that act to a court of appeal consisting of not less than three judges of the High Court.

**Criminology** is a recently invented term denoting a new science—the branch of anthropology which deals with crime and criminals, sometimes called 'criminal anthropology.' The science is largely based on the researches and views of Dr Cesare Lombroso, born of Jewish stock at Verona in 1836, who, after serving as an army surgeon and holding posts at Pavia and Pesaro, had at his death in October 1909 been for many years professor of psychiatry and of criminology at Turin. He wrote numerous works on insanity, criminal insanity, the anthropometry of criminals, the close connection between insanity and genius, the criminal (1875), crime, its causes and remedies (1899), as well as spiritualism. He held that the congenital habitual criminal is marked by conspicuous physical and mental defects. Arrested cranial development and deformity, heavy jaws, ugly features, and many other minor abnormal physical characters are associated with moral insensibility, low intelligence, vanity, and irregular emotional peculiarities verging on insanity. The occasional criminal who yields to severe or special temptations was treated as belonging to a wholly distinct category. These anthropological views, by no means universally admitted, would naturally lead to somewhat sweeping changes in the treatment of criminals.

See, besides the works of Lombroso, *The Criminal*, by Havelock Ellis (1890); *Modern Theories of Criminality*, by De Quiros (1911); *Criminal Psychology*, by Hans Gross (1911); and other works translated by the American Institute of Criminal Law and Criminology; *The English Convict*, by Charles Goring (1913; new ed. 1919); also the articles PRISONS, REFORMATORY AND INDUSTRIAL SCHOOLS, INSANITY, CAPITAL PUNISHMENT.

**Crimp**, a person who usually keeps a sailors' boarding-house, and who professedly occupies himself in finding employment for seamen. Crimps, or 'runners,' as they are often called, and the disreputable persons who are associated with them, live by pandering to the follies and vices of the lower and less provident class of seamen. Their object is to get hold of the sailor and his effects,

keep him by means of drink or drugs in their power until his wages are paid, and fleece him of his money, and even of his clothes.

**Crinan Canal**, an artificial waterway, 9 miles long, in the west of Argyllshire, between Loch Gilp, a branch of Loch Fyne, and Loch Crinan, in the Sound of Jura, at the head of the peninsula of Kintyre. Constructed in 1793-1801 at a cost of £183,000, to avoid the circuitous passage of 70 miles round the Mull of Kintyre, it has 15 locks, and admits vessels of 200 tons. In 1859 the three reservoirs feeding it burst, and government had to repair the damage at a cost of £12,000. The receipts seldom cover the year's expenditure. Enlargement has been proposed.

**Crinoidea** (Gr., 'lily-like'), a class of Echinodermata, sometimes called feather-stars or sea-lilies, and well known in fossil form as encrinurites or stone-lilies. While agreeing in general structure with starfishes and other Echinoderms, the Crinoids present many peculiarities. They are fixed permanently or temporarily, mouth upwards, by a stalk, which is usually jointed. The visceral mass is enclosed in a cup at the apex of the

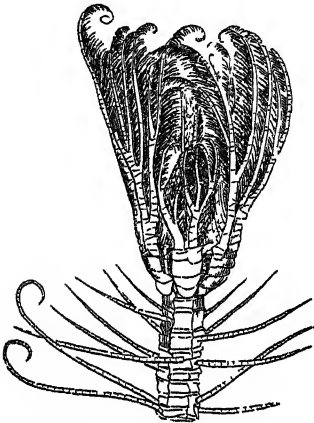

Fig. 1.—Pentacrinus.

stalk. As in most other Echinoderms, there are numerous limy plates, forming the stalk, the supporting cup, the framework of the arms, &c. The anus lies near the mouth. The 'arms,' though typically five (towards 200) by branching; they usually bear lateral pinnules, which produce a feathered appearance. Water enters the body-cavity by numerous pores on the oral surface, and passes by 'stone-canals' into the ring round the mouth which sends a radial vessel up each arm. The tube-feet are small and delicate, and serve for respiration and food-wafting. Besides the usual nerve-ring round the mouth and the radial cords arising from it, there is an 'aboral nervous system' which controls the movements of the animal. The sexes

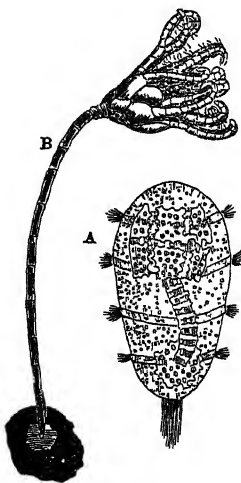

Fig. 2.

A, free-swimming larva, with skeleton of adult forming inside; B, fixed stalked young (Pentacrinus-like) stage.

are separate and similar, and the germ-cells are formed in the pinnules of the arms.

**Mode of Life**—Most of the living Crinoids fix themselves in larval life and remain attached. The Comatulids, however, break off from their stalk at an early stage, and in *Holopus* the stalk is represented by a leathery non-calcified outgrowth from the calyx. The stem of the stalked forms is usually anchored to a rock or other foreign object, but in some cases the animal grows more loosely on a muddy bottom. Like the extinct forms, the modern stalked Crinoids grow in masses, forming beds of sea-lilies on the ocean floor. Over a hundred specimens have been dredged in a single haul. When they move about, as in the Comatulidæ, they do so by alternately bending and straightening the arms. The food, which consists of minute organisms (protozoa, diatoms, small crustacea, &c.), is wafted down ciliated grooves on the pinnules and arms to the mouth. The known larvæ are actively free-swimming by means of cilia. Comatulata and some others are the hosts of curious parasitic Chaetopod worms (Myzostomidæ), which cause deformities on the arms. Like many other Echinoderms, the Crinoids have the power of regenerating lost parts. Broken-off arms may be replaced, and even the renewal of the visceral mass has been observed.

**Important Forms and Classification.**—The best-known genus is the cosmopolitan *Antedon* or *Comatulata*, of which *A. rosacea* is the most abundant

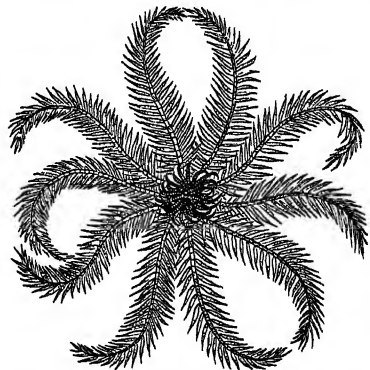

Fig. 3.—Free Adult, showing wreath of anchoring hooks.

species, frequently dredged off British coasts. Along with the large genus *Actinometra* and some others less important, *Antedon* represents the family of Comatulids, which differ from other Crinoids in being stalked only in their youth. Professor J. Vaughan Thompson has the credit of having discovered the young stalked stage of *A. rosacea*, and thus revealing the existence of a most interesting habit. The free *Antedon* swims gracefully by bending its ten arms, and then settles down again for a while, anchoring itself by means of an inferior wreath of clawed attaching processes. Among permanently stalked Crinoids may be mentioned the genus *Pentacrinus* (e.g. *P. asterius*), from the Atlantic and Pacific, often at great depths; *Rhizocrinus* (e.g. *R. lofotensis*), from the Atlantic, usually abyssal; *Holopus*, from the Caribbean Sea, with very massive arms, and only a single extant species.

**Distribution.**—Most of the modern stalked Crinoids are distinctively deep-water animals, and many have been dredged from over 2000 fathoms. The stalk serves to raise the essential part of the animal out of the fine ooze on the sea-floor. Many Comatulids frequent shallow water; thus the British Rosy Feather Star is found at about 10 fathoms. The peculiar *Holopus* is also found in shallow water in the Caribbean Sea.

The great majority of the Crinoids are extinct, and the class must be regarded as decadent. As compared with about a dozen recent genera, there are over 200 known as fossils. They were represented in the Lower Cambrian, and attained great development in Silurian, Devonian, and Carboniferous times. Besides Crinoidea in the strict sense, there are allied classes of great zoological interest which are wholly extinct—the Cystoidea, Blastoida, Edrioasteroidea, &c. The last-named class, also known as Thecoidea, is probably nearest the root-stock of the Echinoderms, from which the free forms or Eleutherozoa (starfishes, sea-urchins, &c.) diverged in one direction, and the stalked forms or *Pelmatozoa* (Crinoids, Cystoids, &c.) in another.

See **ECINODERMATA**; **STARFISH**, &c.; F. A. Bather, 'Echinodermata,' in *Lankester's Treatise on Zoology*, part II. (1900); E. W. MacBride, 'Echinodermata,' in vol. I. of *Cumbridge Natural History* (1906); F. Jeffrey Bell, 'British Echinodermata,' *Brit. Mus. Catalogue* (1892); P. H. Carpenter, 'Stalked Crinoids,' *Challenger Reports*, xi. (1884); Jaekel, *Stammesgeschichte der Pelmatozoen* (1889); Wachsmuth and Springer, *Revision of Palaeocrinoidea* (Phila. 1879-85).

**Crinoline**, the name originally given by the French *modistes* to a fabric of horse-hair (Fr. *crin*, 'hair'), capable of great stiffness, and employed to distend women's attire. It was applied in a general way to those structures of steel wire or hoops, by means of which women between 1855 and 1866 attained enormous dimensions—12, even 15 feet in circumference. Such fashion of expansion was not new. There was the *fardingale* of Queen Elizabeth, when the upper part of the body was encased in a cuirass of whalebone, which was united at the waist with the equally stiff fardingale of the same material, descending to the feet in the form of a great drum. We next hear in 1711 of 'that startling novelty the hoop petticoat,' which differed from the fardingale in being gathered at the waist; and by 1744 hoops had grown so extravagant, that a woman occupied the space of six men. An elongated oval form also came into fashion, raised at each side to show the high-heeled shoes. In 1780 we find hoops of cane advertised to 'outwear the best sort of whalebone.' About 1796 hoops had been discarded in private life, but were still the mode at court until, in the time of George IV., they were abolished by royal command.

**Crinum**, a genus of bulbous-rooted amaryllids (sometimes included under *Sternbergia*), chiefly tropical, and frequently cultivated in hothouses—e.g. *C. latifolium* of India, *C. scabrum* of Brazil, &c.

**Cripple Creek**, a city, capital of Teller county, Colorado, 40 miles by rail N. by W. of Florence. It is a gold-mining centre. The population has fallen from 10,000 in 1900 to 2300.

**Cris-cross Row**. See **HORNBOOK**.

**Crispi**, **FRANCESCO** (1819-1901), statesman, was born at Ribera in Sicily, and was called to the bar in Palermo, but joining in the revolutionary movement of 1848, had to flee to France. He organised the successful movement of 1859-60, and re-entered Sicily with Garibaldi. He was conspicuous in the history of Italy as deputy, president of the chamber, minister, and in 1887-90, and again in 1894-96, premier. He represented the Left, was strongly anti-clerical, and maintained the alliance with Germany even at the cost of the alienation of France. Strenuous efforts were made by his enemies to discredit him by connecting him with a series of bank scandals. See *Life* by Stillman (1899), and his *Memoirs*, compiled by Palamenghi-Crispi (trans. 1912-14).

**Crispin**, saint and martyr under Diocletian, fled along with his brother Crispinian, from Rome into Gaul, where they worked as shoemakers in the

town now called Soissons, and where Crispin distinguished himself by his exertions for the spread of Christianity, as well as by his works of charity. In A.D. 287 he and his brother suffered martyrdom by being thrown into a caldron of molten lead. Both are commemorated on the 25th October. Crispin is the universally recognised patron saint of shoemakers.

**Cristofori**, or **CRISTOFALI**, **BARTOLOMEO**, harpsichord-maker, was born at Padua in 1655, and died at Florence in 1731. He is regarded as the inventor of the pianoforte.

**Critchett**, **GEORGE**, ophthalmic surgeon, born in London in 1817, became F.R.C.S. in 1844, and was assistant-surgeon and (1861-63) surgeon to the London Hospital. He early devoted his attention to ophthalmology, and was attached to the hospital at Moorfields from 1846; in 1854 he published a course of lectures on *Diseases of the Eye*, and from 1876 he was ophthalmic surgeon and lecturer at the Middlesex Hospital, where his operations acquired a European fame. He died 1st November 1882.

**Critias**, one of the pupils of Socrates, but unfortunately one who was rather a hearer than a doer of his word. On his return to Athens from banishment, he put himself at the head of the oligarchical party, and was afterwards the most rapacious and cruel among the thirty tyrants set up by the Spartans (404 B.C.). In the same year he fell at Munchia, resisting Thiasylus and the exiles. Critias had a high reputation as an orator, and besides wrote poetry.

**Critical Temperature** is that temperature below which a substance may, and above which it cannot, be liquefied by pressure alone. This temperature for carbonic acid gas, for example, is 30.9° C.—i.e. below that temperature, the liquefaction of the substance may be easily effected if sufficient pressure be applied; but above it the substance cannot be liquefied, no matter how great be the pressure to which it is subjected. The discovery of the critical temperature by Dr Andrews in 1869 first gave the means of distinguishing between a true gas and a true vapour; for the former is a substance above, the latter one below, its critical temperature. When any substance is at this temperature it is in the critical state—i.e. its passage from liquid to gas, or *vice versa*, is one in which the two parts, liquid and gaseous, so merge into one another as to render them optically indistinguishable. The critical temperatures of oxygen, hydrogen, and nitrogen (formerly termed 'permanent' gases) are all extremely low, and hence liquefaction can only be effected (as it has already been) by the application of intense cold as well as considerable pressure. On the other hand, such vaporous bodies as sulphurous anhydride, alcohol vapour, ether vapour, &c. can, provided the pressure be sufficiently great, be liquefied at ordinary air temperatures, since these are much below their critical temperatures. See **GAS**, **VAPOUR**, **MATTER**.

**Criticism**, **BIBLICAL**. See **BIBLICAL CRITICISM**.

**Criticism**, **LITERARY**, is generally held to begin with Aristotle, and by Aristotle's teaching, rightly or wrongly understood, it has been dominated ever since. Earlier instances can, of course, be traced. The work of the sophists and the epideictic orators implies the existence of criticism, and it can be seen, not yet disengaged from other operations of the mind, in the *Frogs* of Aristophanes and the *Republic* of Plato. Even Aristotle's *Rhetoric* is not written from a strictly literary standpoint, for it is a treatise of the art of persuading. In the *Poetics* he founds a masterly theory on the actual practice of poets, mainly, in the surviving fragment, tragic and epic poets, thereby at once showing

successors an example of the true method and throwing an obstacle in their way. For critics of the European nations found it so much easier to see what Aristotle had shown them in Greek tragedy and epic than to look for anything new in their own literatures, that they narrowed their outlook to the scope of Greek literature, and made repressive rules of his observations. The learned men of Alexandria, to whom the active spirit of literature was denied, busied themselves mainly with minutiae of technique. If they did not escape pedantry, they yet did much useful laborious scientific work. Technique again absorbs the attention of Dionysius of Halicarnassus. It is far otherwise in the author (Longinus, it may be) of *On the Sublime*, the greatest, after Aristotle, of Greek critics, who has perhaps never been excelled in generous insight.

The criticism of the Romans is of much smaller value. Apart from casual censures and dicta, Cicero, Horace, Seneca, Tacitus (if he wrote *De Oratoribus*), and Quintilian deserve mention—Horace for the mischievous tyranny long after wielded by the brilliant philistinism of his *Ars Poetica*, Quintilian for his catholicity in appreciation. From Alexandria the line of grammarians and commentators passes to Rome. Writers of miscellaneous second-hand lore, Aulus Gellus, Macrobius, Martianus Capella, hand on the torch to the Dark Ages, which are little enlightened by its glimmerings. Dante alone, before the new learning—unless Boccaccio be counted a second—was a notable critic.

The influence of Aristotle was strong among the Italians of the Renaissance, who expanded his teaching as to unity of action into the doctrine of the three unities, and by insisting on the supremacy of epic, stained modern poetry out of its natural course. Important names are those of Vida, Trissino, Daniello, Robortello, Cinto, Minturno, Scaliger, Castelvetro, Tasso, and Patrizzi.

English criticism before the Renaissance had been confined to a few random utterances, seldom more than perfunctory compliments. But after it is fairly begun by Wilson, Cheke, and Ascham, Italian influence becomes strong. Poetry is defended, its principles examined into, and special problems, such as the legitimacy of rhyme and the possibility of naturalising classical metres, are discussed by such men as Gascoigne, Lodge, Spenser, Gabriel Harvey, Sidney, Webbe, Nash, Puttenham, Campion, Daniel, Jonson, and Bacon. The prestige of English is maintained, and it is distinctly asserted that 'Poesy must not be drawn by the ears; it must be gently led, or rather it must lead; yet one can see in this enlightened and tempered classicism the threat of a criticism that should claim to legislate for poets rather than 'seek to know what they do and how they do,' as Sidney had expressed its function.

Aggressive tyrannical dogma, like political absolutism, spread from France. Earlier schools, those of the *rhétoriciens* and of Marot, had expressed their tendencies in critical as well as productive work; the Pléiade doctrines had been set forth by Du Bellay, Ronsard, and Vauquelin de la Fresnaye. But *enfin Malherbe vint*, and thenceforward the work of 17th-century Frenchmen was to develop the teaching of 16th-century Italian Aristotelians into a closed and rigid system. Even the genius of Corneille submitted itself to the rules of Chapelain, who was backed by Richelieu and the Academy; and the strong prosaic common-sense of Boileau, the destroyer of Chapelain's reputation, only served to make him the Horace of neoclassicism. A stringent code was constructed by D'Aubignac, Rapin, Le Bossu, Bouhours, and other pedants, and in the next century such critics as

Voltaire, Buffon, Marmontel, La Harpe, and Suard were more or less complacently orthodox.

In England the classical theory had to wait for practical application until the weakening of the romantic impulse gave opportunity and its eccentricities excuse. In Ben Jonson the classical drift is already clearly seen. After the Restoration the verse-essays of Mulgrave and Roscommon are types of a large body of criticism written to French dictation. Boileau's yoke sat firmly, though lightly, upon Dryden, who has been called the father of English criticism; and both he and Pope borrowed directly from the French. Ryme was a pedant; the rancorous Dennis perhaps something better; Addison a classicist with a difference; and Johnson a critic whose greatness was confined within the limits that classicism imposed.

A change begins with Lessing in Germany and Diderot in France. With these may be named Schiller, Richter, the Schlegels, and Heider, Mme. de Staël, and Chateaubriand. In England, after premonitory utterances by literary antiquaries like Gray, Hurd, and Thomas Warton, romantic criticism burst forth in Wordsworth's preface to the *Lyrical Ballads*, to be supplemented and far outshone by Coleridge, one of the greatest of critics, indebted partly to German aesthetic thinkers. While the *Edinburgh* under Jeffrey, the *Quarterly* under Gifford and Lockhart, and *Blackwood's* in the hands of Wilson and his colleagues, were either determinedly reactionary or waveringly progressive, romanticism had on its side such critics as Lamb, Leigh Hunt, Shelley, and Hazlitt. To Landor and De Quincey succeeded Matthew Arnold and Walter Pater, Swinburne and Watts-Dunton.

In France, since the revolt of Hugo and the romantics, Sainte-Beuve has kept in mind the psychology of the individual, Taine that of the people in its environment, and Brunetière the evolution of genres. In Italy Croce's criticism is philosophical. The Danish critic Georg Brandes has been notable among those who look at the literature of the world as a whole. Germany has a tendency to be drawn aside from criticism into aesthetics on the one hand, while on the other it has begun to teach America and other countries that self-denying species of criticism which is rather a branch of pure science than anything else.

See the articles on the critics named; also Spingarn, *Literary Criticism in the Renaissance* (1899; new ed. 1908), and *Critical Essays of the Seventeenth Century* (1908-9); Saintsbury, *History of Criticism* (1900-4), and *History of English Criticism* (1911; new ed. 1922); Gregory Smith, *Elizabethan Critical Essays* (1904).

**Croaghpatrick**, a celebrated Irish mountain connected with the story of St Patrick's missionary work. It stands about 4 miles SW. of Westport, in the south of County Mayo, and is 2510 feet high.

**Croatia-Slavonia**, a region of Yugoslavia, lying between the Adriatic Sea on the SW., where Croatia has a seaboard of about 84 miles, and Hungary on the NE. Area, 16,600 sq. m. Pop. (1921) 2,642,648, including Veglia and other islands. The surface of Croatia falls mainly into the wooded mountain district to the north of the Kulpa, with offshoots from the south-east Alps, and a calcareous plateau, belonging to the Karst region, to the south. To the Alpine system belong the Matzel, Ivinica, and Kalnik groups in the north; to the Karst system belong the Liburnian Karst (5007 feet), along the coast from Fiume (q.v.) to Novi, and the Velebit Mountains to the south-east, with the peak of Sveto Brdo (5751 feet) near the Dalmatian boundary. The region belongs mainly to the basin of the Danube, its most important rivers being the Drave and Save, with their affluents; the Gatschka, Likka, and others belong to the Karst, and the Zermanja, in the

south-west, flows into Dalmatia. In Slavonia extensive marshes are found along the main rivers. Warm mineral springs are numerous, and earthquakes, especially about Zagreb or Agram (q.v.), are frequent. The Adriatic coast is poorly supplied with harbours, and exposed to the blasts of the Bora (q.v.). The climate along the coast and in the north is mild, Zagreb having a mean temperature of 52° F.; in the Karst the yearly mean is from 42° to 46° F.

The soil is in general very productive. Corn, maize, pulse, millet, flax, hemp, tobacco, and grapes are cultivated; large quantities of wood are exported, the rich forests being for this industry recklessly despoiled; and horses and cattle are successfully raised, while the oak-forests of Slavonia support great droves of swine. Silk-culture is progressing, and bees are largely kept in the heath districts. Only in ores and minerals is the region poor; iron, silver, copper, lead, zinc, sulphur, and coal are all worked, but in small quantities. Much of the weaving is done at home, and the other manufactures are not important. The trade is chiefly in land products, Slavonia exporting also a brandy made from plums. The bulk of the people are Slavs; both Croats (originally *Chorvats*, 'mountaineers,' from *chora* or *gora*, 'a mountain') and Slovenes are tall and strong, honest, and good-natured, holding much of their land in common, and dwelling for the most part in scattered hamlets. The west is Roman Catholic; the east, Orthodox. Education is very backward; in 1890, 40 per cent. of the male inhabitants could neither read nor write. A number of railways, however, now penetrate the country, and the interest in education and in the national language and literature has increased. There is a university at Zagreb.

Croatia and Slavonia were for the most part included in the Roman province of Pannonia; in the 7th century the territory was taken possession of by the Slavonic races. The Croats shook off the Byzantine yoke about 900, and in the following century extended their rule over Dalmatia, built a strong fleet, which they employed first for piracy, and afterwards for trade, and had their king, Dzirslav, recognised by the Eastern court in 994. His son, Cresimir Peter, one of the greatest national heroes, was acknowledged as king of Dalmatia, as were also his successors until 1091, when the kingdom was taken over by Hungary. Slavonia was made a province of Hungary about the same date, but in the 17th century a great part of the land was held by the Turks, who only in 1699 resigned all territory north of the Unna. Croatia, Slavonia, and Dalmatia were united as the kingdom of Illyria from 1767 to 1777. Afterwards Croatia and Slavonia were regarded as part of the kingdom of Hungary; but among the Croats a feeling of hostility to the Magyars grew up, which asserted itself in 1848-49. In reward for services during the Magyar revolt Croatia-Slavonia was made an Austrian crown-land, and practically so remained until 1868, when the connection with Hungary was restored, Croatia sending deputies to the Hungarian diet. There was a national diet at Zagreb, the official language being Croatian. In 1883 there was a popular movement against Magyar domination. These Serbo-Croat aspirations became more pronounced in the 20th century, and led to repressive measures by the Magyar government; and in 1912 the censorship of the press was drastic, the university of Agram was closed, the new diet was dissolved before it met, and the constitution was suspended, so that the country was under the dictatorship of the ban (appointed by the Magyar government). The constitution was restored in 1913. Nationalists had for a time been content to aim at turning

the dual into a trial monarchy. But on the dissolution of Austria-Hungary the Croatian diet declared the independence of Croatia, Slavonia, and Dalmatia (30th October 1918); and these regions became parts of Yugoslavia or Jugoslavia, or the kingdom of the Serbs, Croats, and Slovenes (see SERBIA). The Military Frontier, established for defence along the Turkish border in the 16th century, was inhabited by military colonists always ready for war, who enjoyed special privileges: it was in 1881 incorporated with Croatia and Slavonia. See BAN; and for language, SERBIA.

**Croce**, BENEDETTO, was born at Pescasseroli, a small township in the province of Aquila in the kingdom of Italy, 25th February 1866. He descended from an ancient family, catholic and conservative, long established in the Abruzzi. His parents moved to Naples in his childhood. In 1883, at the age of seventeen, he lost both his parents and his only sister in the earthquake of Casamicciola in the island of Ischia, and himself lay buried for some hours in the ruined masonry. After his rescue he was taken to live at Rome in the house of his maternal uncle, Silvio Spaventa, who became his tutor. At that time another uncle, a priest, the famous philosopher Bertrando Spaventa, was lecturing to large audiences in the university of Rome on the Hegelian philosophy. Croce tells us that there was a certain estrangement between the brothers, and that he never came under the direct influence of the philosopher uncle. His early studies and his writings before 1900 were mainly historical, and his special researches were devoted to the elucidation of the history of Naples. His first distinctively philosophical writing, the origin of the new philosophy which has made him famous, was a paper read to the Academy of Naples in 1900 and published in the volume of its *Atti*. It was entitled '*Tesi fondamentale di un Estetica come scienza dell'espressione e linguistica generale*.' In the succeeding years this article developed into *The Philosophy of Mind*, which consists of four volumes. All have been translated by Mr Douglas Ainslie. They are (1) *Aesthetic*, (2) *Logic*, (3) *Philosophy of Practice—Economics and Ethics*, and (4) *Theory and History of History*. The philosophical writings, however, form only a part of Croce's literary activity. His complete works to-day (1923) reach the number of twenty-nine volumes. They are arranged in four series: (1) *Philosophy of Mind*, (2) *Philosophical Essays*, (3) *Writings on Literary and Political History*, (4) *Miscellaneous*. These do not include a number of shorter but important occasional publications. Since 1903 he has edited *La Critica*, a bi-monthly review of Literature, History, and Philosophy, largely composed of his own signed articles. Also he has edited a collection of about thirty volumes of '*The Classical Works of Modern Philosophy*,' for the first of which, Hegel's *Encyclopædia of the Philosophical Sciences*, he himself made the translation and wrote the Introduction. Since the Great War he has taken an active part in politics. He is a senator of the kingdom of Italy, and in 1920 he accepted the portfolio of Minister of Public Instruction in the Giolitti government. He resigned with the fall of that government in 1921.

In order to appreciate the distinctive character of Croce's philosophy and his personal eminence as an intellectual leader of contemporary culture, one must dissociate philosophy almost completely from its academical status as a special study. Croce is not and has never been a university professor, and his philosophical writings have nothing whatever of the character of text-books. Philosophy is for him a perpetual human interest, manifesting itself in, and intrinsic to, every mental act. He expresses this by declaring the essential identity of philo-

sophy and history. Philosophy is the interpretation of history, and history is the expression of philosophy. All literary and historical criticism in his view depends on the complete understanding of the essential nature of human activity. Philosophy is therefore the light which irradiates all artistic production and all progress and decay of civilisation.

Croce's method in his philosophical writings is first to present his theory and then to trace the development of the idea by a critical examination of the history of philosophy. The book which probably gives the most direct insight into his principle and method is the essay entitled, 'What is Living and what is Dead in the Philosophy of Hegel.' For Croce, as for Hegel, mind or spirit is reality, and this reality is essentially active. What Croce criticises in the Hegelian system is its transcendentalism. For him the real world is that in which we effectively live. Reality is immanent in the world of ordinary experience, and never transcends it. There is consequently no difficulty in relating thought to being; the difficulty would be to conceive a thought detached from being or a being detached from thought. Hegel conceived a philosophy of history; Croce conceives philosophy as history. This means that history is not anecdotal, a chronicle of definite fixed and unalterable events, about which the only question is the accuracy of past records; on the contrary, it is the interpretation of what is, the actual present unfolding itself in our lives. All history, Croce declares, is present, not past.

Croce's conception of philosophy as the science of mind is an uncompromising idealism, but an entirely new form of idealism. It is not, like Berkeley's idealism or Kant's doctrine of the unknowability of noumena, primarily a theory of knowledge, nor is it the metaphysics of a transcendent reality. It is the science of mind, but a science which is not one of the sciences with its place in a hierarchy; it is science of reality in the ultimate meaning and universal comprehensiveness of the term.

The four volumes of the *Philosophy of Mind* present this science as the grades, or stages, of an unfolding activity. It is systematic in the sense in which all science is necessarily systematic, and yet there is no system in the sense of a logical structure dependent on fixity of categories and rigidity of forms. The fundamental distinction which presents itself when we analyse mind as essentially an activity is not the distinction between thought and thing, but the distinction between knowing and acting. Mind is both a theoretical and a practical activity. It is process. It never *is*; it is always *becoming*. Knowing and acting are grades or stages of this process, and their order is fixed and irreversible. Knowing is the condition of acting; acting is conditioned by knowing, and not *vice versa*. This is the ground on which materialism is rejected. Every form of materialism conceives the theoretical activity or knowing as posterior to and dependent upon the practical activity or acting. For materialism, what a thing does depends on what it is; for idealism, a thing is what it does.

Each of these two activities, the theoretical and the practical, has also its own grades or stages. It is in the distinction of the grades of the theoretical activity that Croce's æsthetic doctrine, his greatest philosophical innovation, is presented. Man has two faculties, a faculty of imagination and a faculty of reason. By the first he gives expression to his intuitions and produces images; by the second he relates those images and produces concepts. Imagination and thought, however, are not independent faculties; they are the two grades

or stages, or, rather, they are the twofold degree of man's activity in knowing. They correspond to the old division between sense and understanding, but instead of sense being conceived as a passive receptivity, it is conceived as æsthetic activity. All men are by nature first poets, then philosophers. Similarly Croce finds a twofold degree in the practical activity. All actions are primarily economic, and on this economic activity the ethical activity is dependent. Philosophy, therefore, is for Croce a methodology, that is, a way of studying reality, and not a science of a metaphysical reality transcending the physical sciences or defining their realm.

A few only of the historical and literary works have been translated. Croce has probably done more than any past or present writer to bring to light the character of the Italian intellectual contribution in the history and development of western culture. He has given new interest to the study of a long-neglected philosopher, Gianbattista Vico (1668-1744), a professor of rhetoric in the university of Naples. It was, he tells us, in the study of the *Nuova Scienza* of Vico that he discovered the original formulation of the æsthetic theory now associated with himself. Another great Italian writer nearer our own time whom Croce has made the subject of special study is the Neapolitan patriot, Francesco de Sanctis, the historian of Italian literature. Croce's studies, however, are not limited to the history and literature of his own country. The essay on 'Historical Materialism' deals with the economics of Karl Marx, and his literary criticisms include original studies of Goethe and of Shakespeare.

Croce's complete works are published by Laterza e Figli of Bari. The principal English translations are: by Douglas Ainslie, *Æsthetic, Logic, Philosophy of Practice, Theory of History, What is Living and what is Dead of the Philosophy of Hegel, Theory and History of Historiography, The Poetry of Dante*; by R. G. Collingwood, *The Philosophy of Vico*; by C. M. Meredith, *Historical Materialism and the Economics of Karl Marx*.

The works in English on the Philosophy of Croce are: *The Philosophy of Benedetto Croce*, by H. Wildon Carr; *Time and History, an Essay in the Proceedings of the British Academy*, by H. Wildon Carr; *Benedetto Croce, an Introduction to his Philosophy*, by Raffaello Piccoli.

**Crochet**, fancy work in worsted, cotton, or silk done by looping with a small hook.

**Crocidolite**, a mineral consisting of silicate of iron and sodium, in asbestos-like fibres, and sometimes called 'blue asbestos.' It may be regarded as a variety of riebeckite, one of the Amphibole (q. v.) group. It occurs in Griqualand, where it is often altered by oxidation and partial replacement by silica (quartz) into a hard, golden-yellow, fibrous mineral, with a silky chatoyant lustre, to which in South Africa the name crocidolite is extended. This quartz mineral is used for making ornaments.

**Crocker Land**, a supposed Arctic island, reported by Peary as sighted W. of Grant Land (1906). Mr Macmillan's expedition (1914) found it to be a mirage.

**Crockets** are ornaments used in Gothic architecture since the 12th century, when they were introduced on capitals of columns in the shape of incurved bunches of leaves springing from stems in place of the classic volutes employed before that date. Similar projecting crockets were soon applied to cornices, gables, spires, &c. In the Early English style they stand up in a detached manner, with the foliage at the point; but in the Decorated and Perpendicular styles the leaves are more developed and cling to the copes or ramps, to which they are applied as ornaments. Animal

forms, specially modified, are sometimes utilised for crockets. See the articles on the various styles.

**Crockett**, SAMUEL RUTHERFORD (1859-1914), novelist, born of farmer stock near New Galloway in Kirkcudbright, and educated at Castle Douglas and Edinburgh University, was in 1886-95 Free Church minister at Penicuik. He wrote a series of sketches, *The Stickit Minister*; a Galloway romance, *The Raiders* (1894); and much else.

**Crocodile** (*Crocodilus*), a large saurian reptile, the name being originally applied to the crocodile of the Nile only. The term is now used for a whole genus of reptiles, as well as for the small order (Crocodylia) to which it belongs. The order includes the largest living reptiles—viz. the crocodiles

Crocodile.

proper, the Alligators (q.v.), and Gavials (q.v.). The most distinctive characters are as follows:

**Externals.**—The body, which is provided with a long, laterally compressed, crested tail, is covered with horny scales and bony 'scutes,' the latter usually confined to the dorsal surface. There are four short, strong limbs, with five fingers and four toes, which are webbed in various degrees of completeness. The three inner digits bear claws. Glands with a musk-like secretion are found on the margin of the lower jaw, at the side of the cloacal aperture, and on the posterior margin of the dorsal shields. The musky odour is strongest during the breeding season. The nostrils lie close together at the point of the snout, and can be closed by valves; the eyes possess third eyelids, and the pupil is a vertical slit; the tympanum of the ear is overhung by a fold of skin which closes during diving; the cloaca has a longitudinal aperture.

**Skeleton.**—Between the skull and the hip-girdle there are always twenty-four vertebrae, and behind the sacrum a large and variable number of caudal pieces: The vertebrae are procelous—that is to say, hollow in front—and bear ribs in the neck as well as in the thoracic region. The ribs are provided with two heads for articulation with the vertebrae, and those in the middle of the thorax give off hook-like, backward-turned (uncinate) processes which also occur in Birds (q.v.). A breast-bone, with which the thoracic vertebrae are connected, is always present, and behind this a number of posterior rib-like processes ('abdominal ribs') form a further support. These arise from ossification of septa between the muscles. In the breast-girdle the clavicle is absent; the hip-girdle is normal. In the large skull the chief peculiarity is the formation of a closed bony palate. By the internal union of premaxillae, maxillae, palatines, and pterygoids, a median tunnel is formed, and the posterior aperture of the nostrils is thus shunted back to the very beginning of the trachea. The development of the skull has been studied by Parker. The mouth-opening is very large, and the jaws bear numerous, usually

conical, hollow teeth, implanted in distinct sockets, with reserve gems, at first on the inner side, and afterwards within the pulp cavities of the old ones.

The *nervous system* calls for no special remark. The peculiarities of nose, eye, and ear have been noted above. The animals have large lachrymal glands. The auditory passages communicate with the three Eustachian tubes (one median and two lateral), which have a single opening at the back of the mouth.

As regards the *alimentary system*, the flat tongue is fixed to the floor of the mouth, the mouth-cavity is bounded behind by two soft transverse membranes. These meet when the crocodile is drowning a victim, and prevent water rushing down the throat. The stomach is in several respects like that of birds. The *circulatory system* is of importance, since in crocodiles for the first time the heart is four-chambered (see CIRCULATION). The partition between the ventricles is here complete, but as two aortic arches remain, mixed blood still goes to the posterior body. The left aortic arch carries only venous blood to the viscera, whereas in other reptiles it carries mixed arterial and venous. The pulmonary arch carries purely venous, the right aortic arch purely arterial blood. The right and left aortic arches communicate at their roots just outside the heart by a small aperture—the *foramen Panizzae*. The *respiratory system* presents no special peculiarity except in the backward shunting of the internal opening of the nostrils. When drowning its prey, and with its half-shut mouth in consequence open to the water, the crocodile keeps the tip of its snout on the surface, the glottis is pushed a little forward to meet the posterior opening of the nostrils, a complete air channel is thus made, and respiration can go on unimpeded. The air is drawn into the lungs when the ribs expand, and an incipient diaphragm is also of use. The lungs are inclosed in pleural sacs. There is no urinary bladder.

**Mode of Life.**—Crocodiles are predominantly aquatic animals, and move rapidly by means of their powerful tail strokes. They are clumsy when ashore, and suffer from being stiff-necked. The body drags somewhat on the ground. They feed on fishes, especially in their youth, and on quadrupeds, which they catch by the river-side, and kill by drowning. If the prey cannot be readily torn, it is often buried till it begins to rot. For their shore work they prefer the darkness, but they also like to bask in the sun. They very often float in the water with their snout and upper back above the surface. The eggs, which are firm, though not thick-shelled, are laid in layers in holes on the banks. They are about the size of goose eggs, and the disproportion between the newly-hatched young and the adults is very striking. The females of some species are said to guard their young. Crocodiles are on the whole sluggish animals, and are very remarkable in the long continuance of the slow growth, which hardly seems to reach a limit as in other animals.

The crocodile has acquired in literature a character for deceitfulness which is largely undeserved. The conceit of 'crocodile's tears' (the animals have large lachrymal glands) was common in Shakespeare's time. Spenser describes (*Faerie Queene*, I. v. 18) the

Cruell craftie crocodile,  
Which, in false greefe hyding his harmefull guile,  
Doth weepe full sore, and sheddeth tender teares.

**Different Forms.**—The order of crocodiles includes twenty-five living species, distributed in three families and a doubtful number of genera. They are all found in tropical and warm regions. The three types may be thus contrasted:

Alligator	Crocodile	Gavial.
Nasal bones form part of nasal aperture.	As in alligator.	Do not.
Head short and broad.	Longer.	Very long.
Teeth very unequal. First and fourth lower teeth bite into upper pits.	Unequal. First into a pit, fourth into a groove.	Almost equal. First and fourth bite into grooves.
Union of lower jaws does not extend beyond fifth tooth.	Not beyond eighth.	At least to fourteenth.
Neck scutes distinct from back.	Sometimes distinct, sometimes united.	Continuous.
South America and south of North America.	Africa, India, North Australia, Cuba, South America	Ganges, Borneo, North Australia.

There are altogether a dozen different forms of Crocodile proper, some of which have been dignified as separate genera. The crocodile of the Nile (*C. vulgaris*) has almost disappeared from Egypt. There are very few below Wadi Halfa. Its range is from Egypt and from Senegal to the Cape. It is abundant in Madagascar. It is said sometimes to attain a length of 30 feet, though half that is considered large. It often fatally attacks man, and feeds very largely on smaller mammals. It grows very slowly and continuously, and, with the exception of man, has few formidable antagonists after it has survived its youth. Some two or three score of eggs, with delicate rough limy shells, about the size of those of geese, are laid in sandy cavities in the bank. The young crocodiles are often happily destroyed by the ichneumon, and by a species of lizard. The adult crocodile lives in amiable partnership with a little bird (*Pluvianus aegyptius*). As Herodotus relates, this watcher warns the crocodile by its cry when danger threatens, and it also cleans its body of small animals which fix themselves there. The crocodile was worshipped and even mummified by the ancient Egyptians, and it occasionally bore a part in the Roman gladiatorial combats. It is now hunted for the perfume of its musk-glands, and also for its skin and fat. Crocodile-hide has lately increased in value as an article of commerce. The eggs are esteemed as dainty morsels. The most widely distributed species is *C. bitorquatus*, or *porosus*. It occurs from the Mascarene to the Fiji Islands, from Farther India to Corea, and also on the north coast of Australia. It lives not only in fresh water, but ventures sometimes into the sea. A very large specimen at South Kensington measures 17½ feet in length. *C. frontatus*, in equatorial West Africa; *C. acutus*, in the north-west of South America, in Central America, and in the West Indies; *C. cataphractus* (often placed in a special genus, *Mecistops*), from the west coast of Africa, are other important species.

**History.**—These giant reptiles, like other large forms, have in recent ages been continuously on the wane. They date from the Triassic period (Belodon, Parasuchus, and Stagonolepis—the last from the Elgin sandstones). In the Jurassic age they are very numerous, forty species having been recorded from British strata alone. In the Chalk, the first Crocodilia with anteriorly concave vertebræ appear in contrast to the Triassic, the Jurassic, and in part the Cretaceous forms, which had biconcave vertebræ. Among these Cretaceous forms are true Crocodiles and Gavials, which are also abundant in Tertiary strata. Huxley worked out the 'almost unbroken' series of gradations from the ancient Triassic forms down to the modern crocodiles, but where this series takes origin among the ancient reptiles is still obscure.

See ALLIGATOR, GAVIAL, REPTILE; G. A. Boulenger, *Catalogue of Reptiles in the British Museum* (1889–1896); E. D. Cope, 'Crocodilians, &c. of North America,' *Report*

*U.S. Nat. Museum for 1898* (1900); Hans Gadow, 'Amphibia and Reptiles,' *Cambridge Natural History*, vol. viii. (1901); A. Strauch, 'Synopsis der lebenden Crocodiliden,' *Mém. Acad. St Petersburg*, x. (1866).

**Crocus**, a very beautiful genus of Iridaceæ, all palæarctic, and particularly abundant in the Mediterranean countries and Asia Minor. Crocuses have long been cultivated in flower-gardens, particularly *C. vernus*, the purple crocus, with its many violet, white, or striped varieties; and *C. luteus*, and other yellow species; all so welcome in early spring. The saffron crocus (*C. sativus*, see SAFFRON) and other species flower in autumn. These must not be confused with the meadow saffron, often called autumn crocus (Colchicum, q.v.), which is a liliaceous plant, from which the true crocuses can at once be distinguished by their inferior ovary, and three instead of six stamens. *Bulbocodium vernum* is a pretty spring flower, also much resembling crocus, but closely akin to colchicum. Two species of crocus occur wild in England, *C. nudiflorus* and *C. vernus*, but the latter at least is merely naturalised. The flowers of one or two species are fragrant. Owing to the shortening and thickening of the stem, the ovary is subterranean, hidden among the leaf-bores, but in ripening it grows out upon a long thin procumbent pedicel, and thus deposits its seed at a sufficient distance from the parent plant. The thickened axis is a Corm (q.v.). Spring Crocus (*Crocus vernus*). It is necessary frequently to take up crocuses and plant them anew, on account of the multiplication of the corms.

**Crocus** of ANTIMONY is the oxysulphide of Antimony (q.v.). Crocus of Mars is the finely divided red oxide of iron. See COLCOTHAR.

**Croesus**, the last king of Lydia, succeeded his father, Alyattes, in 560 B.C. He made the Greeks of Asia Minor his tributaries, and extended his kingdom eastward from the Ægean to the Halys. From his conquests, his mines, and the golden sand of the Pactolus, he accumulated so much treasure that his wealth has become a proverb. He gave himself up in his court at Sardis to a life of pleasure and sumptuous extravagance, deemed himself the happiest man in the world, and was displeased when Solon, on a visit to his court, told him that no man should be called happy till his death. He soon found how uncertain was a happiness such as his; for his beloved son Atys was killed while hunting, and there was left to him only one son, who was dumb; whilst in his war with Cyrus he was totally defeated, and, according to one story (which is highly improbable), himself made prisoner and condemned to be burned (546). At the funeral pyre, his repeated exclamation of 'O Solon!' struck the conqueror, who, when told the reason of it, spared his life and treated him with great kindness. As to his death, nothing is known.

**Croft**, WILLIAM, musician, born in Warwickshire in 1677, was a chorister in the Chapel Royal, of which he became joint-organist in 1704, and sole organist in 1707. In 1708 he succeeded his old teacher, Dr Blow (q.v.), as organist of Westminster

Spring Crocus (*Crocus vernus*).

Abbey and choirmaster of the Chapel Royal; and in 1713 he took the degree of Mus. Doc. at Oxford. From 1704 Croft wrote a number of anthems for state ceremonies and public thanksgivings, thirty of which appeared in two folio volumes in 1724; and it is by these that he is now chiefly remembered. He died in 1727.

**Crofter.** The term 'croft' is commonly used in Scotland to designate a small holding of arable or pasture land, other than garden ground; and the tenant of such a holding, who resides on the holding, is called a crofter.

Lord Napier and Ettrick, who presided over the royal commission appointed in 1883 to inquire into the conditions of the crofters in the Highlands and Islands of Scotland, writing with first-hand knowledge, described in this *Encyclopædia* the conditions obtaining at that date in the Highland counties as follows:—

'Crofters may be broadly divided into two classes: (1) Those who occupy arable land in separate tenancy, and mountain pasture in joint tenancy; (2) those who occupy land in separate tenancy only. The first class may be denominated "township crofters," the second "independent crofters." The township crofters are by far the more numerous class, so much so that the joint tenancy of pasture is a characteristic feature of crofting life. They are scattered over the whole surface of the Western Highlands and Islands, and over the whole of Sutherland. They are found in Caithness, Orkney, Shetland, and in the interior of Ross-shire and Inverness-shire, but less frequently on the eastern seaboard. The township crofters hold directly from the landlord, pay money rents, have had a preponderant share in the construction and maintenance of the buildings on the holding, and have been the authors of the greater part of the simple improvements on the holding and the township. They have preserved some marks of a primitive community in common rights and common obligations, and in the election of township officers who, by the custom of the estate, exert some authority in regulating the relations of the occupiers among themselves, and the relations between the occupiers and the landlord. The crofting township of the Highlands is a partial survival of a system of land tenure once common to the whole of Scotland and prevalent in other countries. It has in all times existed in direct relations with the chief or landlord, yet the greater number of extant township crofters are the descendants of sub-tenants to the tacksman of a former period, and were brought into immediate dependency from the proprietor in the 18th century. The township crofter has always been in the eyes of the law a tenant at will, whether holding under the landlord or the tacksman, except in the case of a specific covenant to the contrary, but it is probable that during the prevalence of the clan system the mutual interests and affections of chief, tacksmen, and people procured for the crofters the actual status of permanent tenure. While the crofters derive a material share of their livelihood and even of their food from the holding, their existence would be impossible without other sources of support. Among these fishing holds the first place, and often affords the chief means of subsistence; but other local employments, domestic crafts, itinerant rural labour in the south, the earnings of a seafaring life, and remittances from relatives at home and abroad, all contribute to the crofters' maintenance.

'The grievances from which the great mass of the township crofters have suffered may be enumerated as follows: The restricted area of holdings, and especially the reduction of common pasture land; high rents in exceptional cases; disturbance without due compensation; the molestation of deer and

other game; the imposition of excessive local rates; the increasing burden of cottar dependents; want of harbours and defective means of transport to the centres of consumption. . . .

'The independent crofters, who may be recognised as a distinct order among the crofting population, are found in all the Highland counties. They appear in considerable numbers in Argyllshire, in Caithness, in Orkney, in Shetland, and in the eastern parts of Inverness-shire and Ross-shire. They are more rare in Sutherland, on the western seaboard, and in the Hebrides. These laborious tenants have been recruited from the working-classes in adjacent districts, and from the members of broken townships dispersed by the formation of sheep farms. Established, for the most part, on waste lands under improving leases or stringent estate regulations, favoured in the eastern districts by a drier climate and soil, surrounded by the examples of a superior husbandry, and encouraged by assistance from the landlord, they have attained a higher condition than the crofting communities, both in regard to dwellings and tillage. The alleged grievances of the independent crofters have reference mainly to high rents, insecurity of tenure, and confiscation of improvements.

'In recording the diversities of crofting tenure it is necessary to mention the exceptional examples of freehold crofts with common pasture in the united parishes of Harray and Birsay in Orkney. These minute estates exhibit a marked superiority over yearly tenancies elsewhere. Belonging to a vigorous race of cultivators whose families prosecuted their fortunes in the colonies and on the sea, the Orkney freeholds have not suffered from excessive subdivision, and illustrate the advantages attached to stability and possession. . . .

'Closely associated with the crofters by origin, vocations, and distresses are the cottars. These people, who are most numerous in the Long Island, are occupiers of dwellings and small patches of ground, holding rarely from the landlord, more frequently from the farmer, the township, or the individual crofter, and are sometimes mere squatters, paying no rent and owing no allegiance. They exist by fishing, by casual employments on the land, and by public charity.'

By a series of statutes, commencing with the Crofters' Holdings Act, 1886, and culminating in the Small Landholders (Scotland) Act, 1911, and the Land Settlement (Scotland) Act, 1919, a new tenure for small holdings has now been established throughout Scotland.

The Crofters' Holdings Acts, 1886-91, applied only to such portions of the counties of Argyll, Inverness, Ross and Cromarty, Sutherland, Caithness, and Orkney and Shetland, as the Crofters Commission—a body of commissioners, three in number, appointed to administer these acts—might determine to be crofting parishes. In the result, all the parishes within the counties named, except two in Inverness, two in Ross and Cromarty, and eight in Argyll, were found to be crofting parishes. The term 'crofter' in the Crofters Acts meant any person who, at the passing of the Act of 1886, was a yearly tenant of a holding, at a rent not exceeding £30, in a crofting parish, who resided on his holding, and the successor of such a person in the holding, being his heir or a 'legatee,' i.e. a member of his family to whom he bequeathed his right to the holding. The crofter could not be removed except on his failure to fulfil certain statutory conditions, or on the landlord obtaining the sanction of the Crofters Commission to 'resume' the holding. The crofter was entitled, upon one year's notice in writing to the landlord, to renounce the tenancy. On renouncing, or being removed from, the holding he was given a right to receive compensation for permanent improvements, suitable to the holding,

executed or paid for by himself or his predecessors of the same family. Either the landlord or the crofter might apply to the commissioners to fix the 'fair rent' to be paid by the crofter, and the commissioners had power to reduce or extinguish any arrears of rent on any holding for which they were called on to fix a fair rent. The commissioners, on the application of five or more crofters resident on neighbouring holdings, were empowered, under certain conditions, to assign available land for the enlargement of the holdings of the crofter applicants. In addition, the commissioners had powers to allocate pasturage among crofters, to determine the boundaries of crofts and grazings, and to make orders with reference to fencing. Certain rights to compensation for permanent improvements were also conferred on 'cottars,' i.e. occupiers of dwelling-houses in a crofting parish, with or without land, who either paid no rent or were yearly tenants at a rent not exceeding £6. The Acts of 1891 and 1908 contained elaborate regulations with regard to the common grazings of townships.

It is scarcely disputed that the results accruing in the Highland counties from the operation of the Crofters Acts have in the main been highly beneficial and satisfactory. The Highlands and Islands Commission, commonly known as the Deer Forests Commission, reporting in 1895, described some of the more important results thus: '(1) The fixing of fair rent has to a large extent removed from the minds of the crofters the sense of hardship arising from the belief that they were made to pay rent on their own improvements, or otherwise made to pay at an excessive rate for soil of a poor quality. (2) The combination of a fair rent with statutory security of tenure has not only taken away or allayed causes of discontent, but has imparted a new spirit to crofters, and imbued them with fresh energy. . . . We found more attention is being paid to cultivation, to rotation of crops, to reclamation of out-runs, to fencing, and to the formation or repair of township roads; but most conspicuous of all the effects perceptible is that upon buildings, including both dwelling-houses and steadings. (3) The enlargement of holdings granted has been . . . of great benefit to the holdings enlarged. (4) The percentage of arrears cancelled has terminated liabilities which could never have been met.'

The anxiety caused by the decline of population in the rural districts of Scotland gave impetus to a movement to encourage the tenants of small holdings throughout Scotland by giving them security of tenure, and enabling them to have the rents of their holdings judicially fixed. The Small Landholders (Scotland) Act, 1911, sought to accomplish this object by in effect extending to the whole of Scotland the system of tenure which had been set up in the Highland counties by the Crofters Acts. Subject to certain special exceptions, all agricultural holdings in Scotland of a rent not exceeding £50, or of an area not exceeding 50 acres (exclusive of any common pasture or grazing), are within the scope of the act.

The act established a Land Court, to which were transferred all the powers and duties of the Crofters Commission. Three members form a quorum, but the court may delegate any of its powers to any one member, or to any two members, with or without the assistance of one or more land valuers, assessors, or other skilled persons. Any order or decision arrived at under such delegation is, however, subject to review by the full court. The court has the ordinary powers of a judicial tribunal to summon witnesses, to examine them on oath, to require the production of documents, to determine questions of law or fact, and to award expenses. An appeal by way of stated case upon a

question of law lies from the Land Court to the Court of Session.

The tenants of small holdings under the act fall into two classes: (1) Landholders and (2) statutory small tenants.

(1) The act transformed into landholders (a) all crofters under the Crofters Acts; and (b) all persons who, at the date of the act, were in possession, either from year to year or under a lease, of holdings within the above-mentioned limit of rent or area, provided that the greater part of the buildings and other permanent improvements had been made or paid for by the tenant or his predecessors in the same family. When such a tenant held under a lease at the date of the act, he becomes a landholder on the expiry of the lease.

The landholder has a permanent right to the occupation of his holding, subject to certain statutory conditions. The more important statutory conditions, on breach of which he can be removed, are that he pays the rent, does not cause dilapidation of the buildings or deterioration of the soil, does not subdivide or sublet the holding, or erect additional dwelling-houses thereon, without the landlord's consent, does not become bankrupt, and does not cease to cultivate the holding by himself or his family with or without hired labour. The rent of the holding, falling agreement, is fixed by the Land Court, and the 'fair rent,' so fixed, is subject to revision every seven years. The Land Court can deal with arrears of rent due by a landholder who has not had a fair rent previously fixed. The landholder may renounce his tenancy on giving one year's notice in writing to the landlord, and he may also be required to surrender it in whole or in part if the landlord obtains the sanction of the Land Court to 'resume' it, or part of it, for purposes specified in the act. On quitting, or being removed from, the holding the landholder is entitled to compensation for permanent improvements, suitable to the holding made by himself or his predecessors of the same family while under no written obligation to make them. In these and other respects, the tenure of the landholder is substantially similar to that of the crofter under the Crofters Acts. The landholder's right, in default of bequest, descends to his heir-at-law. He may bequeath his right; but, to prevent subdivision, the bequest must be to one person, and that person must be a 'member of his family.' By sect. 13 of the Land Settlement Act, 1919, the son-in-law of a landholder is now deemed to be a member of his family. He, unlike the Irish tenant, has no power at his own hand to sell or assign his right *inter vivos* without the landlord's consent; but, if he is unable to work his holding through illness or old age, he may obtain leave from the Land Court to assign his right to a member of his family.

(2) Persons who, at the date of the act, were in possession, either from year to year or under a lease, of holdings within the prescribed limits of rent or area, but who had not provided the greater part of the buildings or other permanent improvements, became, not landholders, but 'statutory small tenants.' Such tenants enjoy fixity of tenure and, in default of agreement, have the rents of their holdings fixed by the Land Court. The rent so fixed is to be 'an equitable rent,' i.e. the rent which a willing lessee would pay to a willing lessor, and it runs for such number of years as the Land Court may determine. On the expiry of that period the statutory small tenant is entitled to a renewal of his tenancy, unless the landlord satisfies the court that there is reasonable objection to such renewal. The Land Court has no power to deal with arrears of rent due by statutory small tenants. Since the passing of the act, it has become clear that most of the tenants in Scotland outside the

northern counties are not in the position of having made or paid for the greater part of the improvements on their holdings, and, therefore, belong to the class of statutory small tenants. Such tenants, however, may become landholders if it is found by the Land Court that the landlord has failed to maintain the buildings and permanent improvements required for the cultivation and reasonable equipment of the holding, in so far as the tenant is not under an obligation to do so.

The Act of 1911 also created a Scottish Board of Agriculture, consisting of three persons, charged with 'the general duty of promoting the interests of agriculture, forestry, and other rural industries in Scotland.' One of the chief duties of the board has relation to the creation and equipment of small holdings and the enlargement of holdings. A member of the board, who is designated the Commissioner for Small Holdings, has the duty of inquiring and reporting what demand exists for small holdings and of negotiating with landlords schemes for the registration by agreement of new holders. The conditions under which, failing agreement, land may be acquired for small holdings are now laid down in sect 9 of the Land Settlement Act, 1919. It is the duty of the board, when satisfied that there is a demand for small holdings and that suitable land is available, to prepare a scheme for the constitution of such holdings, showing the situation and area of the land, the number and areas of the new holdings, the rent of each new holding, the water-supply for each new holding, and the area of any common pasture to be occupied in connection with the new holdings. The prepared scheme is intimated to the landlord, tenant, and occupier of the land, who may make representations concerning the scheme to the board. The board, after giving to all persons interested an opportunity of being heard, may, with the consent of the Secretary for Scotland, make an order confirming the scheme, in whole or in part, and with or without modification, or may abandon the scheme. Compensation is payable to the landlord, tenant, and occupier of the land for any damage or injury done to him in consequence of, and directly attributable to, the constitution of new holdings under the scheme. The compensation, failing agreement, is determined, upon the application of either party, by the Land Court. The compensation does not include any compensation for injury done to or depreciation in the selling value of the land, or of the estate of which the land forms part, except in so far as arising from injury done to or depreciation in the letting value of the land or estate. Nor is compensation payable for injury done to the value of the sporting rights over the land or estate in so far as it exceeds the estimated value of such rights if the land or estate were put to the full reasonable use for which it could be let to ordinary agricultural or pastoral tenants. Any benefit or relief resulting to the landlord or other person from an enhancement of the letting value of the land or estate in consequence of the constitution of new holdings under the scheme is set against damage or injury done to him.

**Croisic**, LE, a fishing-port and watering-place, in the French department of Loire-Inférieure, 20 miles W. of St Nazaire; known from Browning's *Two Poets of Croisic*.

**Croker**, JOHN WILSON, politician and man of letters, was born at Galway, 20th December 1780, the son of the surveyor-general of customs and excise in Ireland. After four years at Trinity College, Dublin, in 1800 he entered Lincoln's Inn, but in 1802 was called to the Irish bar. Two satires on the Irish stage and on Dublin society (1804-5) proved brilliant hits; so did his *Sketch*

*of Ireland Past and Present* (1807), a pamphlet advocating Catholic emancipation. In 1809 he published a poem on the battle of Talavera, which Wellington pronounced 'entertaining,' and during the same year helped to found the *Quarterly*, to which up to 1854 he contributed 260 articles. He had entered parliament for Downpatrick in 1807; and now in 1809 he was rewarded with the lucrative post of Secretary of the Admiralty for his warm defence of the Duke of York, who was charged with conniving at and sharing in the sale of army commissions by his mistress. That post he held till 1830, and then retired with a pension of £1500 a year. On the passing of the Reform Bill (1832), he refused to re-enter parliament, unable 'spontaneously to take an active share in a system which must subvert the church, the peerage, and the throne—in one word, the constitution of England.' He would not even take office under Peel, his old friend (1834); and with Peel he broke utterly on the repeal of the Corn Laws (1846). He died 10th August 1857. Among the seventeen works that he wrote or edited were his *Stories for Children from English History* (1817), which suggested to Scott the *Tales of a Grandfather*; the *Suffolk Papers* (1823); his *Boswell's Johnson* (1831); and *Essays on the Early Period of the French Revolution* (1857). By some Croker is chiefly remembered for his onslaught on Keats, and Macaulay's onslaught on him (Macaulay 'detested him more than cold boiled veal'); or as the originator of the term Conservative (q.v.); a founder of the Athenæum Club, and the 'Rigby' of Disraeli's *Coningsby*—the jackal of 'Lord Monmouth' (the Marquis of Hertford). But in Sir Theodore Martin's nine-page eulogy in the *Dictionary of National Biography* (vol. xiii. 1888), he figures as a 'debater of the first rank,' a master of 'rhetoric that eclipsed Macaulay's,' the 'friend and confidant of many of the best and ablest men of his time,' a pattern of 'sincerity,' 'consistency,' 'devoted loyalty and unselfishness.' See also his *Memoirs, Diaries, and Correspondence*, edited by Louis J. Jennings (3 vols. 1884).

**Croker**, THOMAS CROFTON, Irish folklorist, was born at Cork, 15th January 1798, and in 1814 was apprenticed to a Quaker merchant, but four years later got a clerkship in the Admiralty through John Wilson Croker, a friend, though no relation, of his father's. He retained this post till 1850, and died at Old Brompton, 8th August 1854. As a boy of fourteen he had begun to collect songs and legends of the Irish peasantry; in 1818 he sent Moore nearly forty old Irish melodies; and in 1825 published anonymously his *Fairy Legends and Traditions of the South of Ireland*, a work which charmed Scott, and was translated into German by the brothers Grimm (1826). A second series followed in 1827, and the whole reached a 6th edition in 1882. Of nearly twenty more works of which Croker was either the author or editor, the best were *Researches in the South of Ireland* (1824); *Legends of the Lakes* (1829), illustrated by his friend Maclise, and re-issued as *Killarney Legends* (1876); *The Adventures of Barney Mahoney* (1832); *A Memoir of Joseph Holt, General of the Irish Rebels* (1837); and *Popular Songs of Ireland* (1839; new ed. by Professor H. Morley, 1885). Croker was a zealous antiquary, a member of many learned societies. See the Life by his son, prefixed to the 1839 edition of the *Fairy Legends*.

**Croll**, JAMES, physicist, was born in 1821 near Coupar-Angus, in Perthshire. He received an elementary school-education, but in science was wholly self-trained. Successively millwright, insurance-agent, and janitor of the museum of Anderson's College, Glasgow, in 1867 he joined the staff of the

Geological Survey of Scotland, but retired in 1881. An F.R.S. and LL.D. since 1876, he died 15th December 1890 (see his Life by J. C. Irons, 1896). Besides many papers in the scientific journals, he wrote *The Philosophy of Theism* (1857), *Climate and Time* (1875), *Discussions on Climate and Cosmology* (1886), and *Stellar Evolution* (1889). *Climate and Time*, one of the most important contributions to geological climatology, worked out in detail the view with which Croll's name is identified, that, contrary to the opinion of most physicists, changes of the earth's climate, such as the glacial periods, are due to the secular variations in the eccentricity of the earth's orbit, together with consequences arising out of them, such as the deflection of ocean currents. See CLIMATE, PLEISTOCENE SYSTEM, PRECESSION.

**Croly**, GEORGE, poet, romance-writer, biographer, and preacher, was born at Dublin in 1780, and educated at Trinity College there. He took orders in 1804, and in 1810 came to London, where, after twenty-four years of literary labour, he in 1835 became rector of St Stephen's, Walbrook. He died 24th November 1860. Between 1817 and 1858 Dr Croly published some forty works—the best known being the romance of *Salathiel*.

**Crô-Magnon**. See ANTHROPOLOGY, STONE AGE.

**Cromarty**, formerly the county town of Cromartyshire, on the southern shore of the Cromarty Firth, 2 miles from its entrance, and 19 NNE. of Inverness; since 1912, when the erection of defences was begun, it has been an important naval depot. From the famous Sir Thomas Uquhart (q.v.) the estate came to the second son of that Sir George Mackenzie who in 1685 was created Viscount Tarbat, and in 1703 Earl of Cromarty—a title forfeited by the third earl for his share in the '45, but revived (1861) in favour of his descendant, the Duchess of Sutherland, from whom it passed to her second son (1888) and his daughter (1895). In 1859 a statue was erected of Hugh Miller (q.v.), whose birth-house is now a geological museum. With Wick and four other burghs Cromarty returned one member to parliament until 1918. Pop. 1000.—CROMARTY FIRTH, a land-locked inlet on the north-east coast of Scotland, extends 19½ miles north-eastward and eastward to the Moay Firth, and is enclosed by the county of Ross and Cromarty. It forms a noble harbour, 1 mile to 7½ miles broad, and 5 to 35 fathoms deep; receives at its head the Conon; and narrows at its entrance to 7 furlongs, between the beetling North and South Sutors, 400 and 463 feet high. On its shores are the towns of Dingwall, Invergordon, and Cromarty (each of which has a ferry), and some villages; the Old Red Sandstone near its mouth is classic as Hugh Miller's hunting-ground.—CROMARTYSHIRE, once a Scottish county, 369 sq. m. in area, consisting of ten detached portions scattered up and down Ross-shire (q.v.), with which it was incorporated by the Local Government Act of 1889. It comprised the ancient sheriffdom of Cromarty, and outlying bits annexed thereto towards the close of the 17th century at the instigation of Viscount Tarbat, who wished thus to hold jurisdiction over every part of his estates.—See Sir W. Fraser's *Earls of Cromarty* (2 vols. 1876).

**Cromdale**, a place in Elginshire, on the right bank of the Spey, 5 miles NE. of Grantown. Here, on 1st May 1690, 800 Jacobite Highlanders were surprised and routed by a body of King William's dragoons. This encounter is celebrated in a song called *The Haughs of Cromdale*.

**Crome**, JOHN (known as 'Old Crome'), landscape-painter, the chief member of the 'Norwich School' of artists, was born in that city, the son

of a poor weaver, 22d December 1768. After serving as an errand-boy to a physician, he was apprenticed to a house-painter; but, showing a strong predilection for art, he was befriended by T. Harvey, of Catton, who procured him employment as a drawing-master, and permitted him to study works by Gainsborough and the Dutch masters in his collection. He also received some instruction from Beechey and Opie. He was mainly influential in founding, in 1803, the Norwich Society of Artists, which held exhibitions from 1805, and of which he was president in 1808. He occasionally visited London, where he exhibited in the Academy and the British Institution; and a tour through Belgium and France in 1814 resulted in 'The Fishmarket on the Beach, Boulogne,' and 'The Boulevard des Italiens, Paris.' But his subjects were nearly always derived from the scenery of his native county, which, though founding his practice upon that of the Dutch landscapists, he treated in a singularly direct and individual fashion, painting trees, and especially the oak, with exceptional fidelity and beauty. His works realised only most moderate prices during the artist's life; but he is now recognised as one of the great names among English landscapists, and fine examples of his art fetch very large sums. Several of his oil-paintings, including the great 'Mousehold Heath,' are in the National Gallery; and among his other masterpieces may be mentioned 'Carrow Abbey,' 'Chapel Fields, Norwich,' 'Oak at Porlingland,' and 'The Willow.' His water-colours are rare; his etchings of Norfolk scenery were published in 1834. He died 22d April 1821, and was buried in the church of St George, Colegate. The centenary of his death was commemorated in Norwich by a fine loan exhibition at the Castle Museum. His eldest son, John Berney Crome (1794-1842), painted landscapes after the style of his father.

See Sir F. Wedmore's *Studies in English Art* (1876); L. Binyon's *Crome and Cotman* (1897); T. Cole and J. C. van Dyke's *Old English Masters* (1902); W. F. Dickes's *Norwich School of Painting* (1906); H. S. Theobald's *Crome's Etchings, with some Account of his Paintings* (1906); H. M. Cundall's *Norwich School* (1920); C. H. C. Baker, *Crome* (1921); G. A. Stephen's *Norfolk Artists*, a bibliography (1915).

**Cromer**, a fashionable and delightful watering-place on the coast of Norfolk, 23 miles N. of Norwich. The sea has here made great encroachments on the cliffs since 1350, though the town itself is now protected by a sea-wall, formed in 1877, with an esplanade and a pier. There are capital sands and golf-links (1887), and the church has a noble flint-work tower of 160 feet. Pop. 5400. It gave an earl's title to Sir Evelyn Baring (q.v.).

**Cromer Forest Bed**. See PLEISTOCENE.

**Cromlech** (from the Gaelic *crom*, 'curved,' and *leac*, 'a stone') is a modern term, formerly applied by British archaeologists to a class of megalithic monuments, consisting of one flat stone supported on two or more upright stones, and forming a kind of open chamber with a roof. It is now generally recognised, however, that these are merely the denuded or uncovered chambers of chambered Cairns (q.v.) or Barrows (q.v.), for which another modern term, 'dolmen,' is now generally substituted (see DOLMEN). The French archaeologists retain the use of the word cromlech, but they have always applied it to those groups of standing stones which in Britain and Scandinavia are called Stone Circles (q.v.).

**Crompton**, SAMUEL, whose invention of the spinning-mule entitles him to rank as one of mankind's greatest benefactors, was born, the son, of a small farmer, at Firwood, near Bolton, Lanca-

shire, December 3, 1753. Like his father, Crompton was brought up to the loom and the farm. His mother, a woman of great energy, perseverance, and stern independence, when left a widow struggled hard to give him and her two daughters the best education the district afforded. When he was old enough, he assisted her in the farm, and wove, and earned a little money by playing the violin at Bolton theatre. At the age of twenty-one, he was so much annoyed at the breaking ends of yarn and the difficulties in getting it to weave that he set to work to invent a spinning-machine which should produce better yarn than Hargreaves', one of which his mother possessed. For five years he laboured to realise his idea, sitting up late at night to overcome the successive difficulties, and resuming his labour for daily bread early in the morning. In 1779 he succeeded in framing a machine which produced yarn of such astonishing fineness that the house was beset by persons eager to know the secret. He was rendered miserable. All kinds of devices were tried to gain admission; even ladders were placed against the windows. His machine was such that if a mechanic saw it, he could carry away the leading features of it. He could not leave the house for fear of his discovery being stolen from him. He had spent every farthing he had in the world upon its completion; he had no funds wherewith to obtain a patent, and his shy and unbusiness-like temperament prevented him profiting as he should have done by his invention. A Bolton manufacturer persuaded him to disclose the invention to the trade, under the promise of a liberal subscription, but all that he got was £87, 6s. 6d. Soured by this treatment, in the course of time he saved money enough to begin manufacturing on a small scale at Oldhams, near Bolton, and latterly at Bolton, but not till his rivals had a hopeless start of him in the business. After the use of the mule had told distinctly on British manufacturing prosperity, a sum of between £400 and £500 was raised for him by subscription through John Kennedy, his earliest biographer. Efforts were made to procure for him a national reward. Five thousand pounds was all he obtained in 1812, and he returned to Bolton almost broken-hearted. He began the bleaching trade at Over Darwen, then became a partner in a cotton firm, but was unsuccessful in both. Some friends latterly purchased an annuity of £63 for him. He died June 26, 1827. Crompton's was soon by far the most used of all spinning-machines, and in 1811 the number of spindles on his principle was 4,600,000, while there were only 310,516 of Arkwright's, and 155,880 of Hargreaves'. A monument was placed over his grave, and in 1862 a bronze statue of him erected at Bolton. See Kennedy's *Memoir* in vol. v. of *Memoirs of Literary and Philosophical Society of Manchester*, and French's *Life of Crompton* (1860).

**Cromwell, OLIVER**, Protector of the Commonwealth of England, Scotland, and Ireland, was born at Huntingdon, April 25, 1599. He was the son of Robert Cromwell, younger son of Sir Henry Cromwell, descendant of a nephew of Cromwell, Earl of Essex, and was a younger brother of Sir Henry Cromwell of Hinchinbrook. His mother was Elizabeth, daughter of Thomas Steward of Ely, afterwards knighted by James I., who, when she married Robert Cromwell, was the widow of William Lynne. He was first-cousin to John Hampden. He was educated at Huntingdon grammar-school, the master of which was the Puritan Dr Beard, and at Sydney-Sussex College, Cambridge, and seems to have carried away a modest share of classical and general culture. He went to London to study law, but never

entered an Inn of Court. In June 1617 his father died, leaving him a moderate estate at Huntingdon. In August 1620 he married Elizabeth, daughter of Sir James Bouchier, a London merchant. Of the wildness of his youth there is no proof beyond his own remorseful confession after his conversion that before he knew God he had been the chief of sinners. He was, however, under medical treatment for hypochondria. He embraced Puritanism in its most enthusiastic form, attended and supported the ministry of its proscribed preachers, and became a zealous adherent of the cause, and opponent of its arch-enemy and persecutor Laud.

In 1628 he sat as member for Huntingdon in the stormy third parliament of Charles, and raised his voice against Romanising ecclesiastics. The parliament dissolved, he returned to farming at Huntingdon, whence he removed to St Ives and afterwards to Ely, where property had been left him by his uncle. He appears to have come into collision as a local patriot with the king's commissioners for the drainage of the Fens. He sat for Cambridge in the Short Parliament and in the Long Parliament (1640). In the Long Parliament, though no speaker, he was active and vehement on the Puritan side. Sir Philip Warwick describes him at this period in 'a plain cloth suit, which seemed to have been made by an ill country tailor; his linen was plain, and not very clean; and I remember a speck or two of blood upon his little band, which was not much larger than his collar. His hat was without a hat-band; his stature was of a good size; his sword stuck close to his side; his countenance swollen and reddish; his voice sharp and untunable; and his eloquence full of fervour.' Sir Philip adds: 'It lessened much my reverence unto that great council, for this gentleman was very much hearkened unto.'

When war broke out (1642) he was sent down to organise his district for the parliament, which he did with the greatest vigour and success. He also subscribed £500 to the cause. Becoming captain of a troop of parliamentary horse, he fought at Edgehill. After Edgehill, he warned his friends that the parliament must have soldiers of a better stamp, and that to the spirit of a chivalrous gentry must be opposed that of a God-fearing yeomanry. On this principle he formed his unconquerable Ironsides. With strict morality and organised enthusiasm he combined in the famous corps a rigid discipline, which enabled him always to keep his troopers well in hand, and thus to turn the wavering tide of more than one battle. While the cause of the parliament was depressed elsewhere, his constancy, capacity, and courage upheld it in the eastern counties, which had formed themselves into an association, of which he was the soul. A brilliant action near Gainsborough marked him for high command. In the summer of 1644 he, under Manchester, led the forces of the associated counties to join the Scots and the troops of the Fairfaxes before York, and in the battle of Marston Moor the charges of his cavalry decided the day. He now stood forth as the leader of the Independent and thoroughgoing party against the Presbyterians and moderates. After the second battle of Newbury he impeached the conduct of Manchester in parliament. While the Presbyterian and aristocratic generals were set aside by the Self-denying Ordinance, Cromwell was retained in command. Under Fairfax he led the new model army, of which he no doubt was the chief organiser, to decisive victory at Naseby, June 14, 1645. Fairfax being no politician, Cromwell became the representative of the army in its contest with the Presbyterian parliament, which desired to disband it. The Presbyterians proving intractable,

he resorted as usual to strong measures, marched on London, and coerced the parliament. He was never revolutionary, but he cared not for forms when they stood in the way of what he thought right. It was no doubt under his directions that Joyce carried off the king from Holmby. It seems that Cromwell desired, had it been possible, to make terms with the king; but Charles was incurably possessed with the idea of recovering his power by playing off one party against the other. Whether it was by Cromwell or by the Scotch envoys that Charles was induced to fly from Hampton Court is a question on which authorities differ.

As a prisoner in the Isle of Wight, the king, while he was negotiating with the parliament, was carrying on intrigues with his partisans in England and Scotland, which brought on the second Civil War and the invasion of England by Hamilton. Again Cromwell was called to take the field for his cause, which was once more in extreme peril. After swiftly quelling the insurrection in Wales, he marched northwards, attacked the invading army of Hamilton at Preston and totally destroyed it. The soldiery now clamoured for justice on the king; and Cromwell, probably sharing their wrath and despairing of any arrangement with the faithless Charles, complied with their demand, brought the king to trial, sat in the High Court of Justice, and signed the death-warrant (January 1649). Had ambition been his motive for this deed we should hardly have found him at the same time treating for the marriage of Richard, his heir, with the daughter of Mr Mayor, a private gentleman. The Commonwealth having been established, the first service rendered by Cromwell to it was the suppression of the formidable meeting of the Levellers, which he accomplished by a characteristic union of vigour with mercy. He was next sent to Ireland to end the civil war still raging there. This he did effectually, and on the whole humanely, though it cost some strokes of sanguinary severity, the necessity for which he himself deplored.

On his return from Ireland he (Fairfax having declined) took the command against the Scots, who had declared against the regicide republic and called in Charles II. With his usual daring he assumed the offensive and invaded Scotland. But he was out-generalled by Leslie, and was in extreme peril, when a false move of the Scots, by affording him battle, enabled him once more to display the superiority of the soldiery which he had trained and to win the decisive victory of Dunbar. The image of militant Puritanism was never more vividly presented than by Cromwell's bearing on that scene. With the defeated Covenanters he dealt as with estranged friends. The royalists proper, who still held the field in Scotland, having eluded his strategy and marched into England, he followed, and on September 3, 1651, at Worcester, gained the victory which he called his crowning mercy and which ended the Civil War. Returning to London in triumph, he declared for a constitutional settlement and an amnesty. The parliament, now reduced by revolutionary expulsions to the 'Rump,' was bent on perpetuating its own power. After fruitless negotiations Cromwell turned it out with unwise violence and contumely. Supreme power being now in his hands and those of the other chiefs of the army, he called the convention of Puritan notables, nicknamed the Barebones Parliament, for the settlement of the nation. The Barebones Parliament proving too visionary and revolutionary, was dismissed, and supreme power reverted to Cromwell and his officers.

Cromwell was now declared Protector under the instrument of government, which provided for a government by a single person with one House of

parliament elected on a reformed basis of representation, and a Council of State, in the appointment of which nomination by the Protector was combined with election by the parliament (December 16, 1653). A power of legislating by ordinance till parliament should meet was reserved to the Protector, and was largely used by Cromwell for the purposes of reorganisation and reform. His aim evidently was to restore in substance the ancient constitution of the realm, with a Protestant protectorate or monarchy, and full securities for liberty, especially for the religious liberty which had been in his mind at least the main object of the Civil War. But when parliament met, though elected under his writs, it fell to questioning his authority, and he was compelled to exclude the disaffected by a test. His second parliament, from which the recalcitrants were excluded at the outset, offered him the title of king. Cromwell wavered; but the stubborn resistance of the republican soldiers decided him to decline the offer. The Upper House of parliament was, however, restored, and the Protector was empowered to name his successor. A fixed revenue was also voted to him. He was now installed as Protector with a ceremonial resembling a coronation. When the parliament met again, its two Houses fell into a collision which compelled Cromwell to dissolve it; and his power thenceforth rested upon the army, though it was his constant desire to revert to constitutional government, and he was preparing to call a new parliament when he died.

His protectorate was a perpetual conflict with republican resistance on the one hand and with royalist plots and risings on the other, while his life was constantly threatened by royalist assassins. To keep down the royalists he for a time put the country under major-generals, supplying his treasury at the same time by an impost on the property of the cavaliers. He was, nevertheless, able to inaugurate a great policy, home and foreign. He reorganised the national church on the principle of comprehension, including all but Papists, Prelatists, and Antitrinitarians, while the ministry was weeded by commission, the result being, as Baxter, an opponent of the government, testifies, a ministry very acceptable to the people. Personally tolerant, Cromwell upheld toleration as far as he could, especially in the case of the Sectaries, and curbed the persecuting tendencies of parliament. For law reform he did his best, but professional interests were too strong for him. He united Scotland and Ireland to England, giving them both representation in parliament. Scotland, having free trade with England, enjoyed great prosperity under his rule. Ireland he sought to make a second England in order and industry, and if his measures were high-handed it must be remembered that the native Irish were then in an almost savage state. It was his aim to enlist ability, without distinction of party, and youths of promise from the universities into the service of the state. He saved the universities from the fanatics, put good men at their head, and encouraged letters.

But it is his foreign policy that has brought him most renown. Under him the Commonwealth became the head and protectress of Protestant Europe. He made peace with Holland and tried to form a league of all the Protestant states. He protected the Waldenses of Piedmont against their persecutors, using the pen of Milton in his protest. In the interest at once of religious liberty and commerce he allied himself with France, as the more liberal power, against Spain, the power of persecuting Roman Catholicism and the tyrant of the Western waters. He failed in an attempt on Hispaniola, but took Jamaica, and thus gave British enterprise a foothold in those seas. The

victories gained by his fleet under Blake over the Spaniards brought him at once glory and treasure. His troops, with those of France, won the battle of the Dunes, and he obtained Dunkirk as his share of the spoil. He sedulously fostered British commerce, and by the hand of Blake chastised the pirate-states of Barbary. His boast that he would make the name of Englishman as respected as that of Roman had been, was, so long as he reigned, fulfilled; and his bitterest enemies could not deny the impression which he had made on the world, or the height to which he had raised his country. His court was simple and frugal, yet dignified; and though there was a strain of coarseness in his character (as illustrated in occasional horseplay), his bearing in public upheld the majesty of the state.

Cromwell had always been a most loving husband and father, and the palace of the Protector was a virtuous English home. His speeches are very rough and unmethodical as compositions, but they are marked by sense, force, and intensity of purpose. He was fond of music, and not without regard for art. It seems that his government was striking root, since people of rank were beginning to ally themselves with it, and his heir succeeded without the slightest opposition. But disease and care, together with grief at the death of his favourite daughter, Lady Claypole, cut short his life. He died September 3, 1658, and the fabric of government which his mighty arm had sustained fell speedily to the ground.

The records of Cromwell's life are very imperfect. Of his greatness as a soldier and statesman there can be no question, but it is difficult across two centuries and a half to see into his heart and pronounce how far ambition mingled with higher motives. That the religious enthusiasm which sent him out to expose his life in war at the age of forty-three was sincere cannot be doubted; but religious enthusiasm is often associated with fanaticism and self-deception. One who knew Cromwell well has described him as 'in body compact and strong, about five feet ten in height, with a head which you might see was a vast treasury of natural parts, with a temper exceeding fiery but under strong moral restraint, and compassionate even to an effeminate measure.' 'A larger soul, I think, hath seldom dwelt in a house of clay than his was.' He was laid with great pomp in the tomb of the kings at Westminster, but after the Restoration his body was exposed on the gibbet at Tyburn and afterwards buried under it.

**Cromwell, RICHARD**, third son of Oliver, born October 4, 1626, became his father's heir by the death of his elder brothers, Robert and Oliver. An amiable but weak man, he lived at first in comparative privacy, but when the Protector had been empowered to nominate his successor, Richard was brought to the front, and an effort was made to train him to the work of government, but in vain. Scarcely had he entered on his office, when the forces of anarchy, both parliamentary and military, broke loose, and he found himself utterly unable to restrain them. It was probably with little reluctance that he quitted Whitehall and retired into

private life. After the Restoration he lived for a time abroad under a feigned name; but he returned to England about 1680, and passed the remainder of his life at Cheshunt, where he died July 12, 1712, and was buried in the church at Hursley, Hampshire.

**Cromwell, THOMAS** (*malleus monachorum*, 'the hammer of the monks'), was born about 1485, the son of a Putney blacksmith, cloth-shearer, brewer, and innkeeper. His youth was turbulent and adventurous. During eight or nine years passed on the Continent (1504-12), he seems to have served as a common soldier, to have been befriended at Florence by Frescobaldi the banker, to have acted as clerk at Antwerp and to a Venetian merchant, to have visited Rome, and to have traded on his own account at Middelburg. Anyhow, by 1513 he was back in England and married; there, step by step, he rose to wealth and importance as a wool-stapler and a scrivener, half usurer, half lawyer, having originally been bred to the law. Wolsey employed him as early as 1514; through Wolsey, probably, he got into parliament (1523); he was Wolsey's chief agent in the unpopular work of suppressing certain smaller monasteries for the endowment of his colleges at Ipswich and Oxford (1525); and finally he became his factotum and secretary. He stepped to greatness over his fallen master. Cavendish tells how on All-Hallows Day, 1529, he found 'Master Cromwell saying of Our Lady matins—which had been since a very strange sight in him'—and bewailing his own misadventure, but intending to ride from Esher to the court, 'where,' quoth he, 'I will either make or mar.' And Pole tells how, a few months earlier, Cromwell bade him take Machiavelli for his guide. Both stories illustrate the very man.

He was cheaply faithful to the cardinal, aiding him not only by quick-witted advice, and by pleading his cause in parliament, but even with £5 out of his own savings. Withal, he made himself friends of Wolsey's enemies; and his fidelity ingratiated him with Henry VIII. Him Cromwell promised to make the richest king ever in England, and counselled him to cut the knot of the divorce by declaring himself supreme head of the church. Counsel and promise were carried into effect by the Act of Supremacy (1534) and by the dissolution of the monasteries (1536-39). To abolish papal authority, break the power of the church, humble the nobility, and make the king absolute, were Cromwell's aims; in their accomplishment he stuck at nothing. At heart, it would seem, still a Catholic—for so late as 1535 he bequeathed £46 for a priest to sing mass for his soul—he yet did his utmost to Protestantise the English Church, whose 'polity,' in the words of Mr Froude, Cromwell's admirer, 'remains as it was left by its creator.' It is often hard to determine whether he was tool or instigator, to disserve his actions from those of Henry; both must be treated under Henry's reign. But here may be noticed his winning manners and ungraceful person, his venality and profusion, his purposeful ruthlessness and ubiquitous industry, his army of spies and vast correspondence—above all, the fact that that English 'Terror,' in which perished More and Fisher and hundreds of lowlier victims, set in with Cromwell's rise, and ebbed with Cromwell's fall. Among the posts and honours showered on him were those of privy-councillor (1531), chancellor of the exchequer (1533), secretary of state and master of the rolls (1534), vicar-general (1535), lord privy seal and Baron Cromwell of Oakham (1536), knight of the Garter and dean of Wells (1537), lord great chamberlain (1539), and finally, on 17th April 1540, Earl of Essex. 'He had,' says Professor Brewer, 'engrossed in his own hands powers such as no subject and no sovereign in this country had ever

possessed before or will ever possess again.' But the hand that had so exalted could equally abase him. The hatred all men bore him, the Catholic reaction, and Henry's aversion to Anne of Cleves, the coarse Lutheran consort of Cromwell's choosing, combined to effect his ruin: less than eight weeks after his elevation to the earldom he was arrested and lodged in the Tower. His abject entreaties for 'Mercy, mercy!' availed him nothing; as little did his filthy revelations of Henry's discourse with him touching Anne of Cleves. Condemned under a bill of attainder, his own favourite engine of tyranny, he was bunglingly beheaded on Tower Hill, 28th July 1540. See Gairdner's article in the *Dictionary of National Biography* (vol. xiii. 1888); Dean Hook's *Lives of the Archbishops of Canterbury* (vol. vi. chap. 1, 1868), Professor Biewer's article on 'The Royal Supremacy' in *English Studies* (1881); works cited under HENRY VIII.; and his *Life and Letters* by R. B. Merriman (1902).

**Cronje**, PIET, a Transvaal general, born in 1835, who took a leading part in the wars with Britain in 1881 and in 1899-1900. After a skilful and determined resistance to Lord Methuen at Magersfontein, he surrendered with 4000 of his army to Lord Roberts on the Modder River on 27th February 1900. A prisoner at St Helena till the peace, he subsequently visited the United States. He died in 1911.

**Cronstadt**, a Russian fortress and seaport, 20 miles W. of Petrograd, on a narrow island 7 miles long, at the mouth of the Neva. Cronstadt, though ice-bound from December to May, is at once a great naval station and the chief commercial port of Petrograd. It was founded by Peter the Great in 1710, after taking the island from the Swedes (1703). Its fortifications, all built of granite, command every approach to Petrograd. The place was considered impregnable by Sir Charles Napier, who reconnoitred it during the Russian war of 1854-55, but though subsequently strongly refortified, its defences, on the outbreak of the Great War, were altogether antiquated. Cronstadt, which is the seat of the Russian Admiralty, has three harbours: the east, intended for vessels of war; the middle harbour, where vessels are fitted up and repaired, and which is connected with the former by a broad canal; and the west or Merchant's Harbour, for the merchant-shipping. Since 1884 Petrograd is connected with Cronstadt by a ship-canal 200 feet wide and 22 feet deep. Cronstadt contains a cathedral and a statue of Peter the Great. It was seized by mutineers in 1921, but soon fell. Pop. 62,300.

**Cronstadt**, or BRASOV, in Transylvania. See KRONSTADT.

**Cronus**. See SATURN.

**Crook**, GEORGE, American soldier, born in Ohio in 1823, graduated at West Point in 1852, served in California till 1861, and was actively engaged throughout the civil war, in which he rose to the rank of major-general. He served against the Indians in Idaho (1866-72), in Arizona (1872-75), and crushed the great rising in Wyoming and Montana in 1876-77. In 1882 he returned to Arizona, where he controlled the Indians on the southern frontier, putting an end to the truck system. He died 21st March 1890.

**Crooked Island**. See BAHAMAS.

**Crookes**, SIR WILLIAM, K.C.B., O.M. (1832-1919), a great physicist and chemist, born in London, was a pupil and assistant of Hofmann at the Royal College of Chemistry, next superintended the meteorological department of the Radcliffe Observatory, and lectured on chemistry at the Science College,

Chester. In 1859 he founded the *Chemical News*, and in 1864 became also editor of the *Quarterly Journal of Science*. He was elected F.R.S. in 1863, vice-president of the Chemical Society in 1876, member of council of the Royal Society the year after, and in 1880 was awarded by the French *Académie des Sciences* an extraordinary prize of 3000 francs and a gold medal. He was an authority of the first rank on sanitary questions, especially the disposal of the sewage of towns, and his method of producing extreme vacua gave a great impulse to incandescent electric lighting. His original researches in chemistry and physics led to the discovery of the metal thallium in 1861, of the sodium amalgamation process for separating gold and silver from their ores in 1865, and of important discoveries in molecular physics and radiant matter, besides the invention of the Radiometer (q.v.). He wrote *Select Methods of Chemical Analysis* (1871), *The Wheat Problem* (revised 1918), and works on beet-sugar, dyeing, calico-printing, and sewage, and translated books on chemistry and metallurgy. 'Crookes Tubes' are Vacuum Tubes (q.v.); and see RÖNTGEN, GAS. For his spiritualistic views, see SPIRITUALISM. Crookes was president of the British Association in 1898. See *Life* by Fournier d'Albe (1923).

**Crookhaven**, a fishing village of County Cork, 30 miles SW. of Skibbereen, on a fine bay.

**Cropredy Bridge**, near Banbury, gives name to a royalist success (29th June 1644).

**Croquet**, an open-air game, in which two or more players endeavour to drive wooden balls, by means of long-handled mallets, through a series of arches set in the ground according to some pattern. The object of each player is to make the complete circle of six to ten hoops or arches; but during the course of the game he may have the progress of his ball retarded by his opponents, or assisted by his partners; and these friendly aids and hostile attacks constitute the chief interest of croquet. The game seems to be substantially a revival of the old game of Pall Mall, which gave its name to what is now the well-known London street, and to other places in England. Pall Mall, played with ball (Ital. *palla*) and mallet (Ital. *maglia*), came from France into England early in the 17th century, and died out in the 18th. Croquet (Fr. *croquer*, 'to crack') became a popular game about 1850, was the great summer social game during 1860-70, but was after about 1875 superseded by lawn-tennis, to revive about 1897. A *croquet-ground* should be a well-rolled level grass plat or lawn, not less than 30 yards long by 20 yards wide; a full-sized croquet-ground measures 40 yards by 30 yards.

**Crosier**, or CROZIER, a name strictly belonging to the Pastoral Staff (q.v.) or crook of a bishop or abbot, has often been applied, erroneously, by modern writers to an archbishop's cross. The error seems due to an old confusion between cross, derived, apparently through Irish and Norse, from Latin *cruz*, and the obsolete crose or croce, mediæval Latin *crocia*, a crook. The crosier possibly originated in the *lituus* of the Roman augurs.

**Cross**, an instrument of capital punishment among the ancients. Death by the cross was esteemed so dishonourable that only slaves and

Processional Cross.

malefactors of the lowest class were subjected to it by the Romans. Among the Carthaginians, and probably also among the Phœnicians and allied races, it was employed as an instrument of sacrifice to Baal. Thus the Carthaginian general, Mæcus, invested his son, Cartalo, in royal raiment, with a crown on his head, and crucified him to obtain a special favour from Baal. It has been suggested that there may be some allusion to these crucifixions to the sun in Num. xxv. 4; Josh. viii. 29; x. 26. Among the Gauls, as shall be noted later, a cross of equal arms was a solar symbol. It was customary among the Romans to proclaim the name and offence of the person crucified, or to affix a tablet (*album*) to the cross, on which they were inscribed. Malefactors were sometimes fastened on a simple upright stake, and so left to die, or they were impaled upon it, and to this upright stake the Latin name *crux* was originally and more strictly applicable; but very generally a cross-piece (*patibulum*) was added to the stake, to which the arms of the criminal were tied, or to which his hands were nailed. When the cross-piece was fastened at right angles below the summit of the upright stake, the cross was called *crux immissa*; when the cross-piece was fastened at right angles across the top of the upright stake, the cross was *crux commissa*; and when it was formed of two beams crossing one another obliquely, it was *crux decussata*. There was often a projection, on which the body rested, as on a seat. The cross was erected without the gates of towns, but in places of frequent resort. The person crucified often lived for days upon the cross.

The death of Christ by crucifixion led Christians to regard the cross with peculiar feelings of reverence, and to make use of the sign of the cross as a holy and distinguishing sign. The custom of *crossing* one's self in honour and commemoration of Christ, can be traced back to the 3d century. It was customary, probably from apostolic times, for the Christians to pray with extended arms; and Justin Martyr and Origen explain this attitude as representing that of Christ on the cross. In this manner Christians are represented in the early paintings in the catacombs as praying. The Emperor Constantine, after obtaining the victory over Maxentius, through the influence, as he believed, of the sign of the cross, caused crosses to be set up in public places and upon public buildings; but the so-called cross of Constantine, or Labarum, was not really a cross, but a circle containing the XPI, the first three letters of the name of Christ in Greek, and was merely an adaptation of a symbol of a Gaulish solar deity (see Gaidoz, *Le Dieu Gaulois du Soleil*), which consisted of a wheel of six spokes, or sometimes of four. After the *Invention of the Cross*, or finding of the alleged true cross of Christ in Jerusalem, which was supposed to have taken place in a search made on Calvary by the Empress Helena (q.v.) in 326 A.D., a surprising quantity of the relics of the cross were distributed through all parts of Christendom. When a portion of the cross was given to St Radegund by Justin II, emperor of the East, and she desired to have the relic received with honour into the city of Poitiers, the Bishop Maroveus peremptorily refused to allow it. She was obliged to appeal to King Sigebert, and he ordered the Archbishop of Tours to receive the relic. Maroveus left the town rather than countenance what he regarded as a superstitious act. For this occasion Venantius Fortunatus wrote the famous hymn 'Vexilla regis,' and it was first sung on the introduction of the relic processionally into Poitiers, circa 580. Various other protests were made against the extension of the worship of the relics, but in vain. The sign of the cross is made not only by Roman Catholics, but by the members

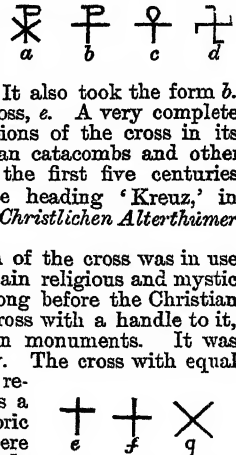

of the Eastern churches also; by the Westerns from left to right, by the Easterns from right to left. It is admitted by the Lutherans as a commemorative sign of the atoning death of Christ, but by many Protestants is rejected as a human invention in worship, and as tending to superstition. It was very generally used during the middle ages, and still is among the less enlightened peasantry in some Roman Catholic countries as a sort of charm, or as affording some security, like an amulet, against all evil, and particularly against evil spirits and witchcraft. The festival of the Invention of the Cross is celebrated on the 3d of May; that of the Elevation of the Cross commemorates the re-erecting of the cross at Jerusalem by the Emperor Heraclius in 628, after it had been carried away by the Persians. See *Legends of the Holy Rood*, edited by Richard Morris for the Early English Text Society (1871); and the *Legendary History of the Cross*, by Ashton and Baring-Gould (1887).

The earliest mention of representations of the crucifixion are by two writers in the 6th century. Gregory of Tours relates that such a picture was in one of the churches of Narbonne, and gave offence because it was nude; and the rhetorician Choricus says that in a church at Gaza was a representation of Christ crucified between two thieves. See CRUCIFIX. As neither of these writers remarks on the novelty of such representations, it may be supposed that they were not infrequent in the 6th century. Early crucifixes were, in contradistinction to that mentioned by Gregory, clothed to the feet. In the treasury of Monza are two such, one given by Gregory the Great in 599 to Adalwald, son of Queen Theodolinda, and another of the 6th century with a Greek inscription. The use of the cross without a figure of Christ is much earlier. As already mentioned, it was employed as a sign made with the hand, or by extension of the arms, at an extremely early Christian epoch; but no crosses are found represented in the catacombs of Rome before the 5th century, excepting the so-called cross of

Constantine, *a*, which is not a cross but a monogram. This symbol is found first in the beginning of the 4th century. It also took the form *b*. Then it became a plain cross, *c*. A very complete list of all the representations of the cross in its various forms in the Roman catacombs and other Christian monuments of the first five centuries will be found under the heading 'Kreuz,' in Kraus, *Realencyclopädie d. Christlichen Alterthümer* (1886).

It appears that the sign of the cross was in use as an emblem, having certain religious and mystic meanings attached to it, long before the Christian era; the *crux ansata*, or cross with a handle to it, *c*, is common on Egyptian monuments. It was the symbol of immortality. The cross with equal arms, and the cross with returned arms or *fylfot*, *d*, is a symbol found on prehistoric relics in Italy and elsewhere (see Mortillet, *Le Signe de la Croix avant le Christianisme*, 1866). The Spanish conquerors were astonished to find it an object of religious veneration among the natives of Central and South America, where it was a symbol of the god of rains. See also PALENQUE and SVASTIKA.

The forms given to crosses in art are endless; but the two leading types are the Latin cross, *e*, or *crux immissa*, supposed to be that on which Christ suffered, and the Greek cross, *f*, both of which are subject to many fantastic variations. The Greek cross forms the well-known cross of St George, which was the national ensign of the English

previous to the union with Scotland. The cross of St Andrew, *g*, differed entirely in form from the Latin or Greek cross. This cross, or *crux decussata*, consisted of two shafts of equal length crossed diagonally at the middle, as in the annexed cut. According to the legend, this was the form of cross on which St Andrew, the national saint of Scotland, suffered martyrdom (see ANDREW). As the Scottish ensign, it is now blended with the cross of St George in the Union Jack. See FLAG.

The Cross of the Resurrection is a floriated cross; and is usually represented as heading a lance, to which is fastened a banner upon which a cross is depicted. The earliest and finest floriated cross is that in the mosaic of San Ponziano, where, however, the flowers spring from the shaft, and on the arms stand two lighted candles. The idea of the floriated cross seems to have been to connect it with Aaron's rod that budded, and so to signify the eternal priesthood of Christ.

In mediæval times a cross, the Rood, stood over the screen between the nave of a church and the chancel. This was always veiled in Lent. The crutched cross, like the letter T, was the symbol of St Anthony the Hermit. *Processional* crosses—double for archbishops—are those carried in processions; *pectoral* crosses, those worn on the breast by ecclesiastics of rank. Many orders have distinctive crosses. See LEGION OF HONOUR.

The *Order of the Cross*, originally a spiritual order of knighthood, sprang up in Palestine in the time of the Crusades, and was then called the *Bethlehemite Order*. Pope Gregory IX. confirmed the order in 1238. Its principal seat was in Bohemia.

*Sanctuary, Boundary, or Monumental Crosses*, as they are called, consist of an upright flat pillar or obelisk, covered with sculptural devices, and set

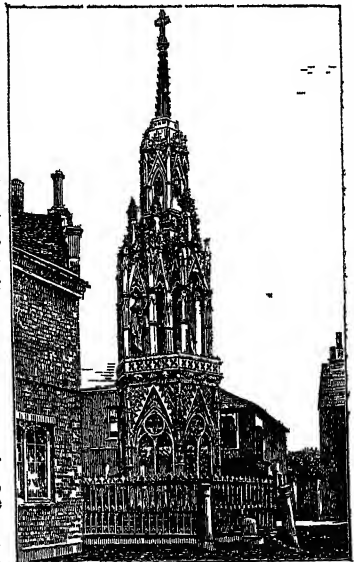

*Celtic Cross*, most frequently found in Ireland and in the north and west of Scotland. Such crosses vary much, from a cross incised on a flat slab to an elaborate cruciform monument. The majority of the latter seem to belong to the period between the 12th and 15th centuries. One of the best known is that at Iona called St Martin's Cross, standing in the grounds of the cathedral. It is a column of compact mica schist, 14 feet high, 18 inches broad, and 6 inches thick, and is fixed in a pedestal formed out of a massive block of red granite, about 3 feet high. In connection with certain ancient religious houses in Ireland, there were very fine Celtic crosses. For Celtic crosses, and for the *Runic* crosses of Anglo-Saxon Britain (as at Ruthwell and Bewcastle), Man, and the Western Isles of Scotland, see the articles SCULPTURED STONES and RUNES.

*Churchyard Crosses* seem to have existed in all churchyards before the Reformation: some still exist, and the remains of others are numerous. In France, in connection with the cemetery cross, in some parts, a perpetual lamp was kept burning, and the contrivance for the lamp remains in some of them.

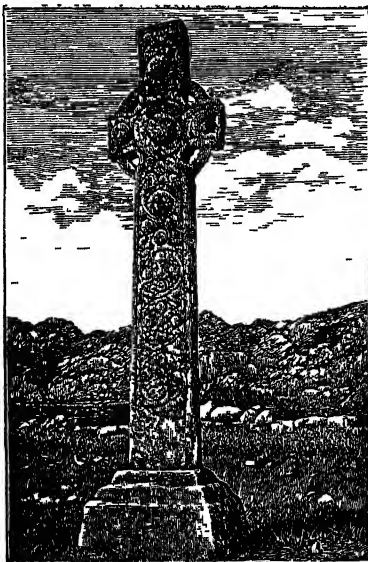

Many very beautiful crosses exist in England, upon the points of gables of churches, or grave-stones, and in other situations, as also in heraldry. Among these, the cross most commonly seen is called the *cross crosslet* (see below).

*Memorial Crosses* are such as are erected in memory of a beloved object, or in commemoration of some event of local importance. In England there are some superb crosses of this kind; they are popularly called *Norman Crosses*. This species of cross resembled a Gothic turret set on the ground, or on a base of a few steps, and was decorated with niches for figures and pinnacles.

The best-known examples are those erected by Edward I. (1290) in memory of his queen, Eleanor; being placed on the spots where the body rested in its funeral progress to Westminster. Of these the original cross at Geddington, near Kettering, still stands, and that at Hardingstone, near Northampton, is one of the finest monuments of mediæval art in Britain; the cross at Wal-

Waltham Cross, restored.

St Martin's Cross, Iona.

in a socket level with the ground. Occasionally, they appear to have marked boundaries, but more frequently were monuments over the graves of heroes, kings, bishops, &c. A vast number of extremely rude and early crosses of granite occur in Cornwall and Devon: some of these have apparently been fashioned out of prehistoric monoliths. In some instances, they probably marked the verge of a sanctuary. A characteristic type of cross is the

tham was repaired in 1890; that at Cheapside no longer stands; that at Charing was removed by parliament in 1647: a reproduction occupies its site.

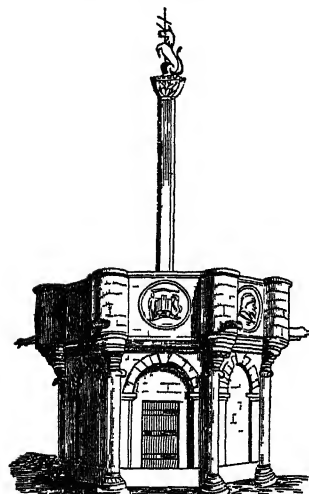

*Village Crosses* stood in the centre of most villages in ancient times. In the west of England a good many remain.

*Town or Market Crosses* were erected as stands to preach from, or in commemoration of events regarding which it was deemed proper to evoke pious

feelings. As these structures were incorporated with or surmounted by a crucifix, the term *cross* was so indelibly associated with them that it survived the religious character of the fabrics. The earliest examples of this kind consisted, probably, of tall crucifixes of wood, such as are still seen by the waysides in some continental countries. Afterwards, stone shafts would be substituted; and according to the increase of market revenues, or progress of taste, these town-crosses assumed that imposing character which they latterly possessed. The crosses at Cheddar in Somersetshire and at Malmesbury in Wiltshire, are open vaulted structures, with a commodious space beneath as a refuge for market-folks during rain, and surmounted with a kind of Gothic turret. At Chichester, Bristol, and Winchester, the market-crosses, while similar in form, are of a higher architectural quality. Adjoining St Paul's in London stood Paul's Cross, a structure which we read of as early as 1259, in the reign of Henry III. At this *preaching cross*, by order of Henry VIII., preachers delivered sermons in favour of the Reformation, and here Queen Elizabeth attended to hear a thanksgiving sermon for the defeat of the Spanish Armada; but in 1643 the cross incurred the displeasure of the Puritans, and was demolished by order of parliament. See books by Alfred Rimmer (1875) and Aymar Vallance (1920).

Scotland offers no specimens of memorial or Norman crosses, unless it be the modern Scott Monument, at Edinburgh, which is essentially a Norman cross of a gigantic order. The simpler kind of Scottish market-cross consisted of a shaft of stone, standing on a flight of circular or octangular steps—the grander market-cross consisted of a tall stone shaft, on an imposing circular, hexagonal, or octagonal substructure, 10 to 16 feet high. The top formed a platform, which was surrounded with an ornamented stone parapet, and was reached by a stair inside. Losing their religious character, the

Scottish market-crosses were employed for royal and civic proclamations, and as places where certain judicial writs were executed. The oldest cross of Edinburgh stood in the centre of the High Street, but was removed in 1617. A new market-cross was then erected farther down the street, on the south side, which consisted of an octangular base, with a stone shaft of about 20 feet in height; its removal in 1756, by the civic authorities, is in-

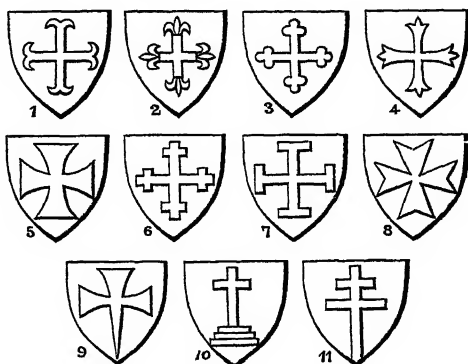

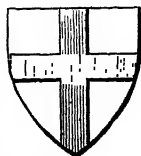

Edinburgh Old Market-cross.

dignantly referred to by Scott in *Marmion*. The shaft, which had been preserved, was re-erected on a similar substructure near the same site in 1885, at the expense of Mr Gladstone. See Small, *Scottish Market Crosses* (1900).

CROSS, in Heraldry, is one of the ordinaries, and is considered to occupy one-fifth of the field if not charged, and one-third if charged. Argent, a cross gules, is the cross of St George. Like

other ordinaries, the cross may be *engrailed*, *invected*, &c. When its central square is removed, it is said to be *quarter-perced*; and when it does not extend to the margin of the shield, it is called *huettee*. But the cross of heraldry is often found varied in other ways, the varieties having each separate names. Thirty-nine varieties are enumerated by Guillim, and 109 by Edmonson. Those most frequently occurring are here mentioned; and it may be remarked that they St George's Cross, have rather the character of common charges than ordinaries not extending to the margin of the shield, and being often borne in numbers as well as singly. The *cross moline* (fig. 1) has the ends turned round both ways; the *cross fleury* (fig. 2) has each end terminating in a

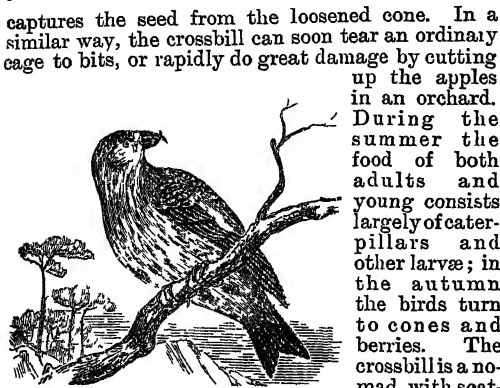

fleur-de-lis; the *cross bottonnée* (fig. 3) has each end terminating in a trefoil; the *cross patee* (fig. 4) has three points to each limb; the *cross pattee* (fig. 5) is small in the centre, but widens towards the ends; the *cross crosslet* (fig. 6) is crossed at each end; and the *cross potent* (fig. 7) is crutch-shaped at each end. The *Maltese cross* (fig. 8), which converges to a point in the centre, and has two points to each limb, though not frequent as a heraldic charge, derives importance from being the badge of the Knights of Malta and other orders. Any of these crosses is said to be *fitchée* when the lower limb terminates in a point, as in fig. 9, representing a *cross pattee fitchée*. Besides these and other crosses with equal limbs, there is the *cross Calvary* (fig. 10), being the cross of crucifixion elevated on three steps, and the patriarchal cross (fig. 11) with two horizontal bars.

**Cross, MARIAN.** See ELIOT, GEORGE.

**Cross, SOUTHERN.** See SOUTHERN CROSS.

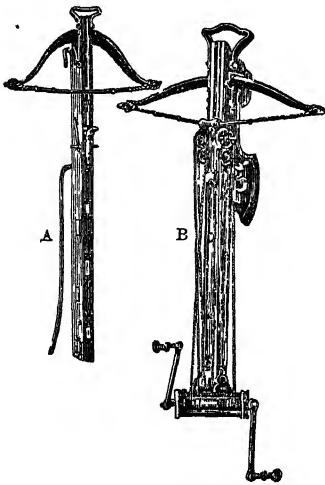

**Cross Bill,** a bill of exchange or promissory note given in consideration of another bill or note.

**Crossbill** (*Loxia*), a Passerine bird in the finch family (Fringillidae), well known for the curious way in which the points of the upper and lower bill-halves cross one another. There seems to be no constancy in the direction of crossing, for in different individuals, even of the same species, the upper and lower portions are found variously directed to right or left. This peculiarity is probably for the most part a directly mechanical adaptation to the food-habit of the bird, which consists in tearing up the cones of firs and pines for the sake of the seeds. Bringing the two points together, the crossbill inserts its beak into the cone, then opens it with a strong lateral movement, and with its scoop-like tongue detaches and

Crossbill (*Loxia curvirostra*).

captures the seed from the loosened cone. In a similar way, the crossbill can soon tear an ordinary cage to bits, or rapidly do great damage by cutting up the apples in an orchard. During the summer the food of both adults and young consists largely of caterpillars and other larvae; in the autumn the birds turn to cones and berries. The crossbill is a nomad, with scattered breeding-places in Britain and throughout Europe. The so-called parrot crossbill (*L. pityopsittacus*) is merely a large-billed variety. The two-banded crossbill (*L. bifasciata*) is a very rare visitor to Britain. Altogether seven species are known, from the northern regions of both hemispheres, and always found gregariously in conifer forests. The crossbill has become associated with a sacred legend, familiar in Longfellow's poem; the bird was fabled to have sought, by pecking at the nails, to free Christ from the cross.

**Crossbow**, or **ARBALEST**, a weapon used in war and sport in medieval times. It consisted of a wooden stock, with a bow made of wood, iron, or steel, crossing it at right angles to the end; the bowstring was pulled down towards the other end of the stock by a lever (which in the simpler kinds was worked by hand or foot), and retained in position sometimes in a notch by a catch or trigger. The bolt or 'quarrel' was then laid in a groove on the top of the stock, and the trigger being pulled, it was shot with a considerable amount of power. The latter, of course, depended on the size of the bow, some of the weapons being comparatively small and easily handled, while others were of large dimensions, and required a machine of the nature of a windlass, called a 'moulinet' or 'gaffie,' to enable the bow to be properly bent. The crossbows of the 14th century were almost all thus equipped. The 'quarrels' employed varied with the size of the bow, but generally they were short stout shafts about 18 inches long, winged with horn or leather, and having a metal point, which was sometimes sharp, but often lozenge-shaped, obtuse, and indented at the sides. Some crossbows had a tube or barrel, with a slit for the bowstring, and dis-

A, Hand Crossbow; B, Rolling-purchase Crossbow.

charged balls of clay, marble, or lead with such force that they were more formidable weapons than the earliest firearms. The larger crossbows were really military engines, which required several men to work them, and threw proportionally heavy missiles (see **BALLISTA**). The crossbow was used in England chiefly during the 13th century; after that it gave place to the longbow, which was found to be the more convenient and easily handled weapon of the two. Its use, however, was general among the continental nations of Europe after the 12th century; though the Lateran Council of 1139 forbade its use as being too murderous a weapon for Christians to employ. See Sir R. Payne-Gallwey, *The Crossbow* (1903).

**Cross-breeding.** See **BREED**.

**Cross-buns**, a small cake specially prepared for Good-Friday, and in many towns of England cried about the streets on the morning of that day as 'hot cross-buns.' *Bun* is, according to Skeat, ultimately of Scandinavian origin. There is an Old Fr. word *bugne*, 'a swelling,' which may be the immediate source of the English word. Good-Friday buns were appropriately marked with the cross, and hence the name. The origin of the practice is obscure. Most probably it is a relic of some heathen observance, to which the early church gave a Christian significance. At Chelsea, there were formerly two celebrated bun-houses, besieged on Good-Friday from morning until night by hundreds of eager purchasers, but they have long since disappeared.

**Crosse**, **ANDREW**, electrician, born at Fyne Court, Somersetshire, 17th June 1784, was educated at Bristol and at Brasenose College, Oxford. His principal researches in science were as to the artificial formation of minerals by processes of electrical deposition and the application of electricity as a means of improving wines, cider, &c. In 1837 he announced that under certain circumstances, organisms (of the genus *Acarus*) appeared in solutions of inorganic substances; a discovery which attracted much attention, but which exposed him to the ridicule of opponents. He died 6th July 1855. See *Memoir* (1857) by his second wife; and her *Red Letter Days of my Life* (1893).

**Cross-examination.** See **EVIDENCE**.

**Crossley**, **SIR FRANCIS**, manufacturer and philanthropist, was born at Halifax, October 26, 1817. His father was the founder of the Dean Clough Carpet Mills. Sir Francis encouraged the inventor George Collier to produce a greatly improved carpet-loom; the mills increased till 6000 hands were employed; while carpets were much cheapened in price, and their use greatly extended at home and abroad. Amongst Sir Francis's benefactions to Halifax were a public park (1857) at a cost of £40,000, almshouses, and orphan homes, besides large donations to the London Missionary Society and to the Congregationalists. A baronetcy was conferred on him in 1863, and from 1852 till his death on 5th Jan. 1872 he represented Halifax and the West Riding as a Liberal.

**Crossopterygii.** See **FISHES**, **POLYPTERUS**.

**Crossraguel** ('*Crux Regalis*'), a ruined abbey in Ayrshire, 2 miles SW. of Maybole. It was a Clugniac foundation, a daughter of the Paisley abbey, and dates from 1244. A notable 'disputation' took place in 1562 between John Knox and the abbot, Quentin Kennedy; and in 1570 the commendator was 'roasted' or severely tortured by fire by the Earl of Cassilis, to force him to resign certain lands.

**Crosswort** (*Galium Cruciata*), a British species of Bedstraw (q.v.), with leaves in whorls of four, and yellow flowers in small axillary cymes.

**Crotal.** See BELL, CASTANETS.

**Crotalaria** (Gr. *krotalon*, 'a rattle'), a tropical genus of papilionaceous Leguminosæ, deriving its name from the inflated pods in which the seeds rattle when ripe. The species are annual, perennial, and shrubby plants, some of which yield valuable fibre, particularly *C. juncea*, the Sunn, or Hemp Sana, or Janupa Hemp of India, an annual species. The perennial *C. peduncularis* (Jubbulpore Hemp) is grown in Southern India, and other species or varieties are in cultivation. Several species are North American.

**Crotalidæ.** See RATTLESNAKE.

**Crotch.** WILLIAM, composer, was born at Norwich in 1775. His musical genius was quite as precocious as that of the great Mozart. When little more than two years old he could play *God save the King* with chords, and in 1779 he was performing in London as a musical prodigy. When only twenty-two he was appointed professor of Music in Oxford University, and in 1822 he obtained the principalship of the Royal Academy of Music. Crotch composed a large number of pieces for the organ and piano, two oratorios, ten anthems, &c.; and he was author of *Elements of Musical Composition* (1812) and *Styles of Music of all Ages* (1807-18). He died at Taunton, December 29, 1847.

**Crotchet.** See MUSIC.

**Croton**, a genus of plants of the natural order Euphorbiaceæ, with numerous species, which are mostly tropical or subtropical trees or shrubs, a few herbaceous. The most important is the Purging Croton (*C. Tiglium*), a small tree, a native

Croton.

of India and the more easterly tropical parts of Asia. The leaves are extremely acid; the wood in a fresh state is a drastic, and in a dried state, a more mild purgative; and the seeds (*Croton Seeds*, or *Tilly Seeds*) are a very powerful drastic purgative, formerly much employed in Europe, but latterly disused on account of violence and uncertainty of action, although still valuable as yielding croton-oil. They are oval or oval-oblong, about the size of field-beans. So great is their acidity, that dangerous effects have ensued from working for some hours with packages of them. The oil is obtained mostly by expression, and partly by treating the cake with alcohol. Other species possess similar properties. Very different are the properties of the species which yield Cascarella (q.v.) and Copalchi (q.v.) barks. Other species are still

more aromatic, and some delightfully fragrant, containing in great abundance a thickish balsamic sap. The sap of *C. gratissimus* is employed as a perfume and cosmetic at the Cape of Good Hope; that of *C. origanifolius* is used in the West Indies as a substitute for Balsam of Copaiva; that of *C. javensis* (or *balsamifer*), also West Indian, furnishes *Eau de Mantes* by distillation; and the balsamic sap of some South American species is dried and used as incense. *C. Draco* and other species yield a blood-red juice, which, when dried, forms the finest kind of dragon's-blood, and has astringent properties.

**CROTON-OIL** is the oil expressed from the seeds of the *C. Tiglium*, and is a sherry-coloured, viscid liquid, with an acrid taste, a somewhat rancid smell, and a fluorescent appearance. It contains a number of oily bodies, none of which have as yet been definitely shown to be the cause of its purgative and vesicating properties. Croton-oil is a violent purgative, in most cases a single drop being sufficient to remove constipation. When rubbed upon the skin it produces rubefaction and pustular eruption, and thereby tends to relieve some affections of the internal organs. It is used either by itself in the unmixed state, or diluted with olive-oil, soap liniment, alcohol, &c. It is not to be employed except under the advice of a doctor.

The name Croton is commonly given by gardeners and others to a plant of another euphorbiaceous genus, *Codiaeum variegatum*, much grown in greenhouses and in the tropics, where it forms hedges. It is a native of the Pacific and Sunda Islands. It is grown for the sake of its variegated leaves, which take many bizarre shapes, being often so narrowed in the middle that one leaf looks like two placed end to end, each with blade and stalk. The blade is often twisted like a propeller.

**Croton.** See CROTONA; and for another often confused with it, CORTONA.

**Crotona**, or CROTON, a city on the east coast of Bruttium in ancient Italy, owed its origin to a colony of Achæans, as far back as 710 B.C. It soon became one of the most prosperous, wealthy, and powerful cities of Magna Græcia. Its walls measured 12 miles in circumference, and the territory over which it extended its sway was considerable. Its inhabitants were celebrated for athletic exercises, and they carried off most of the prizes at the Olympic games. Pythagoras settled here about the middle of the 6th century B.C., and became a very important member of the body politic (see PYTHAGORAS). About 510 B.C. Crotona sent forth an army of above 100,000 men, under Milo, its most renowned athlete, to fight the Sybarites; the latter, though three times as numerous, were utterly defeated, and their city destroyed. The war with Pyrrhus completely ruined the importance of Crotona, and in the 2d century B.C. it had sunk so low that a colony of Romans had to be sent to recruit its well-nigh exhausted population. It never afterwards recovered its prosperity. Some ruins belonging to the old exist in the vicinity of the modern city (called Cotrone, q.v.); and very fine Greek coins have been found. Cortona (q.v.) was also anciently called Crotona.

**Croton Bug.** See BOOKWORM.

**Croton River**, a river of New York State flowing to the Hudson, 30 miles above New York City, has in its basin the lakes and ponds which form the chief water-supply of the city, conveyed through famous aqueducts. See AQUEDUCT.

**Crotophaga** (Gr. 'tick-eater'), a genus of birds in the cuckoo family and order Coccothymophæ. They are also known by the names Ani and Keel-bird, the former referring to the cry, the latter to the blade-like ridge on the compressed arched beak. The best known of the three species (*C. ani*) fre-

quents South America to the east of the Andes, and is often called the Savanna Blackbird. They are distinguished from other cuckoo-like birds by the tail, which has only eight steering feathers. The beak is as long as the head, and the keel is said to be used in unearthing their insect prey; the wings are long and pointed; the tail is long, broad, and rounded. They are social birds, and several females lay their eggs in a common nest. They are fond of keeping about herds of horses and cattle, and destroy insect larvæ on their skin.

**Crotus Rubianus**, otherwise JOHANNES JAGER, German humorist and satirist, is now universally recognised as author, with Ulrich von Hutten, of the *Epistolæ Obscurorum Virorum* (q.v.). His was probably the first conception; and he wrote the forty-one letters of the first series, though probably not without collaboration. He was born about 1480 at Dornheim in Thuringia, whence Rubianus (from *rubus*, a translation of *Dorn*). *Crotus*, a synonym of *Sagittarius*, represents Jager. From goat-herding he passed to Erfurt University in 1498. There he was of the humanist coterie of Mutianus Rufus, and was a friend of Ulrich von Hutten and of Martin Luther. In 1510-15 he was master of the monastic school of Fulda, and from 1517-20 a tutor at Bologna. Later he returned to the Roman Catholic Church; but never quite at home again in it, he suffered the attacks of Lutheran controversialists in silence, and died forgotten about 1540, probably at Halle, where he had received a canonry in 1531. See Walther Brecht, *Die Verfasser der Epist. Obscur. Vir.* (Strassburg, 1904), and F. G. Stokes's edition with English translation (1909).

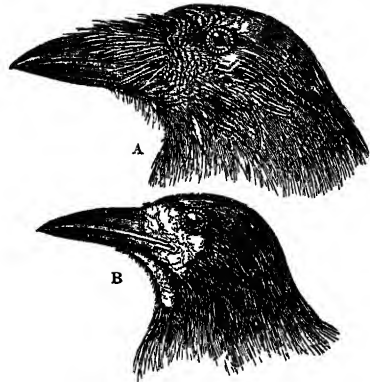

**Croup**, a term used in Scotland from an early period to describe a certain train of laryngeal symptoms, was adopted by Dr Francis Home, in 1765, for an acute inflammatory affection of the Larynx (q.v.), in which there is the formation of a false membrane or fibrinous deposit on the mucous surface of the throat or windpipe. The word has only an historical interest, and its use is not now justified. The investigation by bacteriological methods of the causes of the various types of sore throat has shown that most of the conditions going under the name of croup are in reality cases of Diphtheria (q.v.), though some of the more severe manifestations of simple tonsillitis also fall to be included.

**Crow** (*Corvus*), a genus of Passerine birds, and type of a family Corvidæ, which also includes Magpies (*Pica*), Nutcrackers (*Nucifraga*), Jays (*Garrulus*), Choughs (*Fregilus*), and other genera. The crow family is included in that division of Passeres known as Acromyodi, from peculiarities in the vocal organs, and its members share the following characters: the bill is moderately long, strong and thick; bristles at the base cover the nostrils; the wings are of medium size and rounded; the tail is not prominent; the feet are strong. On the whole they outdo the other Passeres in size and strength, and are represented by towards two hundred species.

Keeping first to the crow genus proper (*Corvus*), we need give little description of the general characters of these familiar birds. The long black bill, the large gape, the tail all but covered by the wings, the black feet, &c. are well-known characteristics. The genus is distributed in most parts of the world except South America and New Zealand. They are essentially tree birds, and almost always build their nests there. In diet they are predominantly vegetarian. It is important to distinguish the four British species of crow. (1) The Raven (*Corvus corax*) is a well-known species in Europe and North Asia. Its black plumage has a

bluish sheen; the upper portion of the bill is bent over the lower; the wings reach the point of the tail. It is a hungry bird, devouring *inter alia* field-mice and small birds; it is not unfrequently tamed, and can be readily taught to ejaculate and play tricks. See RAVEN.

(2) The Rook (*C. frugilegus*) is a commoner smaller species of gregarious habit. There is the same metallic shimmer, the wings again reach the tail, but the upper bill is not elongated over the lower. The face becomes curiously bare during the first winter, and so remains. It is of use in destroying injurious insects, but its omnivorous appetite includes eggs, young birds, fish, walnuts, corn, &c. See ROOK. The accompanying figure

shows the heads of the raven, A, and the rook, B, and illustrates well the prevalent characters of the bill in this genus. It shows also in the raven the bristles which, as in most of the species, surround its base, but which are wanting in the rook. Noteworthy, too, is the greater strength of neck, head, and bill of the more carnivorous as compared with the more frugivorous species.

(3) The Hooded Crow (*C. cornix*) derives its name from the fact that while the general colour is ashen gray, the head is black. The under throat, the wings, and the tail are also, however, black. Like the next species, the hooded crow is fond of carrion, and both are often shot by gamekeepers on account of the damage they do to young game-birds, &c.

(4) The Carrion Crow (*C. corone*, or *Corone hiemalis*), which is of the same size as the rook, has black plumage, with a steel-blue shimmer on back and head, and wings which do not reach the tip of the tail. The bases of the feathers are gray in the rook, white in the carrion crow. It is useful in destroying mice and insects. It is said to interbreed with the preceding species. The name is given in America to a Vulture (q.v.). In some parts of Scotland the carrion crow is called the *Hoody*. There is considerable dispute as to the specific dignity of some of the crows. A few other forms in addition to the above four may be noticed. The crow of North America (*C. americanus*) is very similar to the carrion crow, but rather smaller, and, after the breeding season is over, congregates into great flocks; it is also partially migratory, great numbers from the more northerly parts moving to the south on the approach of winter. Its habits are otherwise intermediate between those of the carrion crow and the rook.—The Fish Crow (*C. ossifragus*) frequents the coasts and southern rivers of the United States, feeding chiefly on fish, which it catches with great dexterity. It also sometimes assails gulls, and compels them to disgorge their prey.—The Jabbering Crow (*C. jamaicensis*) of the Blue Mountains of Jamaica

is remarkable for the resemblance of its voice to human speech. Sir J. E. Tennent gives an interesting account of the small glossy gray-necked crow of Ceylon (*C. splendens*), which frequents the towns, feeding on offal, and boldly enters rooms through open windows, to snatch some morsel from the dinner-table. See also CHOUGH, JACKDAW, LAY, MAGPIE.

**Crowberry**, or **CRAKEBERRY** (*Empetrum nigrum*), a small procumbent shrub, with characteristically inrolled leaf-margins, of the order Empetraceæ, a native of the colder northern parts of the world, and the Andes, abundant in the moors of Scotland and the north of England, and common throughout Canada, Alaska, and Siberia. The order consists of a few heath-like shrubs, which, however, are usually associated with Euphorbiaceæ, with small trimerous, usually unisexual flowers, the

Crowberry (*Empetrum nigrum*):  
a, flowering branch; b, flowers enlarged; c, fruit.

fruit a small berry seated in the persistent calyx. The berries of the crowberry are nearly black, surround the branches in crowded clusters, and contain six to nine bony seeds and a watery acidulous juice. A fermented liquor is prepared from them in some northern countries. They are a favourite food of game. The variety *E. rubrum*, of Cape Horn, differs little, except in having red berries. The berries of the Camarinheira (*Corema alba*) are employed in Portugal for the preparation of an acidulous drink in fevers. The plants of this order, especially *E. nigrum*, have taken considerable part in the formation of peat.

**Crowe**, MRS CATHERINE (née Stevens), authoress, was born at Borough Green, in Kent, in 1800. In 1822 she married Lieutenant-colonel Crowe, and spent great part of her after-life in Edinburgh. She died in 1876. Her mind was morbid and despondent, ever hovering on the border-line of insanity, which it crossed once in one violent but brief attack. Her translation of Kerner's *Seeress of Prevorst* (1845) prepared the way for her well-known *Night Side of Nature* (1848), a great collection of supernatural stories, told, indeed, with vigour and verisimilitude, but hopelessly credulous and uncritical. She wrote also tragedies, juvenile books, and novels; of the last, the best, *Susan Hopley* (1841) and *Lilly Dawson* (1847). Her *Spiritualism and the Age we live in* (1859) has no value, save as autobiography.

**Crowe**, SIR JOSEPH ARCHER, art-writer, born in London in 1825, studied and travelled widely on the Continent, where in 1847 he met Cavalcaselle; their joint works will be found in the article CAVALCASELLE. Crowe was a special correspondent in the Crimean war, the Indian mutiny, and the Franco-Austrian war; and in 1857-59 was director of the School of Art at Bombay. In 1860 he was appointed British consul-general at Leipzig, and afterwards at Dusseldorf; in 1882 he was named commercial attaché at Paris. Made a C.B. in 1885, he was raised to the dignity of K.C.M.G. in 1890. He contributed the article RAPHAEL to this work. He died 6th September 1896. See his *Reminiscences* (1895), mainly of his career as journalist.

**Crowfoot**. See RANUNCULUS.

**Crow Indians**, some 4000 in number, of the Dakota stock, live on reservations in Montana.

**Crowland**, or **CROYLAND**, an ancient market-town in the south of Lincolnshire, on the Welland, in the Fens, 10 miles NNE. of Peterborough. Here in 716 King Ethelwald founded a monastery in honour of the hermit St Guthlac, which, burned by the Danes in 870, and again destroyed by fire in 1091, was restored in 1113, and thereafter became a mitred Benedictine abbey of singular magnificence. The north aisle of its church now serves as the parish church, and part of the west front and the famous bell-tower (1427) still remain. Ingulph (q.v.) was abbot of Croyland. See G. Perry's *Croyland Abbey* (1867). The 'Triangular' or 'Three-way Bridge' is described at BRIDGE.

**Crown** (Lat. *corona*). The crown of classical times was a circular ornament of metal, leaves, or flowers, worn on festive and solemn occasions, and as a reward of worth, talent, or military or naval prowess. Among the Greeks the crown (*stephanos*) was sometimes used as an emblem of office, as in the case of the archons; sometimes as an ornament for the heads of the victors in the public games; and sometimes as a mark of distinction for citizens who had merited well of their country. The Romans made great use of crowns as rewards for valour. The most highly prized was the *corona obsidionalis*, which was bestowed by a beleaguered garrison or army on the general who rescued them. It was made of grass or wild-flowers, gathered from the place which had been beset by the enemy. Next in order was the *corona civica*, a garland of oak leaves and acorns, which was given as a reward to any soldier who had saved the life of a Roman citizen in battle; the *corona navalis*, a gold circle decorated with beaks of ships, was the reward for naval services; the *corona muralis*, a similar circle surrounded with battlements, was bestowed on him who first scaled the walls of a besieged city; and the *corona vallaris*, a circle ornamented with palisades, on the first soldier who forced his way into the enemy's camp. There was also the *corona triumphalis*, bestowed upon a general when he obtained a triumph.

Other crowns were emblematic, such as the sacerdotal, funeral, convivial (of roses, violets, myrtle, ivy, and even parsley), and nuptial crowns. The custom of wearing bridal wreaths or even bridal crowns of metal is not unknown in modern Europe as in Germany and Norway and medieval England; and the bridal wreaths of young brides are still suspended in some Derbyshire churches. (1) *Corona sacerdotalis*, worn by the priests and bystanders when engaged in sacrifice. (2) *Corona funebris* or *sepulchralis*, with which the dead was crowned, a custom which prevailed both among the Greeks and Romans. In Greece, these crowns were commonly of parsley. (3) *Corona convivialis*, worn by guests on festive occasions.

As the emblem of sovereignty in modern Europe, the crown was borrowed less from the crowns of antiquity than from the diadem, a fillet of silk, linen, or woollen. This decoration was originally oriental. Alexander the Great adopted it from the kings of Persia; and Antony assumed it during his luxurious intercourse with Cleopatra. In modern states, crowns have been of various forms, and undergone various changes. The royal crown of England in the 12th and 13th centuries was a jewelled circlet of gold, heightened with strawberry-leaves or trefoils, sometimes alternately large and small. In the very costly and magnificent crown of Henry IV., the strawberry-leaves, eight in number, alternated with as many fleurs-de-lis, the whole alternating with sixteen small groups of pearls. The same crown was worn by Henry V. in the beginning of his reign, but on undertaking his French campaign he ordered it to be broken up, and the fragments distributed as security for the loan required by him to carry on the war. The crown that succeeded it was probably an arched one; for although no arched crown appears on the Great Seal of any monarch before Edward IV., the arched as well as the unarched form of crown is found occasionally in sculptures and illuminations of the reigns of Henry V. and Henry VI. The crown of Edward IV. (which was probably also worn by Henry V. and Henry VI.) differs from previous crowns in being arched over with jewelled bands of gold, closing under a mound ensigned by a cross patée, while crosses patée are substituted for the strawberry-leaves, and roses or fleurs-de-lis for the clusters of pearls. During succeeding reigns down to that of Charles II., the crown underwent various minor changes of form.

Fig. 1.

usually known in this country as the imperial crown, and represented in fig. 1. It has four crosses patée and four fleurs-de-lis set alternately

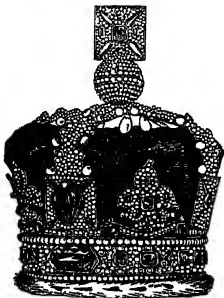

Fig. 2.

on the circlet, while two complete pearl-studded arches rising from within the crosses patée carry at their intersection the mound and cross. A new state crown was made for the coronation of Queen Victoria, differing somewhat from the imperial crown. Its arches rise almost perpendicularly, are elevated rather than depressed at their intersection, and assume the form of wreaths of rose, thistle, and shamrock, formed of brilliants; and the crown itself is covered with diamonds and studded with costly gems (fig. 2). In official representations of the royal arms, they are ensigned by the imperial crown, but a graceful modification of that crown is sometimes made use of instead of it with His Majesty's sanction (fig. 3). For the coronets of the members of the royal family and of the nobility generally, see CORONET.

The crown of Scotland, long lost sight of, was in 1818 discovered, along with the other Regalia (q.v.), in a chest in Edinburgh Castle. Its gold circle, richly jewelled and enamelled, is heightened with ten fleurs-de-lis, alternating with as many crosses fleury, each adorned in the centre with a great diamond between four large pearls put crossways. Four gold arches, added in the reign of James IV., close under a mound, on which rests a large cross patée, with four pearls at the extremities, and as many in the angles. Excepting the arches, the crown is probably of the date of Robert Bruce.

In the crown of the kings of France the circle was heightened with fleurs-de-lis; and from the time of Francis I. it was closed with eight arches,

Fig. 3.

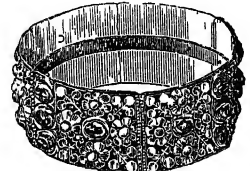

Fig. 4.

from whose intersection rose a fleur-de-lis. The crown of the old German emperors, later the Austrian emperors, is cleft in the centre, so as to present an appearance suggestive of a mitre. The adoption of this crown by Charles V. seems to have resulted from the kings of France having, in emulation of the emperors, assumed a close crown. The iron crown of the ancient Lombardic kings (fig. 4)—restored to the king of Italy by the emperor

of Austria in 1866—is alleged to have been bestowed by Pope Gregory the Great on Queen Theodolinda, and with it Henry of Luxemburg and succeeding emperors were crowned. It is a gold circle with enamelled flowers and jewels, within which is a thin fillet of iron, which has been asserted to have been hammered from a nail of the true cross. The crown (afterwards altered) of the Hohenzollern German empire is shown in fig. 5. The crown of Rumania is of bronze from cannon captured at Plevna.

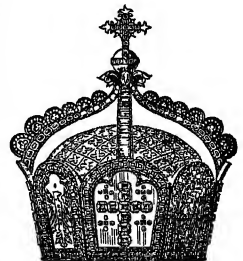

Fig. 5.

The crowns of British kings-of-arms are of silver gilt, with sixteen oak-leaves, each alternate leaf higher than the others, with the motto MISERERE MEI DEUS SECUNDUM TUAM MISERICORDIAM in Roman letters on the circlet.

Crowns occasionally occur as heraldic bearings; among these may be mentioned three of the classical crowns (see above)—viz the crowns mural, a (fig. 6), naval, b,

also the eastern or antique crown, d, a circle with high points rising from it, and the celestial crown, differing from the last in having a star on each point. The imperial crown is chiefly used.

**THE CROWN** is a term employed in England to signify the sovereign authority in the state. In English law the supreme executive power is vested in the crown, and all officers of the state, administrative, military, and naval, from the highest ministers of state downwards, are servants of the crown. The law-making power lies with the crown in parliament. The crown is the fountain of justice. All jurisdiction exercised within the British dominions is derived from the crown, and the judges, who interpret and apply the law, represent the crown. The crown, too, is the fountain of honour, and enjoys the exclusive right of granting pardons. The crown also represents the state in its relations with foreign states. The maxim of law is that 'the King never dies.' The decease of the reigning monarch involves what is termed 'the demise of the crown.' Formerly such demise had the effect of dissolving parliament and vacating offices held under the crown. The crown is immune from civil or criminal liability. Nevertheless, when it is alleged that the crown or any officer of the crown is in breach of contract or is wrongfully detaining property belonging to a subject, a proceeding known as a 'petition of right' is allowed in practice, the effect being that the question at issue is tried by the courts and the property or compensation for the breach of contract may be recovered from the crown. Again, although an action of damages does not lie against the crown in respect of a wrongful act committed by one of its servants, servants of the crown must answer for any wrongful act committed by them; nor can they plead that they acted in obedience to the command of a superior.

**CROWN COLONIES.** See COLONY.

The **CROWN OFFICE**, in England, is the office of the clerk of the crown in Chancery. It is in this office that the Great Seal is, for most purposes, affixed, and the name of the clerk of the crown, appended to a sealed document, is proof that the sealing has taken place on due warrant. From this office are issued the writs for election of members of the House of Commons, and, under the Crown Office Act, 1877, provision is made for the keeping of a record of justices of the peace appointed by royal commission. The **LAW OFFICERS** of the crown are the Attorney-general (q.v.) and the Solicitor-general (q.v.). Criminal informations—i.e. written complaints made on behalf of the crown—may be filed by the Attorney-general, and also by the Master of the Crown Office, provided, in the latter case, permission has been obtained from the King's Bench Division. In legal proceedings, the term crown is used generally as meaning the government department concerned. The **CROWN-SOLICITOR** is the solicitor to the Treasury. Prior to 1908 the solicitor to the Treasury for the time being also held the office of Director of Public Prosecutions, but, by a statute of that year, this office has been separated from that of the Treasury-solicitor and made an independent appointment. The **CROWN OFFICE RULES** are rules and orders of great importance, framed by the Lord Chancellor and other judges for the regulation of criminal procedure. In Scotland the Lord Advocate (q.v.) is the principal law officer of the crown. The **CROWN-AGENT** is the solicitor to the Lord Advocate's department, and is in charge of the **CROWN OFFICE** in Edinburgh. It is through the crown-agent and the Crown Office that communications are carried on between the Lord Advocate and his deputies on the one hand and the procurators-fiscal on the other hand with regard to criminal prosecutions. All serious offences and accidents are reported to the crown-agent, who lays the report before crown counsel. The appointment of the crown-agent lies with the Lord Advocate.

**CROWN DEBTS.** See DEBT, EXTENT, EXCHEQUER. **CROWN-LANDS** are the hereditary landed property of the sovereign in right of his kingship. It is now usual for the sovereign on his accession to surrender his interest in the crown-lands for his life, in return for a civil list of a fixed amount settled on him. The crown-lands are called annexed property in Scotland, and demesne lands in England, and are of course also distinct from the private estate of the person who happens to be sovereign. They are now contracted within narrow limits, having been almost entirely granted away to subjects. The superintendence of such property as still belongs to the crown is now vested in the Commissioners of Woods, Forests, and Land Revenues (see WOODS AND FORESTS). In some British colonies unallotted ground is still referred to and legislated for as crown-land.

**CROWN CASES RESERVED** gave name to a court established in 1848 to decide points of law arising in criminal cases, and 'reserved' by the judge at the trial. This court was superseded by the Criminal Appeal Act, 1907, which created a Court of Criminal Appeal that can review any question whether of law or of fact. See APPEAL.

**Crown**, in Architecture, a species of spire or lantern, formed by converging flying-buttresses—e.g. the crowns of St Giles', Edinburgh, and King's College, Aberdeen; in England the only old crown is that of St Nicholas's Cathedral, Newcastle.

**Crown Imperial.** See FRITILLARY.

**Crown Pieces**, of the value of five shillings, were introduced into the English coinage by Henry VIII.; originally of gold, they were first struck in silver by Edward VI.; none were coined from 1861 till 1887. Austria, Denmark, Norway, and Sweden have also crowns; and the French *ecu* is so translated.

**Crown Point**, a post-village of New York, on Lake Champlain, near the site of a British fort of the same name taken by Ethan Allen in 1775.

**Crown-work**, in Fortification, is an outwork consisting of two Bastion (q.v.) fronts connected with the main work by long flanks, so that its plan resembles somewhat the outline of a crown.

**Crow's-feet.** See CALTROP.

**Crow-stone**, the top stone of the gable-end of a building. See CORBIE STEPS.

**Crowther**, SAMUEL ADJAI (1812-91), negro bishop, whose native name was Adjai, was born in Ochugu, Dahomey. He was carried off as a slave in 1819, and after having been bartered and sold more than once, was taken by a British man-of-war and landed at Sierra-Leone in 1822. Under the influence of missionary training he embraced Christianity in 1825, assuming the name of a London vicar, and was later placed in charge of a mission school. He was with the first and second Niger expeditions (1841, 1854), and visited London in 1842, when, after further training, he was ordained by the Bishop of London. Entering with enthusiasm upon his missionary labours, he was consecrated Bishop of the Niger territory in 1864. A D.D. of Oxford, he translated the Bible into the Yoruba language. See his *Life* (1888), and J. Page, *The Black Bishop* (1908).

**Croydon**, a town in Surrey, 10½ miles S. of London Bridge, yet practically a suburb of London. It lies on the edge of the chalk and plastic clay, near the Banstead Downs, at the source of the Wandle, hence its name *Croindene* (Fr., 'chalkhill') in Domesday. The archbishops of Canterbury had a palace here from the Conquest till 1757. Its Perpendicular hall (1452) and chapel (1633-63) were purchased by the Duke of Newcastle in 1887 and presented to the Sisters of the Church Extension

Association. Addington Park,  $3\frac{1}{2}$  miles ESE., was in 1807–1902 summer seat of the archbishops of Canterbury. Addiscombe House, home of the first Earl of Liverpool, was converted in 1812 into the East India Military College, but was pulled down in 1863. The fine old Perpendicular parish church was destroyed by fire in January 1867, with the exception of the tower, but was rebuilt by Sir Gilbert Scott, and retains the monument of Archbishop Sheldon, with fragments of that of Archbishop Grindal. That of Archbishop Whitgift was restored in 1888 at a cost of £600. Whitgift's Hospital (1596) is a red brick pile, restored in 1860; his grammar-school now occupies buildings of 1871, and under the same endowment is a large Whitgift middle school. A new town hall, with law-courts and free library, was opened in 1896. Croydon was one of the first towns to grapple effectually with the economical disposal of town-sewage. A system of disposing of sewage by irrigation was inaugurated in 1858. In 1868 new water-works were completed, the water, which is of great purity, being obtained from an artesian well; and a further supply has since been added. There is a suffragan bishop under Canterbury. Till the 18th century Croydon was famous for its 'colliers' or charcoal-burners; now its chief specialty is the manufacture of church clocks and carillons. There is an aerodrome for commercial and passenger traffic. The town is, however, mainly residential in character. It was made a municipal borough in 1883, a parliamentary borough in 1885 (with two members since 1918), and a county borough in 1888. Pop. (1851) 10,260; (1871) 55,652; (1921) 190,877.

**Croyland.** See CROWLAND.

**Crozet Islands,** a group in the Indian Ocean, between the Cape of Good Hope and Kerguelen, in lat.  $46^{\circ}$  S., and long.  $52^{\circ}$  E.; the largest are Possession, East, Apostle, and Hog; apart from these they are mere rocks. All are uninhabited, though shipwrecked sailors have lived for a time on them. They were visited by the *Challenger* expedition in 1873–74, but have never been adequately explored. They were annexed by France in 1913.

**Crozier.** See CROSIER, PASTORAL STAFF.

**Crucian** (*Carassius vulgaris*), a fresh-water fish, nearly related to the carp, from which it differs in the absence of barbules, in the single-rowed arrangement of the pharyngeal teeth, and in a few other minor points. It is found in numerous varieties in rivers, ponds, and lakes in Europe and Asia; and is sometimes, though rarely, caught in the Thames. The food chiefly consists of dead vegetable and animal matter. The flesh is less esteemed than that of carp. The fish spawn in May or June, and then assemble in great numbers. See CARP.

**Crucibles** (Low Lat. *crucibulum*; from the root of Old Fr. *cruche*, 'a pot') are vessels made of materials capable of being exposed to high temperatures without alteration, and used for fusing substances together, such as the materials for glass-making, or metallic ores, with various fluxes to obtain the several metals they yield. Crucibles should resist the corrosive action of the substances brought into contact with them, and are generally made of fireclay, porcelain, graphite, iron, platinum, and, for some special operations, of silver. See ASSAYING.

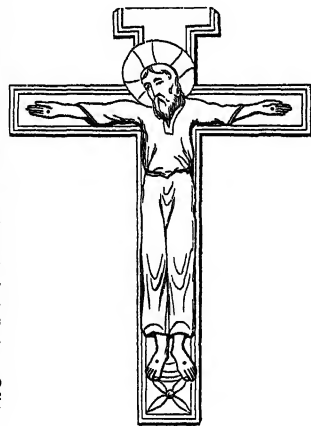

Crucible.

**Cruciferae** (Lat., 'cross-bearing,' from the X-wise position of the four petals), an important order of archichlamydeous dicotyledons, including about 1200 known species, mostly paleoarctic, and specially abundant in Europe. No order is indeed more

familiar or more widely represented; the Mustard, Shepherd's Purse, &c., are among the commonest weeds of cultivation, while the Turnip and Cabbage, the Radish and Cress, &c., are no less familiar and widespread in usefulness. As wild flowers, they are mostly inconspicuous, but the pretty Cuckoo-flower or Lady's Smock (*Cardamine pratensis*), and not a few others, might be mentioned as contributing some characteristic feature to marsh or cliff or copse; while a large number of genera are of the greatest value to the florist, for whom the exuberant masses of Iberis, Alyssum, Arabis, and Aubrietia are among the most admired resources of the rock-garden. Besides the Stocks and Wallflowers, &c., the old-fashioned Honesty and Gillyflower are among the most familiar inmates of every cottage-garden. The general character of the order is antiscorbatic and stimulating, with more or less acidity; the familiar flavour being due to the presence of a characteristic ethereal oil. Striking examples of these properties are given by the Scurvy-grass of our shores, so important to mariners in the days of long voyages and salt provisions; or more familiarly by the Common Water-cress; while a wide range of variation of flavour is presented by the flesh, rind, and leaves of the Common Turnip, especially in different varieties, soils, and seasons. A fixed oil is largely present in the seeds (see RAPE, COLZA), and the Woad Plant (*Isatis*, see WOAD) has been used from the earliest times as a source of indigo. The order was conveniently subdivided by Linnæus by the nature of its fruit as long and short podded (*Siliculosæ* and *Siliculosæ*), while later systematists have derived important characters from the mode of folding of the cotyledons within the seed. See Engler's *Pflanzenfamilien*, or other systematic work, and separate articles—e.g. CABBAGE.

**Crucifix** (Lat. *crux*, 'the cross,' and *figo*, 'I fix'), a cross with the effigy of Christ fixed to it. The principal crucifix in Catholic churches stands in the centre of the high-altar. It overtops the tapers, and is only removed to make place for the host in the service of Benediction. In well-appointed churches, the altar crucifix is generally either of gold or silver. Crucifixes are used in Lutheran churches, and in Prussia they are often made of Berlin iron. The crucifix first began to take the place of the plain cross in the time of Constantine, but it was never publicly acknowledged by the Greek Church, and did not come into general use in the East till towards the end of the 8th century. It was not till the Carlovingian age that it became general in the Latin Church. On the earlier crucifixes, Christ is represented as alive, with open eyes, and generally clad, and fastened with four nails. On later ones he is represented as dead, naked, except for a cloth round the loins, and fastened with three nails—i.e. the two feet pierced by a single nail. See CROSS.

**Cruden,** ALEXANDER, born at Aberdeen, 31st May 1701, from the grammar-school passed to

Marischal College, where he took his M.A., but, having shown symptoms of insanity, was for a short time placed in confinement. On his release he left Aberdeen, and, after spending ten years as a tutor, in 1732 established himself as a bookseller in London. In 1737 appeared his *Complete Concordance of the Holy Scriptures*, a really admirable work. It was dedicated to Queen Caroline, who graciously promised to 'remember him,' but unfortunately died a few days later. Cruden now relapsed into insanity, and for ten weeks was kept in a mad-house, as again for a fortnight in 1753. Earning meanwhile his livelihood as a press-reader, he assumed the title of 'Alexander the Corrector,' and in 1755 began to go through the country, reproving by voice and pen the nation's sins of Sabbath-breaking and profanity. But many a good and kindly action was interwoven with his crack-brained courtships, his dreams of knighthood and a seat in parliament. He was just back from a visit to his native city, when he died at his prayers in his Islington lodgings, 1st November 1770. See the *Life* by A. Chalmers, prefixed since 1824 to many of the numerous editions of the *Concordance*. See CONCORDANCE.

**Cruelty.** See ANIMALS (CRUELTY TO), CHILDREN.

**Cruikshank, GEORGE**, one of the most gifted of English pictorial satirists, was born in London, September 27, 1792, the son of Isaac Cruikshank, who, as well as his eldest son, Isaac Robert Cruikshank, was also known as a caricaturist. Cruikshank at first thought of the sea as a profession; but some of his sketches having come under the notice of a publisher, he was induced to engage in the illustration of children's books and songs. A publication, *The Scourge* (1811-16), afforded scope for the display of his satiric genius, and from that time forth he continued to pursue with remarkable success this his true vein. His illustrations for Hone's political squibs and pamphlets, and especially those dealing with the Queen Caroline trial, attracted much attention, and sent some of them through no less than fifty editions. But in the exquisite series of coloured etchings contributed to the *Humorist* (1819-21), and in the etchings to the *Points of Humour* (1823-24), did his true artistic power begin to be visible. This second, and in many ways finest, period of his art, represented by these works, culminated in the etchings to *Peter Schlemihl* (1823), and to Grimm's *German Popular Stories* (1824-26), which in the simple directness and effectiveness of their execution, and in their fertile and uncumbered fancy, rank as the artist's masterpieces. The latter series, now extremely scarce, was reproduced in 1868, with a laudatory preface from the pen of Mr Ruskin. Similar in artistic aims and method are the spirited little woodcuts contributed to the *Italian Tales* (1824), *Mornings at Bow Street* (1824-27), and Clark's *Three Courses and a Dessert* (1830); and the plates to Scott's *Demonology and Witchcraft* (1830) may be regarded as the last examples of his earlier and simpler method as an etcher. His numerous plates in *Bentley's Miscellany* mark a third period of his art, in which he aimed at greater elaboration and completeness, introducing more complex effects of chiar-oscuro, and frequently attaining great power of tragic design. The finest of these are the great series to Dickens's *Oliver Twist*, and to Ainsworth's *Jack Sheppard* in *Bentley's Miscellany*, and *The Tower of London*, and in the same class are to be ranked the plates to *Windsor Castle*, and *The Miser's Daughter*, of which, as of *Oliver Twist*, he thirty years afterwards claimed the chief authorship. Among the best productions of his later years are the large

and elaborate etchings to Brough's *Life of Sir John Falstaff*, published in 1858. His last illustration was the frontispiece to Mrs Blewitt's *The Rose and the Lily* (1877), 'Designed and etched by George Cruikshank, aged eighty-three, 1875.' As a water-colourist he left work marked by considerable skill and delicacy. In his late years he devoted himself to oil-painting, and in this province showed perhaps more humour, fervour, and inventive ability than artistic power. His most important picture was 'Worship of Bacchus' (1862), which has been engraved partly by his own hand, a vigorous and earnest protest against the evils of drunkenness; and to the cause of temperance he also devoted many of his designs, especially the tragic and powerful series of *The Bottle* (1847), which, reproduced by glyptography, attained an immense circulation. He died 1st February 1878. There are excellent collections of his works in the print-room, British Museum, and the South Kensington Museum. The last named, presented in 1884 by the artist's widow, numbers 3481 items. See G. W. Reid's *Catalogue* (3 vols. 1871), and Lives by Bates (2d ed. 1879), Jerrold (2d ed. 1883), and Stephens (1891); and Marchmont's *The Three Cruikshanks* (1897).

**Cruiser**, formerly an armed ship employed to protect commerce or capture enemies' ships. See PRIVATEER, FRIGATE; also NAVY.

**Crummock Water**, adjoins Buttermere (q.v.).

**Crusades** is the name given to the religious wars carried on during the middle ages between the Christian nations of the West and the Mohammedans. In time, however, the name came to be applied to any military expedition against heretics or enemies of the pope. The first of the regular crusades was undertaken simply to vindicate the right of Christian pilgrims to visit the Holy Sepulchre. On the conquest of Palestine, however, the object of the crusades changed, or at least enlarged, and the efforts of the subsequent crusaders were directed to the recovery of the whole land from the Saracens, who had repossessed themselves of it. From an early period in the history of the church, it was considered a pious act to make a pilgrimage to the Holy Sepulchre, and to visit the various spots which the Saviour had consecrated by his presence. When Palestine was conquered by the Arabs in the 7th century, that fierce but generous people respected the religious spirit of the pilgrims, and allowed them to build a church and a hospital in Jerusalem. Under the Fatimides of Egypt, who conquered Syria about 980 A.D., the position both of the native Christian residents and of the pilgrims became less favourable; but the subjugation of the country in 1065 by brutal hordes of Seljuk Turks from the Caucasus rendered it intolerable. These barbarians, but recently converted to Mohammedanism, were nearly as ignorant of the Koran as of the Scriptures. They hardly knew their fellow-religionists, and are said to have wreaked their vengeance on the Mussulmans of Syria as well as on the Christians. The news of their atrocities produced a deep sensation over the whole of Christendom. The first to take alarm were, naturally enough, the Byzantine monarchs. In 1073 the Greek emperor, Michael VII., sent to supplicate the assistance of the great Pope Gregory VII. against the Turks, accompanying his petition with many expressions of profound respect for His Holiness and the Latin Church. Gregory—who beheld in the supplication of Michael a grand opportunity for realising the Catholic unity of Christendom—cordially responded; but circumstances prevented him from ever carrying the vast designs which he entertained into execution, and the idea of a crusade died gradually away. It was, however,

revived by his successor Urban II., an able and humane man, to whom Alexius Comnenus appealed, as had Michael to Gregory. But Urban thought more of Jerusalem than of the reconquest of Asia Minor. Two councils were held in 1095. At the second, held at Clermont, in France, a crusade was definitely resolved on. The pope himself delivered a stirring address to a vast multitude of clergy and laymen, and as he proceeded the pent-up emotions of the crowd burst forth, and cries of *Deus vult* ('God wills it') rose simultaneously from the whole audience. 'This tumultuous cry,' says Hallam, 'which broke from the heart and lips of the assembly at Clermont, affords at once the most obvious and most certain explanation of the leading principle of the crusades.' These words, *Deus vult*, were made by Urban the war-cry of the enterprise, and every one that embarked in it wore, as a badge, the sign of the cross; hence the name *Crusade* (Lat. *cruaz*, 'a cross'). Peter the Hermit, who used to be thought the originator of the movement, was only one of the most notable of many preachers who spread the enthusiasm throughout Christendom. They traversed Europe, preaching everywhere to crowds in the open air, and producing the most extraordinary fervour by their impassioned descriptions of how pilgrims were murdered, robbed, or beaten; how shrines and holy places were desecrated; and how nothing but greed restrained the ruffian Turks (who made the Christians pay heavy taxes for their visits to Jerusalem) from destroying the Holy Sepulchre, and extirpating every vestige of Christianity in the land.

*First Crusade.*—From all parts of Europe thousands upon thousands hurried at the summons of the pope to engage in the holy war. 'The most distant islands and savage countries,' says William of Malmesbury, 'were inspired with this ardent passion. The Welshman left his hunting, the Scotchman his fellowship with vermin, the Dane his drinking-party, the Norwegian his raw fish.' It is said that in the spring of 1096 not less than 6,000,000 souls were in motion towards Palestine. This, however, must be a huge exaggeration. What we do know positively is, that previous to the setting out of the great hosts of European chivalry, four or five armies—if disorderly multitudes deserve that name—amounting in all to 275,000 persons, had departed for Palestine. The first consisted of 20,000 foot, and was commanded by a Burgundian gentleman, Walter the Penniless. It marched through Hungary, but was cut to pieces by the natives of Bulgaria, only a few, among whom was Walter himself, escaping to Constantinople. The second, consisting of 40,000 men, women, and children, was led by Peter the Hermit. It followed the same route as its predecessor, and reached Constantinople greatly reduced in numbers. Here the two united, crossed the Bosphorus, and were utterly defeated by the Turks at Nicæa, the capital of Bithynia. A third expedition of a similar kind, composed of 15,000 Germans, led by a priest named Gottschalk, was dispersed with terrible slaughter in Hungary; which also proved the grave of the fourth, a horde consisting of about 200,000 wretches from France, England, Flanders, and Lorraine, who had swept along through Germany, committing horrible ravages, especially against the Jews, whom they murdered without mercy. Now, however, the real crusaders made their appearance: the gentry, the yeomanry, and the serfs of feudal Europe, under chiefs of the first rank and renown. In this, the most successful of the crusades, neither the emperor nor any of the kings of the West participated; and to this circumstance was doubtless due its more fortunate termination. Six armies appeared in the field, marching separately, and at considerable

intervals of time. Their respective leaders were Godfrey of Bouillon, Duke of Lorraine; Hugh the Great, Count of Vermandois, and brother of Philippe, king of France; Robert Curthose, Duke of Normandy, the son of William the Conqueror; Count Robert of Flanders; Bohemond, Prince of Tarentum, son of the famous Guiscard, under whom was Tancred, the favourite hero of all the historians of the crusade; and Count Raymond of Toulouse. The place of rendezvous was Constantinople. The Greek emperor, Alexius, afraid that so magnificent a host—there were said to be 600,000 men, exclusive of women and priests—might be induced to conquer lands for *themselves*, cajoled all the leaders, excepting Tancred and Count Raymond, into solemnly acknowledging themselves his liegemen as long as they remained in his territory. After some time spent in feasting, the crusaders crossed into Asia Minor, accompanied by the unfortunate Peter the Hermit. Here their first step was the siege and capture of Nicæa, the capital of Sultan Soliman, in June 1097. This monarch was also defeated by Bohemond, Tancred, and Godfrey, at Dorylæum. Baldwin, brother of Godfrey, now crossed into Mesopotamia, where he obtained the principality of Edessa. After some time, the crusaders reached Syria, and laid siege to Antioch. For seven months the city held out, and the ranks of the besiegers were fearfully thinned by famine and disease. Many even brave warriors lost heart, and began to desert. Melancholy to relate, among the deserters was the poor enthusiast who had inspired the enterprise. Peter was actually several miles on his way home when he was overtaken by the soldiers of Tancred, and brought back to undergo a public reprimand. At length, on the 3d of June 1098, Antioch was taken, and the inhabitants were massacred by the infuriated crusaders, who were in their turn besieged by an army of 200,000 Mohammedans sent by the Persian sultan. Once more famine and pestilence did their deadly work. Multitudes also deserted, and escaping over the walls, carried the news of the sad condition of the Christians back to Europe. But again victory crowned the efforts of the besieged. On the 28th June 1098 the Mohammedans were utterly routed, and the way to Jerusalem opened. It was on a bright summer morning (1099) that 20,000 to 40,000 crusaders, the miserable remnant of that vast array which two years before had laid siege to Nicæa, obtained their first glimpse of Jerusalem. On the 15th of July, after a siege of rather more than five weeks, the grand object of the expedition was realised. Jerusalem was delivered from the hands of the infidel. As on the occasion of all the triumphs of these first crusaders, a horrible massacre ensued. Religious enthusiasm, evoking the intensest and most strangely mingled passions, naturally led to these excesses on the part of men reared in the fiercest times of feudalism. Godfrey of Bouillon was unanimously elected king of Jerusalem. Unlike his successors, he refused the title royal. His kingdom, at first comprising little more than the mere city of Jerusalem, was gradually extended by conquest until it included the whole of Palestine. A language resembling Norman French was established, a code of feudal laws drawn up—Jerusalem was erected into a patriarchate, and Bethlehem into a bishopric. The best part of Asia Minor was restored to the Greek empire, while Bohemond became Prince of Antioch. For nearly fifty years, the three Latin principalities or kingdoms of the East—Edessa, Antioch, and Jerusalem—not only maintained themselves against the attacks of the Mohammedans of Egypt and Syria, but greatly increased in size, power, and wealth. At Jeru-

salem were founded the two famous orders of the Knights Hospitallers of St John and the Knights Templars.

*Second Crusade.*—In 1144 the principality of Edessa was conquered by the Emir of Mosul, and the Christians slaughtered. His son, Nureddin, advanced to destroy the Latin kingdoms of Syria and Palestine. Europe once more trembled with excitement. A second crusade was preached by the famous St Bernard, abbot of Clairvaux, in Champagne; and early in 1147 two enormous armies, under the command of Louis VII., king of France, and Conrad III., emperor of Germany, marched for the Holy Land. Their united numbers were estimated at 1,200,000 fighting-men. The expedition, nevertheless, proved a total failure. The Greek emperor, Manuel Comnenus, was hostile; and through the treachery of his emissaries, the army of Conrad was all but destroyed by the Turks near Iconium, while that of Louis was wrecked in the defiles of the Pisidian Mountains. After a vain attempt to reduce Damascus, the relics of this mighty host returned to Europe.

*Third Crusade.*—The death-blow, however, to the kingdom of Jerusalem, and the power of the crusaders, was given, not by Nureddin, but by Salah-Eddin, commonly called Saladin, a young Kurdish chief, who had made himself sultan of Egypt, and who aspired to the suzerainty of the Mohammedan world. He invaded Palestine, took town after town, and finally, in October 1187, compelled Jerusalem itself to capitulate, after a siege of fourteen days. The news of this led to a third crusade, the chiefs of which were Frederick I. (Barbarossa), emperor of Germany; Philippe Auguste, king of France, and Richard Cœur-de-Lion, king of England. Barbarossa took the field first in the spring of 1189, but was thrown from his horse and drowned in crossing the Salef. His army, much reduced, joined the forces of the other two monarchs before Acre, which important city was immediately besieged. In vain did Saladin attempt to relieve the defenders; and after a beleaguering of twenty-three months, the place surrendered. But the crusaders were not united among themselves. Philippe soon after returned to France; and Richard, after accomplishing prodigies of valour, which excited the admiration of the Saracens, concluded a treaty with Saladin, by which 'the people of the West were to be at liberty to make pilgrimages to Jerusalem, exempt from the taxes which the Saracen princes had in former times imposed.' This, as has been previously noticed, was all that had been claimed by the first crusaders. On the 25th of October 1192, Richard set sail for Europe.

*Fourth Crusade.*—Crusading unfortunately now became a constituent of the papal policy; and in 1203 a fourth expedition was determined upon by Pope Innocent III., although the condition of the Christians was by no means such as to call for it. It assembled at Venice; but how entirely secular crusading had become, will be seen from the fact that the army never went to Palestine at all, but preferred to take possession of the Byzantine empire. The leader of this host of *pseudo-crusaders*, Baldwin, Count of Flanders, was seated on the throne of the East in 1204, and thus founded the Latin empire of Constantinople. Nothing was achieved for the recovery of Jerusalem, but Innocent had his reward in the temporary supremacy of the papal see over the Eastern Church. See BYZANTINE EMPIRE, VENICE.

*Fifth Crusade.*—This was commanded by Frederick II., emperor of Germany. It began in 1228, and terminated in a treaty between that monarch and the sultan of Egypt, by which Jerusalem (with

the exception of the Mosque of Omar), Jaffa, Beth-lehem, and Nazareth were ceded to Frederick, who, after being crowned king of Jerusalem, returned to Europe, leaving his new possessions in a state of tranquillity. Frederick, however, who had been excommunicated by Gregory IX. for his tardiness in embarking in this crusade, was denounced in the most violent language by the same pope for having thus made terms with the infidel.

*Sixth Crusade.*—In 1244 the Khorasmians, driven from Tartary by Genghis Khan, burst into Syria, and made themselves masters of Jerusalem. This was made, by Pope Innocent IV., the occasion for another crusade; and in 1249 Louis IX. (St Louis) of France headed an expedition against Egypt, which was now regarded as the key of the Holy Land. The expedition was an utter failure. Louis was defeated and taken prisoner by the sultan, and obtained his liberty only on the payment of a heavy ransom.

*Seventh Crusade.*—This also was primarily undertaken by St Louis, but he having died at Tunis (where he had gone in the hope of baptising its king) in 1270, on his way to Palestine, Prince Edward of England, afterwards Edward I., who had originally intended to place himself under the command of St Louis, marched direct for Palestine, where his rank and reputation in arms gathered round him all who were willing to fight for the cross. Nothing of consequence, however, was accomplished; and Edward soon returned to England, the last of the crusaders. Acre and Tripoli still continued in the possession of the Christians, and were defended for some time by the Templars and other military knights; but in 1289 Tripoli capitulated, and two years later Acre, and the knights were glad to quit the country and disperse themselves over Europe, leaving Palestine in the undisturbed possession of the Saracens.

Though conventionally the crusades are numbered, their distinctness cannot be maintained. The Latin kingdom and the Latin principalities, with their resident Latin population, small though it was, gave them continuity; and small bodies of crusaders were constantly coming and going. Of pseudo-crusades, three deserve notice as productive of important results. Firstly, in 1209, there was that against the Albigenses (q.v.). Secondly, on the principle that it was binding on the servants of the church to do battle with all outside its pale, in 1230 the Teutonic knights were called on by Gregory IX. to undertake a crusade against the heathen Prussians on the shores of the Baltic. The result was the complete subjugation of the Prussians, and the establishment in their country of the Teutonic military order till its extinction at the battle of Tannenberg in 1410. Thirdly, in 1262 Urban IV., jealous of the growing power of Manfred, king of Sicily, son of the Emperor Frederick II., offered Manfred's crown to Charles of Anjou, brother of St Louis of France, and gave to this dispossession the name of a crusade. A protracted war ensued, which resulted in the House of Anjou gaining the kingdom of Naples, and the House of Aragon the kingdom of Sicily. The terrible wars of the 16th century between France and Spain for supremacy in Italy were the direct consequence of this pseudo-crusade.

*Effects of the Crusades.*—While we cannot help deploring the enormous expenditure of human life which the crusades occasioned, it is impossible to overlook the fact that they indirectly exercised a most beneficial influence on modern society. They secured for humanity certain advantages which it is difficult to see could have been otherwise obtained. Guizot, in his *Lectures on European Civilisation*, endeavoured to show their design and function in the destinies of Christendom. 'To the

first chroniclers,' he says, 'and consequently to the first crusaders, of whom they are but the expression, Mohammedans are objects only of hatred: it is evident that those who speak of them do not know them. The historians of the later crusades speak quite differently: it is clear that they look upon them no longer as monsters; that they have to a certain extent entered into their ideas; that they have lived with them; and that relations, and even a sort of sympathy, have been established between them.' Thus the minds of both, but particularly of the crusaders, were partly delivered from those prejudices which are the offspring of ignorance. 'A step was taken towards the enfranchisement of the human mind.' Secondly, the crusaders were brought into contact with two civilisations richer and more advanced than their own—the Greek and the Saracenic; and it is beyond all question that they were mightily struck with the wealth and comparative refinement of the East. Thirdly, the close relationship between the chief laymen of the West and the church, occasioned by the crusades, enabled the former 'to inspect more narrowly the policy and motives of the papal court.' The result was very disastrous to that spirit of veneration and belief on which the church lives, and in many cases an extraordinary freedom of judgment and hardihood of opinion were induced—such as Europe had never before dreamed of. The immediate results of the crusades, however, went altogether to strengthen the power of the church. Through their means the popes found an easy method of ridding themselves of refractory monarchs; and by the exorbitant taxes levied in the name of the cross they practically rendered all the kingdoms of the West their tributaries. Fourthly, great social changes were brought about. A commerce between the East and West sprang up, and towns—the early homes of liberty in Europe—began to grow great and powerful. The crusades, indeed, 'gave maritime commerce the strongest impulse it had ever received.'

**Crusca**, ACCADEMIA DELLA. See ACADEMY, DELLA CRUSCAN SCHOOL.

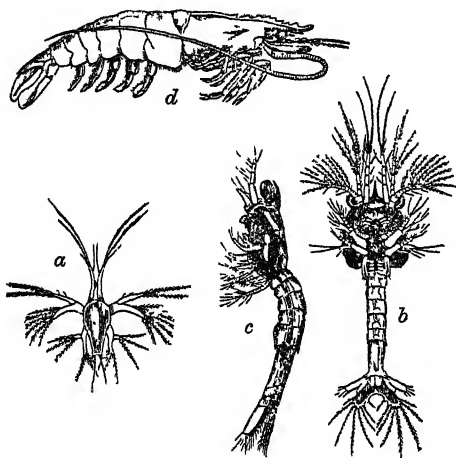

**Crusenstolpe**, MAGNUS JAKOB, Swedish political writer, was born at Jönköping, 11th March 1795. He wrote novels, elaborate historical works, pamphlets, and contributed to the newspapers. His *Ställningar och Förhållanden*, carried on from 1838 till 1865, applied vigorous and unsparing criticism to the questions and persons of the day. His bitter opposition to government cost him three years' imprisonment (1838–41). He died 18th January 1865.

**Crustacea**, a large and important class of Arthropod animals, including crabs, lobsters, shrimps, sand-hoppers, wood-lice, water-fleas, barnacles, acorn-shells, &c. The class contains such variety of structure that general characters are hard to find. They are almost all aquatic, but a few (e.g. wood-lice and land-crabs) are terrestrial. The majority are marine, but great numbers inhabit fresh water. The form of the body is very variable, as may be seen by contrasting crab and barnacle. A head with five pairs of appendages, a limb-bearing thorax more or less united to the former, and a segmented abdomen with or without

limbs, are very generally distinguishable. The segmentation is never developed in the Ostracod water-fleas, and is often lost in degenerate forms. By the development of shields (Apus), bivalve shells (water-fleas), and mantles (Cirripedes), the real form is often obscured. As to appendages, the head usually bears two pairs of antennæ, a pair of mandibles, and two pairs of maxillæ; the thorax is always limb-bearing except in utter degeneracy; and the abdomen of the majority also carries appendages. The typical form of limb, on which so many changes are rung, consists of a basal piece and two more or less jointed forks. The cuticle varies greatly in degree of firmness, but is always chitinous (see CHITIN) and often much calcified. Glands open on various parts of the surface, and may be of use for preliminary digestion, for egg attachment, for mooring the animal, &c. The colouring of the body is often very brilliant and beautiful (see PIGMENT). It is sometimes like that of the surroundings, and is occasionally associated with sexuality. The power of colour-change is also not uncommon. Sapphirina is said to rival the humming-bird in its splendour. While the nervous system in general retains the Arthropod characteristics, the ventral ganglia are often concentrated (as in crabs). The majority possess compound eyes, which in one large division are stalked. Eyes are absent in some subterranean forms, and are lost during the development of Cirripedia (q.v.) and many parasites. In the Euphausiidae there are very numerous eye-like structures or luminous organs over the body. Smelling hairs usually occur on the first antennæ, and auditory hairs have been frequently observed, usually more or less inclosed in sacs. The alimentary system, which consists of fore, mid, and hind gut, is usually simple, except as regards the hard masticating parts often developed on the cuticle of the anterior portion. In some parasitic forms the entire system degenerates. The body-cavity is usually a good deal filled up by the muscles and viscera; it contains the blood-fluid, which is occasionally faintly coloured with hæmoglobin, tetronerythrin, and other pigments, and includes amoeboid elements. A heart is usually present in the thoracic region, and is often inclosed in a special part of the body-cavity—the pericardium. In higher forms the blood passes by distinct arteries to the bodies, is gathered up in venous spaces and sinuses, is purified in the gills, and returns to the pericardial sac and heart. The respiratory system is typically represented by distinct gills variously attached; in many cases water flows in and out at the anus, and probably effects an anal respiration; in many lower forms the blood is simply purified by being exposed under the skin. The excretory system is never very marked. The green glands of higher forms, the shell-glands of Phyllopods and Copepods, and certain other structures, are excretory. The reproductive system presents many variations. The sexes are usually separate, but most Cirripedes are hermaphrodite. 'In the Cymothoidæ (Isopoda) the sexual organ of the young animal is male—of the old, female—in function.' The glands are usually thoracic, and the ducts double. Some of the appendages are often modified for copulation or egg-retaining. The spermatozoa are peculiar in being usually non-motile. The eggs are in most cases carried about by the female, but are occasionally laid on water-plants, &c., or in the water. According to Bates, *Podocerus capillatus* builds a nest of interlaced seaweed. Parthenogenesis (q.v.) has been observed in some of the lower forms. 'Complemental' males occur among the hermaphrodite Barnacles and Acorn-shells (q.v.).

*Life-history*.—The development of Crustaceans is usually indirect—that is to say, the newly-

hatched young is unlike, often very unlike, its parent. Even when there is no metamorphosis after hatching, traces of transformation, as opposed to continuous development, are sometimes to be detected in the earlier history while the embryo is still within the egg-case. (a) The crayfish (*Astacus*) has a very much abbreviated life-history, for the newly-hatched form is almost quite like the adult. (b) The newly-hatched lobster (*Homarus*), however, begins life a little further back, in what is known as the *Mysis* stage, in which the thorax bears two-branched swimming appendages. (c) Most other higher Crustaceans (e.g. crabs) begin at a still lower level, in what is called the *Zoea* stage, with a short unjointed thorax and a segmented abdomen without limbs. (d) The

Development of a Prawn (*Penaeus*):  
a, Nauplius; b, Zoea; c, Mysis; d, adult.

Decapod *Penaeus*, a shrimp-like creature, has its life-history still more drawn out. It quits the egg as a *Nauplius*, an unsegmented larva with three pairs of appendages, the first unforked, the other two pairs double-branched. These correspond to the first three appendages of the adult. The median eye is also a distinctive feature in the Nauplius larva. The *Penaeus* Nauplius has with successive moults first to become a *Zoea*, and then a *Mysis*, and then an adult. It is as a Nauplius that the majority of lower Crustaceans leave the egg, but then they do not climb so high. To understand the circuitous life-history of a form like *Penaeus*, we have to note that it begins in the Nauplius stage, at the level of the lowest Crustaceans, and gradually climbs through a series of higher and higher stages, each of which is represented permanently by some division of Crustaceans which have not risen higher. If the various grades from Nauplius up to Decapod adult represent successive historic levels, now exemplified in the classification of Crustaceans by those which were left behind at each lift, what the *Penaeus* does is to recapitulate in its individual life-history the historic evolution of the class. This idea has been beautifully applied to Crustaceans in Fritz Müller's *Facts for Darwin*. The various grades of Nauplius, *Zoea*, *Mysis*, and adult *Penaeus* (overlooking intermediate ones) may be compared to stations which mark the gradual extension of the Crustacean line of advance. *Penaeus* has to travel along the rails laid down by the ancestral history, and has to stop for variable periods at the successive stations between the starting-point and the terminus. Crabs skip over the Nauplius station, and like most other Decapods

start at the *Zoea* point; lobsters abbreviate still further, and begin as *Mysis* forms; the crayfish has found the shortest cut of all. Some of the lower Crustaceans never get far past the Nauplius stage, while others remain practically on the *Zoea* grade. The life-histories of Crustaceans vividly illustrate how the individual life-history is a rehearsal of the historic evolution of the kind, or more technically, how ontogeny recapitulates phylogeny.

*Habit of Life*.—The acorn-shells fastened to the rocks, wafting in their food by their curled feet; the barnacles moored to floating logs and ship-bottoms; such extremes of parasitism as are illustrated by *Sacculina* on hermit-crabs; the hermit-crabs themselves, stealing the shells of *Gasteropods*, or entering into partnership with sea-anemones; the thousand minute and active water-fleas; the wood-lice, quite terrestrial; the brine-shrimps in the salt-pools; the fresh-water crayfish; the giant marine lobsters; the land-crabs, habituated to inland life, sufficiently suggest how varied are the habits of Crustaceans. Some Crustaceans form masking shelters for themselves out of Tunicates, or get covered over by a concealing growth of seaweed, sponge, hydroids, &c. A few forms are known to make a stridulating noise. The general intelligence of the class is probably considerable (see CRAB). On the whole the members of this class are active animals, but on each side of the medium activity of the majority there are extremes. Thus, not a few active marine forms are phosphorescent, while parasitism (to the extent of some 700 species) occurs in most of the subdivisions. Many of the parasites are very striking in the contrast between the free-swimming young and the *ne plus ultra* of degeneracy in the adults (see DEGENERATION, PARASITISM). Some of the interesting cases of Commensalism (q.v.) have been referred to under that title; while some of the external parasites show in the castration, &c. which they effect on their hosts, how real in such cases is the direct influence of the animate Environment (q.v.). The diet of Crustaceans is very varied; the majority are carnivorous and aggressive; many feed on dead creatures and organic debris in the water; others depend largely upon plants. They often lose limbs in fighting or otherwise, and have the power of replacing what they have lost.

*Classification*.—There are two sub-classes—Entomostraca and Malacostraca. The Entomostraca are usually small, with very diverse number of segments and appendages, with the larva generally hatched as a nauplius, with an excretory organ associated with the second maxillæ, and with no gastric mill. They include Phyllopods, e.g. Brine-shrimps, *Apus*, *Daphnia*; Ostracods, e.g. *Cypris* (fresh-water) and *Cypridina* (marine); Copepods (common water-fleas and fish-lice); and Cirripedes (Barnacles and Acorn-shells). The Malacostraca are usually larger and more complex, with nineteen segments and pairs of appendages (except in *Nebalia* and its relatives), with the larva usually higher than a nauplius, with the excretory organ usually associated with the antennæ, and often with a gastric mill. They include some primitive types, *Nebalia* and *Anaspidæ*, and a number of orders, e.g. Schizopods, Amphipods, Isopods, Decapods.

*Distribution in Space and Time*.—(a) Deep-sea forms are very abundant, and often remarkable 'for their colossal size, their bizarre forms, and brilliant red colouring.' Blind species are known to occur in the depths, and others are brilliantly phosphorescent. (b) Pelagic surface Crustaceans (especially Schizopods and Entomostraca) are very abundant, and often form a large part of the food of fishes. They are often beautifully transparent, and hardly to be seen in the water. Less

frequently they are brilliantly coloured (as in Sapphirina) or phosphorescent. Some of them are remarkable for their large eyes. One Amphipod Crustacean presents a curious mimicry of a Medusoid form. Decapods are most abundant in the warmer waters. (c) Crustaceans form an important part of the relatively sparse and uniform fauna of lakes. They occur both on the surface and at the bottom, the latter being generally more sluggish. The surface forms, at any rate, are usually perfectly transparent with the exception of the eye. (d) The catalogue of terrestrial Crustaceans, which includes species of Amphipods, Isopods, and Decapods, is relatively a very short one.

The Crustacea date back to Cambrian times, but the highest forms (Decapods) were not firmly established till the Tertiary period. Some 800 fossil species, as against over 5000 living forms, are known. Some of the genera—e.g. *Estheria*—from the Devonian, are marvellously persistent, and survive from ancient epochs as still very successful and widely distributed forms. The most primitive Crustaceans are the Phyllopods—e.g. *Apus*—and it is probable that *Nebalia* and *Anaspides* give us trustworthy hints as to the ancestors of the higher Malacostraca.

**Economic Importance.**—Crabs, lobsters, crayfish, shrimps, prawns, &c. form part of our food-supply. Others are indirectly useful as important parts of the food of herrings and other fishes. Many are doubtless useful in purifying the water from organic débris, while others are the hosts of important parasites—e.g. the Cyclops species, which contains the young stages of the Guinea-worm (q.v.).

See ACORN-SHELLS, BARNACLE, BRINE-SHRIMP, CIRRI-PEDIA, COPEPODA, CRAB, CRAYFISH, CYPRIS, CYCLOPS, LOBSTER, PRAWN, SHRIMP, WATER-FLEA, &c.; also COMMENSALISM, PARASITISM, PARTHENOGENESIS, &c., and references under above articles. For further details, consult Smith and Weldon in the *Cambridge Natural History*, Calman, *Life of Crustacea* (1911), and *Crustacea* in Lankester's *Treatise of Zoology*: Sedgwick, *Student's Text-book of Zoology*, vol. iii.; also Baird, *British Entomostraca* (Ray Soc. 1850); Balfour's *Embryology*, Bell, *British Stalk-eyed Crustacea* (Lond. 1856); Challenger Reports (several); Claus, *Genealogy of Crustacea* (1876); Dana, *Crustacea of U.S. Exploring Expedition* (Phila 1852); Gerstaecker in Bronn's *Thierreich*; Huxley's *Crayfish* (1881); Milne-Edwards, *Histoire Naturelle des Crustacés* (Paris, 1834-40); the Monographs of the Naples Station (several); F. Müller, *Facts for Darwin* (1869); Sars, *Fresh-water Crustacea of Norway* (Christiania, 1867); Spence Bate and Westwood, *British Sessile-eyed Crustacea* (1863-68); Stebbing, *A History of Crustacea* (1893).

**Crutched Friars** (M.E. *crouchen*, 'to cross'), or CROISIERS (Fr. *croix*, 'cross'), an order of friars, carrying in the hand a staff surmounted by a cross. They came to England in the 13th century, and had monasteries in London (still giving name to a street), Oxford, and Reigate.

**Crutwell**, CHARLES THOMAS, literary historian, was born in London, 30th July 1847. He was educated at Merchant Taylors' School and at St John's College, Oxford. He held various benefices in the Church of England, and died at Ewelme, near Wallingford, 4th April 1911. His works include *A History of Roman Literature* (1877) and *The Saxon Church and the Norman Conquest* (1909).

**Cruvellhier**, JEAN (1791-1874), physician, born at Limoges, became professor of Pathology at Montpellier in 1824, and of Pathological Anatomy in Paris in 1836. Besides his great work, *Anatomie Pathologique du Corps Humain* (2 vols. 1828-42), he published other works on anatomy, which were for long the most valuable French contributions to their subject, and also a *Life of Dupuytren* (1840).

**Cruvell**, SOPHIE, German soprano singer, originally named Crüwell, was born in Westphalia,

12th March 1826. She studied in Paris, made her début in Venice (1847), and retired from the operatic stage on her marriage with Comte Vigier in 1856.

**Cruz**, JUAN DE LA, was the name assumed on entering the Carmelite Order (1563) by the Spanish poet and mystic, Juan de Yepis y Álvarez, born at Fontiveros in 1542. He associated himself with Santa Teresa's movement for the reformation of the order, and in consequence suffered persecution and imprisonment till his death at Ubeda in 1591. He was canonised in 1726. His works, printed in 1580, have been repeatedly reprinted and translated.

**Crwth** (pronounce the *w* as French *u*), an old Welsh stringed instrument. Four of its six strings were played with a bow, the other two being twitched by the thumb.

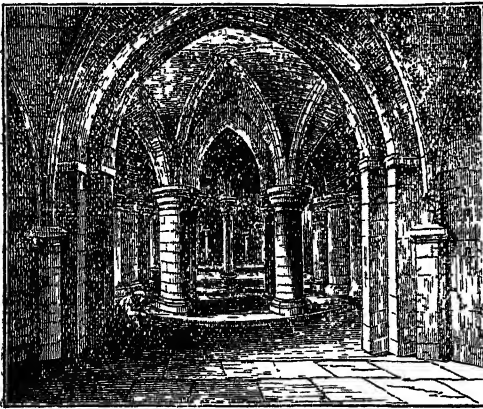

**Cryolite**, a mineral which exists in great abundance on the coast of Greenland. It consists mainly of a fluoride of aluminium in combination with Fluoride of Sodium,  $6\text{NaF} \cdot \text{Al}_2\text{F}_6$ . The metal Aluminium (q.v.) was formerly largely obtained from it, but it is now most important as a source of alum and of soda bicarbonate; much of it, also, is melted and made into a kind of glass.

**Cryophorus** (Gr. *kryōs*, 'cold,' and *pherō*, 'I carry') is an instrument consisting of a glass tube with a bulb at both ends, used for showing the diminution of temperature in water by evaporation. In constructing it the whole of the air is extracted, leaving practically a vacuum inside. A little water is present in one of the bulbs, and when the second bulb, containing only water-vapour, is placed in a freezing mixture, the vapour condenses, which causes more vapour to rise from the water in the first bulb. The result of this vaporation from the first bulb is the abstraction of much heat, and ultimately the remaining water passes into a frozen state.

**Crypt** (Gr. *kryptō*, 'I hide'). In the early days of persecution the Christians were accustomed for security to worship in the catacombs or crypts where they buried their dead (see CATACOMBS). When persecution ceased, this custom led to the erection of churches over the graves of martyrs and saints; but at a later date the bodies of the saints were transferred to chambers, constructed to resemble the catacombs, under the sanctuary or altar of the new churches, in order to add to their sanctity. These crypts and their sacred shrines were visited by numerous pilgrims, and were frequently constructed for the accommodation of the devotees, of sufficient size to admit a number at a time, who descended by one stair, and ascended by another. In other cases the crypts were so placed that the shrine of the saint could be seen from the aisles of the choir, the floor of which was necessarily raised considerably above the level of the nave. Crypts of these kinds were usual in the early centuries, and many examples of them have been preserved in Italy and France, even where the churches over them have been rebuilt. The crypt of the Circular church of St Bénigne at Dijon was one of the largest. There a great circular aperture in the centre of the floor of the upper church enabled a very large congregation of pilgrims, including those in the crypt, to see the shrine of the saint, and witness any ceremony taking place there.

After the 13th century crypts were not so much in use. The great cathedrals were regarded as much in the light of civil as of ecclesiastical edifices, and the floor of the choir was brought down to the level of the rest of the building. It sometimes happened that owing to the slope of the site considerable underbuilding was required under the choir, in which case an under church was constructed, which was called by the old name of the

crypt, and was generally used for sepulchral purposes. The crypt of Canterbury is one of the finest of this kind. The crypt of Glasgow Cathedral is

Crypt, Canterbury Cathedral.

also a very beautiful example, the vaulting over the shrine of St Mungo being pointed out by Sir Gilbert Scott in his lectures as one of the best specimens of its class.

**Cryptogamia.** This term was introduced by Linnaeus as the twenty-fourth and last class of his system of classification, and broadly with its present contents. The name, however (Gr. *kryptos*, 'concealed,' and *gamos*, 'marriage'), in opposition to flowering plants (Phanerogamia, q.v.), records its donor's well-founded expectation that sexual reproduction would one day be discovered. Jussieu proposed to distinguish them as *Acotyledones* from monocotyledons and dicotyledons; but the term has necessarily lapsed for many reasons. De Candolle distinguished them into two great groups, *Cellulares* and *Vasculares*; while Endlicher's separation of the vegetable kingdom into Thallophytes and Cormophytes still further recognised their vast morphological range. Armed with the microscope more recent investigators have determined the life-history and mode of reproduction of all the leading types, so not only amply confirming the hypothesis of Linnaeus, or even still further increasing their morphological importance as compared with Phanerogams, but entirely revolutionising our interpretation of the flowering plants themselves, since leading us to view them as more profoundly cryptogamic than the cryptogams. The separate groups of cryptogamic plants are outlined in the articles ALGÆ, SEAWEEDS, BACTERIA, FUNGI, LICHENS, MOSSES, LIVERWORTS, FERNS, WATER-FERNS, HORSE-TAILS, LYCOPODIACEÆ, SELAGINELLA; while their relation to higher plants is explained under PHANEROGAMIA, FLOWER, GYMNOSPERMS.

**Cryptography**, the art of secret writing, also called *Writing in Cipher*, *Hieroglyphic Writing*, *Secret Writing*, *Steganography*, *Polygraphy*, has been in use from an early date in correspondence between diplomatists and others engaged in important affairs requiring secrecy. Every government used to employ its staff of decipherers, who availed themselves of extraordinary means for interpreting despatches which (fairly or unfairly) came into their possession. The cipherers and the decipherers waged a constant struggle to outwit each other; the one by constructing new difficulties; the other by conquering the difficulties as soon as constructed. How often we hear of a courier being murdered and his despatches carried off! And without the

key to decipher letters so written, to what purpose would they be intercepted by such a deed? In these modern times, however, there has been so great an improvement in the morals of governments that the custom of killing foreign-office messengers for the sake of their despatch-bags is entirely obsolete in diplomacy, and statesmen have ceased to pillage post-offices or rifle portmanteaus for cryptographic messages.

Most of the odd knacks, contrivances, decoys, blinds, now employed by cryptographers were to some extent known to and employed by the ancients. Substituting points for vowels; arranging threads, knots, or ink-spots at determinate distances; substituting one letter for another; inventing new arbitrary characters for whole words or even sentences—now made use of extensively in telegraph codes; abbreviating words in their prefixes and affixes; writing a long sentence of nonsense, with a clue to find the words which gave the proper sense—all were brought into requisition. Perhaps the most amusing of all cryptographs was the one mentioned by Herodotus. Histæus, a Greek at the Persian court, being desirous of sending a secret message to Aristagoras at Miletus, selected a slave who was afflicted with bad eyes, and shaved his head, pretending that it was necessary for his recovery. In performing this, Histæus imprinted his secret intention in legible characters on the man's head, and kept him in close confinement till his hair grew again, when he sent him to Aristagoras for a perfect cure. Aristagoras repeated the shaving, read the writing underneath, and thus obtained the desired information by means of the unconscious messenger.

One of the simplest methods of cryptography is to use instead of each letter of the alphabet a certain other letter at a regular interval in advance. Such was a mode of secret writing adopted by Julius Cæsar. As a variety of this plan, the alphabet is used invertedly, *z* for *a*, *y* for *b*, *x* for *c*, and so on; or, while the first seven letters are represented by the second seven, the next six may be represented by the last six. And many other variations may be adopted. But the decipherment of such messages is naturally not difficult, and with a little consideration of the peculiarities of the English language, all the ups and downs of many an interesting love story related in cipher in the columns of the *Times* can be followed from start to finish with comparative ease. It is known that *e* is the most frequent letter; that *the* is the commonest word; that *ea* and *ou* are the two-vowel groups which most frequently occur; that the consonants most common at the ends of words are *r*, *s*, and *t*, &c. We also know that a word of a single letter must be either the pronoun *I*, or the vowel *a* or *O*; that *an*, *at*, *on*, *to*, *of*, and *in* are the most common words of two letters; that *the* and *and* are the most frequent words in three letters; that the most usual doubled letters are *ee*, *oo*, *ll*, *ss*, *ff*; that double vowels are mostly followed by *l*, *m*, *n*, *r*; that the letter *a* begins three two-letter words in very extensive use—*an*, *as*, *at*; that the letter *o* begins or ends eight two-letter words in very common use—*do*, *go*, *no*, *so*, *to*, *of*, *on*, *or*; that more words in a sentence of average English begin with *t* than with any other letter; that in about three-fourths of all the words in a sentence, either the first or the second letter is a vowel; that among consonants, *d* and *h* are most largely used, after which come *n*, *s*, *r*, *t*; that the letter *q* is always followed by *u*; that no English word of two letters or more ends with *i*. All these considerations will guide us to the solution of any simple cipher, enabling a skilful decipherer to read almost any ordinary piece of cryptographic writing in a very short time.

In British history, cryptography has at no time been in greater requisition than during the Civil War. Charles I.'s celebrated letter to the Earl of Glamorgan (afterwards Marquis of Worcester), in which he made some compromising concessions to the Catholics of Ireland, was composed in an alphabet (sometimes supposed to be Charles's own, but more probably Worcester's invention) of twenty-four short strokes variously situated upon a line. Other letters from the hand of the same monarch are to appearance a mere series of numbers of two or three figures divided by semicolons. In such cases it was necessary that the two parties engaging in the correspondence should have previously concerted what words each number was to represent.

In the reign of William III. the Jacobites invented many curious ciphers to enable them to communicate with their exiled king. All the Jacobite clubs had distinct methods of their own—their great aim being to write in such a manner that the very ciphers themselves should pass through their enemies' hands without suspicion. This they accomplished by means of sympathetic inks. A favourite Jacobite cipher was the use of parables, conveying, by means of ordinary language, a double meaning, which only the person acquainted with the writer's views would think of. The use of cryptography for purposes of state in England ended, it may be said, with the Peace of 1815. During the Peninsular war the government attached a cryptographer to the office of the Minister for Foreign Affairs to read and write the ciphers received and despatched. It is said that on more than one occasion the minister was unable to comprehend his own cipher.

The earliest elaborate treatise on writing in cipher is the *Steganographia* (Frankf. 1606) of the abbot John Trithemius, a MS. copy of which was bought for a thousand crowns at Antwerp by Dr Dee in 1563. Lord Bacon, who esteemed cryptography one of the most useful arts of his time, framed what he believed a not easily penetrable cipher—in which he employed only *a* and *b*, arranging each of these letters in groups of five, in such collocations as to represent all the twenty-four letters. Thus *aabab, ababa, babba* conveyed the word *fly*. In his *De Augmentis* he styled this an *omnia per omnia* cipher, believing that in this case preconcertment would be necessary; but in reality any clever modern decipherer could have read any letter composed in such a manner if it were of any length.

Mr Donnelly, in his work *The Great Cryptogram*, endeavoured in 1887 to prove that Bacon inserted a cipher in the Shakespearian plays—which he claimed was the work of the great philosopher—but the cipher was of so elaborate a kind that nobody but Mr Donnelly was able to follow its intricacies. The unfortunate Earl of Argyll used a mode of secret writing which consisted in setting down the words at certain intervals, which he afterwards filled up with other words, making of the whole something intelligible, but of no use to any one else reading the message. The Marquis of Worcester invented a cipher composed of dots and lines variously ordered within a geometrical figure; while Dr Blair made one of three dots, placed over, under, or on the line, by which he could represent no fewer than eighty-one letters, figures, or words. The Doctor, in his able article in *Rees's Cyclopædia*, declares this cipher to be as nearly as possible undecipherable by strangers; but two years afterwards, Mr Gage, of Norwich, published a pamphlet on purpose to solve Dr Blair's riddle. As he devoted fourteen closely printed octavo pages to the explanation, any description of the cipher is beyond the limits of this article. Mr Thicknesse, a well-known expert of the 18th century, also devised a plan of conveying information in the

disguise of music, the notes, rests, expression-marks, &c., standing for letters.

All the methods, however, of cryptography may thus be summarised: (1) By invisible ink; (2) by superfluous words; (3) by misplaced words; (4) by vertical and diagonal reading; (5) by artificial word-grouping; (6) by stencil-plates cut out so as to show certain words beneath; (7) by using two letters (Lord Bacon's cipher); (8) by transposing the letters; (9) by substitution of letters; (10) by counterpart tabulations; (11) by mixed symbols; (12) by a printed key and code-book, used chiefly in telegrams; (13) by the employment of numerals.

See books by Porta (1563), Blaise de Vigenere (1587), Thicknesse (1772), Klüber (1809), Romani (1875), Fleissner (1881), Katscher (1889), André Langie (trans. 1922). Telegraphic codes are a kind of cipher.

**Cryptomeria**, or JAPANESE CEDAR. This lofty and beautiful hardy coniferous tree (*C. japonica*) is widely distributed in mountain districts of Japan and China, as well as cultivated in many varieties. It was introduced by Robert Fortune in 1842, and has since passed into cultivation. Although originally confused with the cypresses, it is nearly allied to *Sequoia* and *Taxodium*. See CONIFERÆ.

**Cryptoprocta**, a fierce carnivorous animal of Madagascar, forming a genus and species by itself. Semi-plantigrade, and with beautiful fur, it resembles a large polecat, three feet long, and attacks the largest animals with great ferocity.

**Crystalline Rocks**, a name given to all rocks having a crystalline structure. The crystalline texture may either be original or superinduced. Thus some crystalline rocks, such as certain calcareous masses, owe their origin to chemical precipitation from water, while others again, such as lavas, have consolidated from a state of igneous fusion. There is another large class of crystalline rocks, the crystalline granules of which present a remarkable foliated character—that is, they are arranged in more or less parallel layers (see SCHISTS). This peculiar schistose structure appears to have been superinduced—the original rocks having been either fragmental or crystalline or both—and the result of great heat and pressure. Such highly altered rocks occur in the neighbourhood of masses of granite, and cover wide regions, where there is abundant evidence to show that the strata have been subjected to enormous compression, crushing, and crumpling—having been folded and fractured and pushed violently over each other for distances of sometimes 15 miles and more. It is therefore believed that pressure and the heat engendered by great earth-movements, and the intrusion of plutonic igneous matter, are among the most potent agencies in the production of schistose structure.

**Crystallites**, minute non-polarising bodies (the result of incipient crystallisation) occurring in the vitreous portions of Igneous Rocks (q.v.).

**Crystal-gazing**. See CRYSTALLOMANCY

**Crystallography** (from the Greek *krustallos*, 'ice,' an idea among the ancients being that rock-crystal, which may be taken as a type of crystalline minerals, resulted from the subjection of water to intense cold). Minerals, salts, and chemical substances generally (examples, rock-crystal, fluor-spar, alum, and sugar) exist in the crystalline state; and from an examination of all crystals, whether occurring naturally or obtained artificially, certain laws have been discovered, and phenomena observed, and these laws and phenomena constitute the science of crystallography. The following are the more important laws and principles of the science:

(1) *Law of Constancy of Angles*.—Crystals of the

same substance may differ much in general appearance, but when the angles between their faces are measured these angles are found constant. Thus the crystals A and B (fig. 1), when cut through in

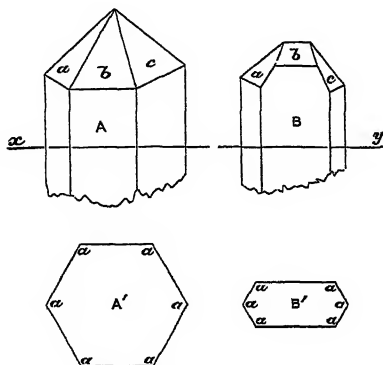

Fig. 1.

Drawings of two crystals differing much in appearance, but with angles at  $\alpha$  shown to be constant when similar sections are made.

the direction  $xy$  at right angles to the prism, give the sections shown at A', B'; and in each section the angles  $\alpha$  will be found the same—viz.  $120^\circ$ ; or again, if the angles between the faces  $ab$ ,  $bc$ , or  $ac$ , be measured, they will be found identical in both crystals.

(2) *Law of Symmetry*.—Suppose we cut a crystal in two, and then place the two parts with their cut surfaces on a mirror. The mirror will reflect each part, and may or may not produce the appearance of the original crystal. If the mirror will produce the appearance of the original crystal, we have severed the crystal in a plane of symmetry. Thus with a cube, if we cut it in either of the planes

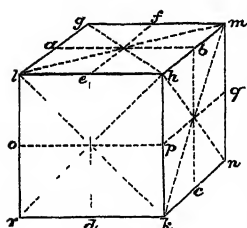

Fig. 2.

Each of the planes represented by dotted lines is a plane of symmetry.

while with other forms varying numbers of planes of symmetry may be found, until with a sphere there are an infinite number of planes of symmetry, for it is obvious that if a sphere be cut anywhere by a plane passing through its centre, and the half thus obtained be laid upon a mirror, the appearance of a complete sphere will be produced. Now on examining all (holohedral) crystals, it is found that they fall into the following six categories or systems: (1) *Anorthic System*.—No plane of symmetry—examples, copper sulphate and anorthite. (2) *Oblique System*.—One plane of symmetry—gypsum and washing-soda. (3) *Prismatic System*.—Three planes of symmetry at right angles to each other—barytes, saltpetre, and native sulphur. (4) *Rhombohedral System*.—Three planes of symmetry at  $120^\circ$  to each other—calcite, quartz, and ice. (5) *Pyramidal System*.—Five planes of symmetry—cassiterite, zircon, and idocrase. (6)

*Cubic System*.—Nine planes of symmetry—fluor-spar, galena, and alum.

(3) *Law of Rationality of Indices*.—The various planes of crystals, as explained below, are indicated in the Millerian system by three numbers, which together form the symbol of the plane. Thus we have planes represented by 1 2 3, by 1 1 1, by 1 1 0, &c. Now the law of rationality asserts that the symbol of a plane must be represented by numbers which are rational—i.e. numbers which can be expressed exactly, not those like  $\sqrt{2}$ ,  $\sqrt{4}$ , &c., which can only be obtained approximately. Thus by the law of rationality, no plane of a crystal can have such a symbol as  $1\sqrt{3}5$ ,  $1\sqrt{2}0$ , &c.

*Crystallographic Notation*.—Several methods of representing planes of crystals by symbols are in use. Two of these only need be mentioned—viz. Miller's notation and Naumann's notation. In both systems the planes are referred to three axes corresponding in direction to three edges of the crystal.

Let  $abc$  (fig. 3) represent parts or parameters cut off from three axes  $xyz$ , then in Miller's

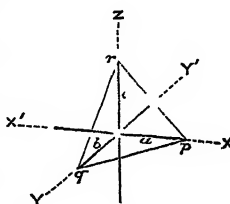

Fig. 3.

The plane 1 1 1 in Miller's notation.

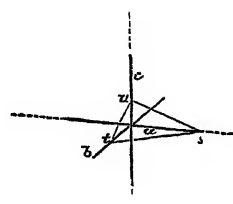

Fig. 4.

The plane 1 2 3 in Miller's notation.

system the plane 1 1 1 represents a plane which cuts the  $x$  axis at one-oneth of  $a$ , the  $y$  axis at one-oneth of  $b$ , and the  $z$  axis at one-oneth of  $c$ . Such a plane is indicated by  $pqr$ . The plane 1 2 3 means a plane which cuts the  $x$  axis at one-oneth of  $a$ , the  $y$  axis at one-half of  $b$ , and the  $z$  axis at one-third of  $c$ . Such a plane is represented by  $stu$ , fig. 4. The plane 1 1 0 means a plane which cuts the  $x$  axis at one-oneth of  $a$ , the  $y$  axis at one-oneth of  $b$ , and the  $z$  axis at one-nought of  $c$ —i.e. does not cut  $c$  at all, or is parallel to it. Such a plane is represented by  $uvwx$  in fig. 5.

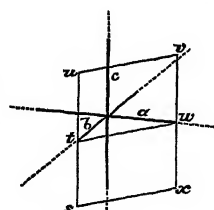

Fig. 5.

The plane 1 1 0 in Miller's notation.

In Naumann's system some form is selected as the fundamental pyramid of the crystal, and this pyramid, which corresponds to Miller's form, 1 1 1, is represented by the letter P in all systems but the cubic (in this system it is called O) and the rhombohedral (in this system it is called R). Thus the planes marked P (fig. 6) form the fundamental pyramid, the planes  $\frac{1}{2}P$  are those of a pyramid one-half the height, while the basal plane is represented by  $oP$  or a pyramid

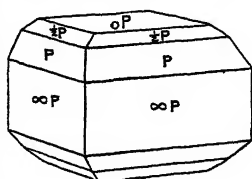

Fig. 6.

A crystal with the faces marked in Naumann's notation.

of no height, while the planes  $\infty P$  represent a pyramid of infinite height.

**Drawing and Mapping of Crystals.**—Various modes of representing crystals have been adopted. Perspective drawings are made by projecting the axes according to the rules of Projection (q.v.), then the various planes are indicated, and from these their intersections are known, and these intersections form the drawing of the crystal. Fig. 7 represents one octant of the form 2 1 1

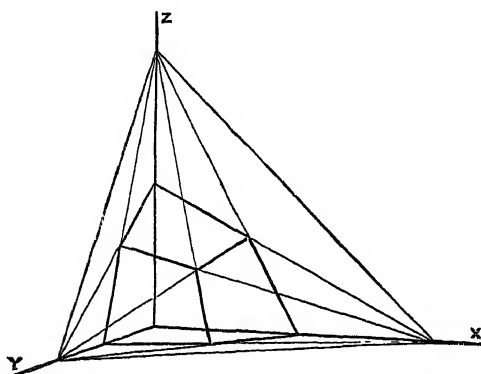

Fig. 7.  
Mode of drawing a crystal from projection of axes.

drawn by this method. Some writers represent crystal forms by orthographic projections—that is, represent them in plan and front elevation. Of all methods, however, of representing crystals from measurements made with the goniometer, the most elegant and convenient is that of spherical projections. Two kinds of spherical projection are in use—viz. the *gnomic* and the *stereographic*. Imagine a glass sphere placed within a crystal, as in fig. 8, and suppose the faces of the

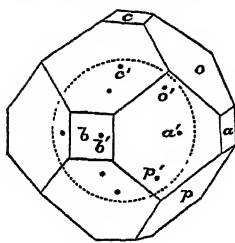

Fig. 8.  
Sphere within a crystal.  
When planes are moved they touch the sphere where dots are marked.

crystal to move parallel to their original positions until they touch the sphere, and where the faces touch let dots be marked on the sphere. Thus the face  $a$  will produce the dot  $a'$ , the face  $o$  the dot  $o'$ , and so on. When the sphere is thus marked with dots corresponding to the several faces, the next thing is to make a map of the dots in their proper position. If the map is to be made on the gnomonic projection, the sphere is supposed to be placed on the paper on which the map is to be made, and the eye is then placed at the centre of the sphere. The various dots when projected on to the paper as seen by the eye placed at the centre of the sphere produce the map. If the map is to be made on the stereographic projection, suppose a piece of glass to pass through the centre of the sphere as in fig. 9, and let the eye be placed touching the sphere at  $E$ , then the dots as they appear on the glass to the eye at  $E$  form the map. Such a map of the crystal of fig. 8 is given in fig. 10. In the stereographic projection all great circles on a sphere are represented on the map by either straight lines or arcs of circles, whereas in the gnomonic projection they are represented by straight lines. The map (fig. 10) shows not only the position of the dots or poles, but also great circles passing through

the sphere. These great circles correspond to the planes of symmetry of the cube (fig. 2) and other forms of the cubic system. These stereographic maps, as will be seen by reference to treatises on

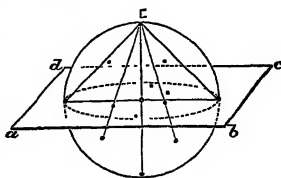

Fig. 9.  
The eye placed at  $E$  sees the dots on lower part of sphere projected on the plane  $a b c d$ .

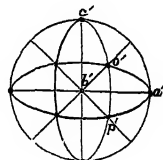

Fig. 10.  
Stereographic map of the crystal of fig. 8 as obtained by method in fig. 9

the subject, convey a good deal of information respecting the crystals they portray.

Planes of crystals form a *zone* when the intersections of the planes (i.e. the edges) are parallel to each other. Thus, in fig. 6 the faces  $oP$ ,  $\frac{1}{2}P$ ,  $P$ , and  $\infty P$  form a zone. Now in Miller's notation these forms have the indices 0 0 1, 1 1 2, 1 1 1, 1 1 0, and it will be noticed that all these symbols have a common ratio—thus, the first and second index are equal to each other. It may be shown that this is universally true; hence, knowing the indices of a plane, we can say whether it is on a particular zone, or knowing that a plane lies in two zones, we can determine its indices. Thus, the planes 1 2 3, 1 2 4, 1 2 5, &c., are all in one zone, as the symbols have the common ratio 1 : 2, and the plane 3 4 5 cannot be on this zone, because its symbol does not contain the ratio 1 : 2.

**Holohedrism and Hemihedrism.**—Crystals which have all faces present as required by the law of symmetry are termed holohedral. Where, as is often the case, only one-half of these faces are present, the crystal is said to be hemihedral; while if only one-fourth of the full number of faces are present, the crystal is said to be tetartohedral.

**Physical Crystallography.**—The physical properties of crystals have some interesting relations to the symmetry and form of the crystal, and these properties are included generally with crystallography. Thus, if in the regular system a face is striated or has any peculiarity, this striation or peculiarity will be found on each face which is present by the law of symmetry. Again, most crystals cleave (i.e. break easily) in certain directions, and the cleavage planes follow the law of symmetry. Again, when examined by polarised light, other properties of crystals in relation to symmetry are brought out. Thus, crystals of the regular system (except in a few certain cases) do not doubly refract light, no matter in what direction the light is incident. With crystals of the rhombohedral system and the pyramidal system light is not doubly refracted when it falls parallel to the vertical axis, but in other directions it is doubly refracted; while in the remaining systems two directions can be found in which the crystals of these systems do not doubly refract light, though they do so in all other directions. Again, heat is conducted differently in different systems of crystals. Suppose crystals turned in a lathe into spheres, and that the centre is made suddenly hot, then in the regular system the heat spreads equally, and after a time the surface of the sphere is uniformly raised in temperature; with other systems the effect is different; with the pyramidal and rhombohedral systems a similar experiment would result in the surface of the sphere being heated uniformly over belts corresponding to an equator and parallels of latitude, but the tempera-

ture of the different belts would be different, thus showing that heat is propagated in two directions at right angles to each other with different velocities. With other systems more complex results would be obtained owing to heat being propagated in three directions with different velocities.

When soluble crystals are placed in a solvent the faces are eaten out differently, producing figures termed by German writers 'aetzfiguren'. These figures will often indicate the symmetry of the crystal, and have been useful in such determination. As physical properties generally are related to elasticity, Groth states that the best way to define a crystal is that it is a solid body, the elasticity of which is the same in all parallel directions, but on the contrary is different in different directions.

The discovery by Laue in 1912 that crystals can act as diffraction space-gratings for X-rays has greatly extended the methods of examining crystal structure. In the original experiment a fine pencil of X-rays passes through a crystal, and subsequently falls upon a photographic plate. The impression which it makes upon the plate is surrounded by a large number of spots arranged symmetrically. These are actually a diffraction pattern; and the success of the experiment shows that it must be possible to determine the arrangement of the atoms within a crystal by the study of the pattern. W. L. Bragg (*Proc. Cam. Phil. Soc.* xvii. Pt. I. p. 43) showed how this was to be done; and his rendering of the Laue theory opened the way to a series of researches which is forming a new crystallography. It is now possible to determine the exact arrangement of the atoms within the crystal; the outward form of the crystal is no longer the chief guide to crystalline structure.

The fundamental proposition of the new analysis is concerned with the reflection of a homogeneous wave-train by a set of parallel and regularly spaced planes, each of which by itself reflects only a very small fraction of the incident train. In Fig. 11 the

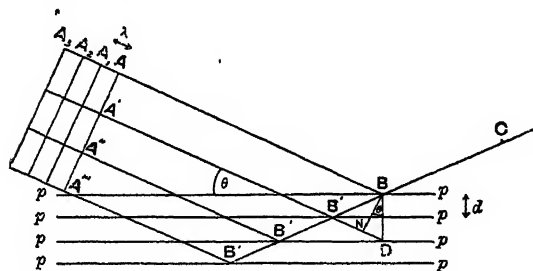

Fig. 11.

train  $A_1A_2A_3A_4\dots$  meets the planes  $p, p, p\dots$  at an angle  $\theta$ . The planes are parallel to each other and are spaced regularly at a distance  $d$ . A number of small reflections occurring at  $B, B', B'', \dots$  group themselves together into a single compound reflection along  $BC$ . All these will be in the same phase if  $n\lambda = 2d\sin\theta$ , where  $\lambda$  is the wave-length of the train and  $n$  is any whole number. (For  $A'B' + B'B - AB = A'B' + B'D - A'N = DN = 2d\sin\theta$ .) If this relation is satisfied there is a reflection; if not there is none, because the various small reflections mutually destroy each other. Rayleigh gave the theory of this peculiar effect in an explanation of the colours of crystals of chlorate of potash. These crystals contain numbers of twinning planes, parallel to each other and regularly spaced. White light incident at any angle is not reflected in its entirety; a portion which has the proper wave-length is selected, and the rest passes on.

The parallel effect in the case of a crystal occurs in the following way. The atoms of a crystal may be supposed to be arranged in sets of parallel planes; there are an infinite number of such possible arrangements. Any set can constitute a reflecting set of planes. When X-rays of wave-length  $\lambda$  meet a set at an angle  $\theta$ , reflection occurs when and only when the above condition is satisfied. In practice the number of sets of planes which can reflect X-rays of ordinary quality is limited; a small number only are sufficiently widely spaced.

If the same set of homogeneous X-rays is always used for the purpose of the experiment, and the angles of reflection in different sets of planes are found, we have a means of comparing the spacings of the various sets. In this way we may arrive at the disposition of the separate atoms. Further help is given by examination of the relative intensities of the different orders of reflection, that is, for the several cases where the whole number in the formula may be 1, 2, 3, &c. Examples will be given presently.

The instrument employed may be called an X-ray spectrometer. A fine pencil of X-rays issues from a vertical slit in a box containing the X-ray bulb, and falls upon the vertical face of a crystal mounted on a revolving table. If the angle of incidence is such that there is a reflection, the reflected pencil passes into a tube containing a heavy gas, such as sulphur dioxide or methyl bromide, which it ionises. The ionisation current is driven by the usual methods into an electroscope, and its intensity is measured. If, as is usually the case, the rays from the bulb contain a certain amount of X-radiation of a general character, on which strong homogeneous rays characteristic of the metal emitting the X-rays are superimposed, the fact is revealed by examining the reflection at all angles; and the result may be described as a line spectrum overlying a general or continuous spectrum.

An X-ray tube in which the anticathode is made of rhodium gives a spectrum containing four lines, 0.534, 0.545, 0.614, and 0.619 Ångström Units ( $10^{-8}$  cm.). When greater wave-lengths are required the anticathode is commonly made of some substance of smaller atomic weight, such as copper.

Crystals in the form of minutely divided powder are examined by an alternative method devised independently by Debye and by Hullah.

We may now take one or two examples of crystal measurement. The (100) planes of a copper crystal reflect a certain palladium ray at  $9^\circ 25'$ ; the (110) planes at  $13^\circ 20'$ , and the (111) planes at  $8^\circ 0'$ . The sines of these angles are respectively 0.1636, 0.2306, and 0.1392,

which are in the ratio  $1:1.41:0.85$ , or  $1:\sqrt{2}:\sqrt{3}/2$  nearly. From the formula given above, the spacings of the three sets of planes must also be in this proportion. But this is characteristic of an arrangement of reflecting centres in a face-centred lattice, as may be seen on examination. There are very convincing reasons for supposing that the reflecting centres are the copper atoms; and we learn that the atoms are arranged on a lattice of this form and are indeed close packed.

In similar ways it is found that the atoms of sodium in rock-salt are placed at the corners of a cube and at the centres of its faces; the chlorine atoms, at the middle points of the edges and at the cube centre, or *vice versa*. Each kind of atom is, therefore, arranged on a face-centred lattice, and one lattice can be derived from the other by a shift parallel to a cube edge. The distance from any atom to its nearest neighbours is 2.81 Ångström Units. It is interesting to observe that in such a

construction it is not possible to distinguish separate molecules within the crystal.

The structure of diamond is revealed mainly by the fact that the cleavage (100) faces give a spectrum in which the second order is absent. That is to say, reflection occurs when the whole number in the formula is 1, 3, 4, or 5, but not when it is 2. This is characteristic of a certain special spacing of the planes, in which each plane is three times as far from its neighbour on one side as on the other. It is readily inferred that the carbon atoms of a

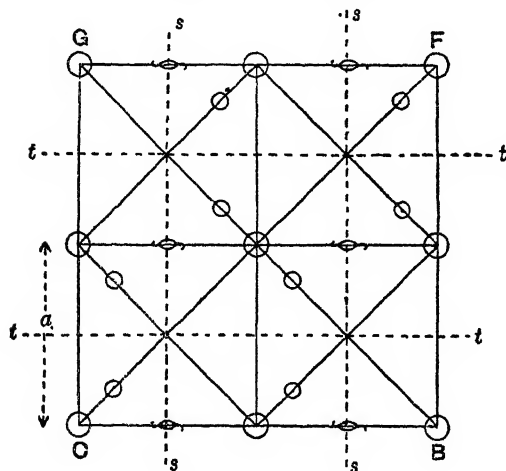

Fig. 12.

diamond are so placed that each lies at the centre of a regular tetrahedron, at the points of which lie its four nearest neighbours. The distance from any atom to any of its four neighbours is 1.51 Ångström Units.

In the case of iron pyrites, iron atoms lie at the corners and the face centres of a cube. Sulphur atoms are found in four of the eight small cubes into which the larger cube may be divided. Each sulphur atom lies on a small cube diagonal, nearly four times as far from the iron atom at one end as from the empty corner at the other. The arrangement projected upon a (100) plane is shown in fig. 12; it suggests a cause for the peculiar striations of iron pyrites, which run parallel to the pairs of sulphur atoms in each small square of the figure. The diagonals upon which sulphur atoms lie are axes of rotation symmetry; no two axes intersect.

A number of other crystals have been examined by these methods. A summary is given in *X-rays and Crystal Structure*, W. H. and W. L. Bragg (1915; rev. and enl. 1924).

**Crystalloid** is a name given by Graham to a class of substances which when in solution pass easily through membranes; as opposed to *colloids*. Metallic salts, sugar, oxalic acid, are crystalloids. See DIFFUSION, OSMOSE, PHYSICAL CHEMISTRY.

**Crystallomancy**, a mode of Divination (q.v.) which has been practised among almost all peoples. A precious stone, crystal globe, mirror, drop of ink, or other object has been employed, a Beryl (q.v.) being by some deemed most effective. In using it, the operator in some cases first muttered over it certain formulas of prayer, and then gave it into the hands of a youth or virgin—none others were pure enough to discern its revelations—who beheld in it the information required. Sometimes the wished-for knowledge was conveyed by means of

written characters on the crystal; sometimes the spirits invoked appeared in the crystal to answer the questions asked. Dr Dee (q.v.) was a great adept at crystallomancy, and two of his magic mirrors—cannel coal and smoky quartz, polished—are now in the British Museum. Lady Blessington's 'magic crystal' illuminated London 'society' in the 19th century. Crystal-gazing is still practised in the 20th century by professional charlatans who prey upon the superstitious. But experiments have also been made by scientific workers, and it seems to be established that 'scrying' (without incantations) may bring to the surface and objectify forgotten facts or other hidden contents of the mind. Some would add that certain proved experiences of crystal-gazers can only be explained by telepathy or clairvoyance. See books by J. Melville (1903), N. W. Thomas (1905), T. Besterman (1924).

**Crystal Palace.** See SYDENHAM.

**Csaba**, or BÉKÉSCSABA, a town of Hungary, 7 miles S. of Bakes, has a trade in grain, flour, wine, hemp, and cattle; pop. 47,000.

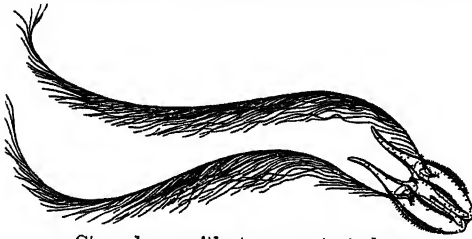

**Csárdás.** See CZARDASCH.

**Csoma de Kőrös**, ALEXANDER, a Hungarian traveller and philologist, born 4th April 1784 in the Transylvanian village of Kőrös, was educated first at the college of Nagy-Enyed, and subsequently at Göttingen, where Eichhorn the Orientalist inspired him with a passion for philology. In 1819 he studied Slavonic in Croatia with his customary ardour, and next year started on his pilgrimage to central Asia, finding his way in Asiatic dress with the most indomitable perseverance by Bagdad and Teheran to Bokhara, thence by Kabul and Lahore to Kashmir and Tibet. He soon began to devote himself to a study of the Tibetan language under the patronage of the English government. Early in 1827 he started on his third journey thither, and remained in the country for three years, completely absorbed in study, and indifferent to the extreme cold of winter and to privation of every kind. Early in 1831 he arrived at Calcutta, where he completed his Tibetan grammar and dictionary. He was appointed librarian to the Asiatic Society, but no comforts could wean him from his love for travel. In January 1836 he started on another journey to Tibet, but died of fever six days after arriving at Darjiling, 30th March 1836, a veritable martyr to science. His life was written by Dr Theodore Duka (1885), who disposed of the assertion so often made that the traveller's zeal, at least after the years of mere boyhood, was due to a devout imagination that somewhere in the heart of Asia it was possible still to discover the original home of the Magyar race.

**Csongrád**, a town of Hungary, at the confluence of the Theiss and the Kőrös, 75 miles SE. of Budapest. The inhabitants, 25,000 in number, are chiefly engaged in the rearing of cattle, fishing, making of wine and soap.

**Ctenophora** (literally, 'comb-bearers'), a subclass of Coelenterates (q.v.), representing the climax of activity in that series of animals. The Common Beroe and Pleurobrachia are good types. Venus' Girdle (*Cestum veneris*) is a well-known aberrant form, which has been elongated sideways to a yard or more in length. They are beautifully delicate, free-swimming marine organisms, generally globular in form, moving by means of comb-like plates. These are composed of numerous agglutinated cilia, and disposed along eight meridional rows. The mouth is at one pole of the sphere; two excretory or anal apertures lie at the other, which also exhibits a sense organ and a probable steering mechanism usually known as the 'otolith.' There are numerous alimentary vessels regularly disposed

in relation to the main central cavity. In most cases there are two retractile tentacles; the stinging-cells so characteristic of Cœlenterates are usually modified into 'adhesive cells.' The Ctenophores are hermaphrodite, carnivorous in diet, extremely active in habit, and often phosphorescent.

Ctenophore, with streaming tentacles.

The Ctenophora are very divergent from other Cœlenterates, e.g. in the almost complete absence of stinging-cells, in the early establishment of a mesodermic germinal layer, in usually showing two tentacles (except in Beroidæ), and in having the peculiar ciliated combs. There is a good deal of evidence in support of the view that they point the way to the Turbellarian Flat Worms (as is suggested by *Ctenoplana* and *Cœloplana*). See BEROE, CœLENTERATA.

**Ctesias**, a Greek historian of Persia, was private physician of Artaxerxes Mnemon, and accompanied him in the expedition to crush the revolt of his brother Cyrus, 401 B.C. His *Persika* was a history of Persia in twenty-three books, written in the Ionic dialect, but unhappily only a meagre fragment can be recovered in an abridgment in Photius, and in some portions preserved by Diodorus and other writers. Ctesias compiled his history from oriental sources, and it is not wonderful that his statements often contradict those of Herodotus. Of his *Indika* also only an abridgment by Photius is extant.

**Ctesibius**, a Greek who flourished under Ptolemy Philadelphus and Euergetes, at Alexandria, about 250 B.C., and was famous for his inventions in mechanics. We owe to him and his pupil Hero Alexandrinus the pump, the bent siphon, and also the discovery of the elastic force of air, and its application as a motive-power.

**Ctesiphon**, a city of Babylonia, on the eastern bank of the Tigris and opposite Seleucia, the common winter residence of the Parthian kings, and finally the capital of the Parthian kingdom. It was conquered by the Romans in 115 A.D., and destroyed by the Arabs under Omar in 637. The British defeated the Turks there 22d November 1915. Its ruins still attest its former magnificence.

**Cuba**, the most westerly and largest island of the West Indies, till 1898 the principal colony left to Spain, stretches in the form of a long narrow crescent, convex on the north side, at the entrance of the Gulf of Mexico, which it divides into two channels—the north-west, 124 miles wide, and the south-west, 97½ miles at its narrowest part. Cuba is 759 miles long from Cape Maisi on the east to Cape Antonio on the west, with a breadth varying from 27 miles to 90 miles, and an area of about 45,000 sq. m. Only about one-third of the coast-line is accessible to vessels, the remainder being beset by reefs and banks. The shores, low and flat, are liable to inundations, but there are numerous excellent havens. In the south-east are the Sierra de Maestra shooting up in the Pico de Turquino to 8400 feet, and the Sierra del Cobre (copper). The mountains, composed of granite overlaid with calcareous rocks, and containing

minerals, especially copper and iron, are clothed in almost perennial verdure, wooded to the summits. Carboniferous strata appear in the west, schistose rocks on the north coast. The limestone rocks abound in caverns, with magnificent stalactites. Mineral waters are plentiful. The climate, more temperate than in the other West Indian Islands, is salubrious in the elevated interior. No month of the year is free from rain, the greatest rainfall being in May, June, and July. Earthquakes are frequent in the east. Hurricanes, less frequent than in Jamaica, sometimes cause widespread desolation.

Among the animals are a species of tailless rat peculiar to Cuba, great abundance of birds, including the mocking-bird, a species of vulture (valuable as a scavenger), woodpecker, partridge, flamingo, albatross. Of noxious animals there are the crocodile, scorpion, and mosquitoes. The rivers and seas are well stocked with fish; and turtle abound in the shallows and sandy places of the beach.

Sugar, for which soil and climate are peculiarly favourable, has long been the chief product, and the island is now responsible for about one-quarter of the world's supply. Tobacco, though far behind, is next in importance. Other important crops are sweet potatoes, bananas, maize, rice, and many fruits; cocoa and coffee are also grown. The rearing of live-stock is extensively carried on, and bee-keeping is a thriving industry. Iron, manganese, and copper are worked; and oil and asphalt are got. The principal exports are sugar, tobacco, copper, iron ore, fruits, wood, cigars, cattle hides, honey and beeswax, molasses, cocoa, manganese, asphalt, &c.; these are mostly to the United States, with whom since 1903 a reciprocal commercial treaty has existed.

In 1887 the population was 1,631,687; in 1899 it was 1,572,797, the decrease being due to war; in 1919 2,889,004, three-fourths whites. The principal towns are Havana (q.v.), the capital, pop. 363,500; Camagüey, 98,000; Cienfuegos, 96,000; Santiago de Cuba, 70,000; Guantánamo, 69,000; Santa Clara, 63,000; Matanzas, 63,000; Sancti Spiritus, 59,000; Manzanillo, 57,000; Pinar del Río, 48,000; Trinidad, 41,000; Cárdenas, 33,000. The educational system is good, and there is a university at Havana dating from 1721. There are about 3200 miles of railway connecting the principal towns and seaports, and the road system is being greatly extended.

Cuba, spoken of as the 'Queen of the Antilles,' was discovered by Columbus in 1492, the discoverer calling it 'the most beautiful land that eyes ever beheld.' It was first settled by Spaniards at Baracoa in 1511. Havana, first settled in 1519, was reduced to ashes by the French in 1538, and again in 1554. For about a century and a half Cuba was in constant danger from French, English, Dutch, and West Indian filibusters. In 1762 the English under Lord Albemarle (q.v.) took Havana, which, however, was by the Treaty of Paris next year restored to Spain. Hitherto the whole Spanish trade with the colonies had been in the hands of a single privileged company. During the ten months' English occupation, Havana, open to free trade, showed in its port, instead of ten to twelve ships yearly as formerly, more than one thousand, and agriculture made rapid progress. In 1818 Cuba was opened to the world's trade, and soon reached unexampled prosperity. The civil war in the United States ruined its sugar industry and so benefited Cuba; but the suppression of slavery by the Spanish government (1880-86) without compensation created discontent not abated by the constitution of 1884. A serious insurrection took shape in 1895. Absolute freedom from Spanish rule was demanded, a Cuban republic was proclaimed, and soon a bloody guerilla

war was in progress. In their efforts to crush the rebellion the Spanish government sent to Cuba upwards of 200,000 soldiers, of whom a very large proportion died in hospital. The savage and destructive character of the war, and the cruelties believed to have been shown by the Spaniards even towards non-combatants, provoked very pronounced sympathy with the insurgents on the part of the United States, and American intervention was repeatedly threatened. The destruction of an American warship by an explosion in Havana harbour embittered American feeling, and in April 1898, the United States and Spain were at war. The harbour of Havana was blockaded, but the centre of military operations was Santiago; and a brief war was ended by the total destruction of the Spanish fleet in August. On the conclusion of peace in 1899 Cuba became practically a dependency of the United States—in the first instance a military protectorate—and as such was occupied for three years. The administration was reorganised; roads, railways, docks, and harbours were made or improved, and sanitary regulations enforced. Taxes, customs, and education were put on an improved basis, and many other reforms made. A constitution being drafted and adopted, on 20th May 1902 the United States officials withdrew from the island, their government having previously propounded a series of conditions to which the agreement of the Cubans was obtained, and the republic of Cuba was formally established, Tomás Estrada Palma being the first president. An insurrection in 1906 led to a renewed occupation by United States troops until 1909, and a negro rising in 1912 compelled the despatch of an American squadron. During the Great War, Cuba entered on the side of the Allies, 7th April 1917.

See books on Cuba by Gallenga (1873), Hazard (1871) and Ballou (1885), Larrinaga, Piron (Paris), Davies (1897), Davey (1898), Porter (1899), Wright (1917); and works cited at WEST INDIES.

**Cubango.** See NGAMI.

**Cube**, a solid bounded by six equal square faces, opposite pairs of which are parallel; the three edges meeting at any point being at right angles to one another. This form frequently occurs in nature, especially among crystals (see CRYSTALLOGRAPHY). In arithmetic, the cube of a number is the product of its multiplication twice by itself; if the edge of a cube be a line of 4 inches, its solid content is 64 cubic inches. The cube root of a number is that number which, multiplied twice by itself, produces the first number. See INVOLUTION, ROOT, DOUBLING THE CUBE.

**Cubebs**, or CUBEBS PEPPER, the dried berries of *Piper Cubeba*, a climbing shrub, a native of Sumatra, Java, and southern Borneo. The fruits of other species of *Piper* are sometimes substituted for the true cubeb. Known to the Arabs in the middle ages, cubebs fell gradually into disuse, till at the beginning of the 19th century all reference to it was omitted in medical books, and its importation ceased. It has come again into use. As a stomachic and carminative it has some value; in piles and in sore throats it is beneficial; and in gonorrhoea its application is important. It is often contained in asthma-cigarettes. In the East it is used as a condiment.

Cubebs contains a volatile oil, a crystalline substance called *cubebin*, and resinous bodies, one of which is *cubebic acid*. The cubebin is inactive, while the volatile oil is not believed to have the full virtue of the cubebs. It enters, however, into the composition of a well-known voice lozenge, to which it imparts highly stimulating properties. The diuretic properties are held by some to be entirely due to the resinous bodies, but on this

point there is a difference of opinion. The dose of powdered cubebs is from one to three drachms, that of the volatile oil ten drops, and of the oleo-resin five to thirty drops.

**Cubic Equations.** A cubic equation in a given quantity is an equation in which the highest exponent of that quantity in any term is 3. Every such equation can be reduced to the form  $x^3 + px + q = 0$ , where  $x$  is the variable and  $p$  and  $q$  are constants. Every equation of this form has three roots, all of which may be real, or one may be real and two imaginary. An equation containing any number of variables in which the greatest sum of the exponents of the variables in any term is 3 is called a cubic equation. Thus  $x^2y + 5y^3 + 6 = 0$  and  $xyz + z^2 = 0$  are cubic equations in  $x$ ,  $y$ , and  $z$ ,  $y$ , and  $z$  respectively. See EQUATIONS.

**Cubism.** See PAINTING.

**Cubit** (Lat. *cubitus*, 'forearm'), a Roman measure of length, supposed to equal the length of the forearm from the elbow to the tip of the middle finger. It was  $1\frac{1}{2}$  Roman feet ( $17\frac{1}{2}$  English inches). The English cubit is  $1\frac{1}{2}$  feet. The cubit of the Bible is generally estimated at 22 inches, though that of Egypt, Babylon, and Asia Minor was slightly over  $20\frac{1}{2}$  inches.

**Cubitt**, SIR WILLIAM (1785–1861), engineer, born at Dillham, in Norfolk, was a miller, cabinet-maker, and millwright until 1812, when he became chief engineer and later a partner with Messrs Ransome at Ipswich. In 1823 he joined the Institution of Civil Engineers, and was afterwards engaged in many public undertakings. The improvement of the Severn and of Boulogne port, the Bute docks at Cardiff, the Berlin water-works, and South-eastern Railway are among his works. He also invented the treadmill; and for his services in connection with the erection of the Great Exhibition buildings he was knighted in 1851.

**Cucking-stool.** See DUCKING-STOOL.

**Cuckoo** (*Cuculus*), a well-known genus of birds in the order Cuculiformes, or, according to others, Picariæ, and type of a large family (Cuculidæ). The common cuckoo (*Cuculus canorus*) is a widely distributed bird, breeding in summer in the northern parts of Europe and Asia, and migrating in winter to Africa, as far as the Cape, or to India.

Cuckoo.

It is best known for the 'coo-coo' cry with which the male announces its arrival in spring, and for its habit of utilising for its own family the nests and the brooding of other birds. The cuckoo is slightly over a foot in length; the bill is as long as the head, slender and slightly curved; the wings are long and pointed; the tail is also long and rounded; the upper part of the shank is feathered.

The upper surface is ashen gray, the belly and legs are whitish with undulating transverse brown lines, the tail is spotted with white above, and the root of the bill and the feet are yellow. The young birds are brownish above with a white spot on the nape. A reddish variety occasionally occurs. The bird arrives in north Europe in April or May, and leaves again in August or September. Its cheerful call ceases to be heard about the middle of June. Predominantly an arboreal bird, it is rare in treeless districts. Each cuckoo seems jealously to 'preserve' a certain territory for itself. Like the other species of *Cuculus*, it is a shy, restless, unsocial bird. It is extremely valuable on account of its insatiable appetite for caterpillars. The hairy forms are especially delighted in, and the indigestible hairs form a felt-like coating in the stomach. The female places her eggs singly (sometimes to the number of eight), each in the nest of some suitable bird, choosing such as feed their own young on insects—in order of preference, hedge-sparrow, water-wagtail, titlark, yellow-hammer, green linnet, and whin-chat. The young cuckoo, unconsciously reared by its foster-parents, manages to secure the bulk of the food-supply, and in the struggle for existence completely monopolises the nest, ousting the rightful brood. Stories of the young bird devouring its foster-parent are mythical. In some cases the adult cuckoo destroys the foster-parent's eggs. The males greatly outnumber the females. The latter has a low 'water-bubbling' or whistling cry. The males are said to be very passionate in their love-making, but there is no regular pairing or continued attachment. The musical interval between the cuckoo's two notes is not uniform, and varies from a minor to a major third (the latter being that adopted in Beethoven's reproduction). See *Nature*, vol. xxxvi. p. 344.

There are over forty genera in the cuckoo family—e.g. *Coccytes*, *Eudynamis*, *Seythrops*, and *Coccyzus*. The Great Spotted Cuckoo, *Coccytes glandarius*, which puts its eggs in the nests of magpies and crows, has occurred a few times in Britain. The Indian Koël (*Eudynamis honorata*), supposed to foretell rain, also utilises the nests of crows. The Black-billed Cuckoo of America (*Coccyzus erythrophthalmus*) builds a slight nest, and is somewhat irregular in its laying and in its parental care. The Coucals (*Centropus*), the Road-runners or Ground Cuckoos (*Geococcyx* and *Carpococcyx*), the Anis (*Crotophaga*), are other members of the family. The so-called parasitic habit of the cuckoo is in many respects puzzling. (1) It is by no means restricted to the European cuckoo, but it is not exhibited by all the members of the family. Thus it does not occur in the American cuckoo. On the other hand, it is exhibited in diverse degrees by species of the far-separated genus *Molobrus* or cowbirds, allied to the weaver-birds. It is also of interest to notice that there are scattered instances of many different species of birds laying their eggs in the nests of unrelated types. (2) The usual procedure seems to be that the mother-cuckoo lays her egg on the ground, then takes it in her bill, and puts it as quickly as possible in a suitable nest. According to Baldamus, Chance, and some others, she may lay her egg in an open nest. Each hen is believed to produce eight or more eggs, and the laying occurs at intervals of two or three days, or even more. The egg is small in proportion to the size of the bird, and is very variable in its colouring. There is considerable evidence that the eggs of any individual cuckoo are all of the same coloration. Very remarkable is the frequently close resemblance between the coloration of the cuckoo's egg and that of the foster-parent, but it has not been proved that this is of actual advantage; and it must be noticed that the dis-

similarity is as conspicuous in many cases as the resemblance in others. It is possible that the cuckoo does to some extent, when she is not hurried, select a nest with eggs like the type which she lays. For fresh observations on the cuckoo's habits, especially as regards laying an egg in a nest, reference should be made to Mr Edgar Chance's admirable book, *The Cuckoo's Secret* (1922). (3) The relatively small egg of the cuckoo, incubated by the foster-parent, hatches in eleven or twelve days. As the incubation-periods of the foster-parents are usually about thirteen to sixteen days, the egg of the cuckoo hatches before or about the same time as the others, if deposited early in their incubation. This is an advantage, for the newly-hatched cuckoo has only to deal with eggs and very small nestlings. These it ejects from the nest by clambering backwards up the side, pushing before it an egg or nestling which rests in the hollow of its broad back. This depression disappears in about ten to fourteen days, when the ejecting instinct also dies away. It is noteworthy that the young bird will throw itself backwards with some force when it is touched unexpectedly. The attempts at eviction may begin when the young cuckoo is only thirty hours old, and quite blind and naked. The normal result is that the young bird is successful in making room for itself. It has been known to deal with a weaker or younger member of its own kin (if two cuckoo-eggs happen to have been placed in the nest) as it deals with the eggs or young of its foster-parent. In peculiar cases the ejecting reaction seems to be ineffective, and it may be that the foster-parents then remove their suffocated young ones. For about three weeks the young cuckoo remains in the nest, and is faithfully fed by the foster-parents, though it has meant the destruction of their own brood. Eventually the young cuckoo may be three times the size of its nurses. (4) Darwin suggested that the peculiar habit of the cuckoo may have arisen as an adaptation to the fact that the bird lays its eggs not daily, as is usual, but interruptedly. Jenner pointed out that the device enabled the cuckoo to have a numerous progeny during the short period of their stay in northern Europe. The parasitic habit, in other words, makes it possible for the cuckoos to leave early on their autumnal migration, and it is important to note that the adults leave a month or so before the young birds. It is not difficult to see advantages in the habit; it is the problem of its origin that is so perplexing. (5) In the American cuckoo (*Coccyzus erythrophthalmus*) there is a clue. It exhibits a tendency to lay at irregular intervals, so that there are eggs and young in the nest for a longer time than usual. The disadvantage of this is lessened by the fact that the young ones leave the nest very early (on the seventh day after birth) and show an interesting climbing stage for a couple of weeks. When disturbed in its nest-activities, the American cuckoo has been known to transfer its eggs to another nest of its own making, and it has been known to lay in other birds' nests. (6) Professor F. H. Herrick has advanced our understanding of the problem very notably by pointing out that the loss of the nesting instinct in various cuckoos and cowbirds is due to an irregularity in the rhythm of the reproductive cycle. In most birds the cyclical instincts connected with reproduction follow one another in a definite harmonious series, but, abnormally, one term in the series may be weakened or dropped out, another exaggerated or prolonged, and so on. There are many cases of individual disturbance in the chain; thus a bird may build a superfluous nest, or drop its eggs on the ground, or migrate too soon. A lack of attunement between egg-laying and nest-building is casual in many birds, it has become established.

in some cuckoos and cowbirds, and adjustments have been made to meet it. (7) Finally, perhaps, it should be noted that the non-brooding is not to be held apart from the other peculiarities of the cuckoo, such as the great preponderance of males, the polyandry, the gluttonous appetite, the solitary individualism, and the behaviour of the nestling. A peculiar habit should always be considered in its setting, along with the whole constitution and character of the organism.

The folklore of the cuckoo is almost inexhaustible in every country of Europe. It has the gift of prophecy as the herald of spring and of long life, the prelude of storms, of prosperity, and of speedy marriage to maidens. Countless superstitions, and those of the most varied character, are connected with its origin, the cause of its cry, its winter transformation into a hawk, as well as with the first hearing of its call, the hearer's occupation at the moment, and the direction from which it comes; while as many proverbs play upon the monotony of its note, its supposed stupidity, and its obvious connection with cuckoldom, from its habit of depositing its offspring with alien parents. It has only been by a strange transference of meaning that the name *cocu* or *cuckold* has been transferred from the paramour to the unsuspecting husband, unless *cuckold* means, as explained by Littré, one who has been *cuckoo-ed* or treated after the manner of the cuckoo. An early English song (13th century) is an expression of the joyousness of the cuckoo-call.

For details of Cuckoo folklore, see Mannhardt in the *Zeitschrift für Deutsche Mythologie*, vol. iii. pp. 209-298; James Hardy's 'Popular History of the Cuckoo,' in Part II. (1879) of *The Folklore Record*; and Swainson's *Folklore of British Birds* (1886).

**Cuckoo-flower.** See CRESS.

**Cuckoo-pint.** See ARUM.

**Cuckoo Spit.** See FROTH-FLY.

**Cucumber** (*Cucumis*), a genus of Cucurbitaceæ. The Common Cucumber (*C. sativus*), distinguished by heart-shaped, acuminate pentangular leaves, which are rough with hairs

Common Cucumber (*Cucumis sativus*):  
a, fruit.

approaching to bristles, and oblong fruit, is a native of the middle and south of Asia, and has been cultivated from the earliest times. Its fruit forms an important article of food in its native regions, the south of Europe, &c., and an esteemed delicacy in colder countries, where it is produced by the aid of artificial heat. Many varieties are

in cultivation, with fruit from 4 inches to 2 feet long, rough, smooth, &c. Young cucumbers are much used for pickling, and are called *gherkins*; a small fruiting variety is selected for this purpose. The cucumber is cultivated in fields even in the south of England, for the supply of the London market; but in all parts of Britain the plants required for the purpose of growing either in the open or under glass must be reared in a hotbed in spring. In the northern parts it can only be successfully cultivated in frames during summer. A large trade is now done in winter crops of cucumbers, which are grown in well-heated, specially constructed glass-houses. In many parts of the United States it will, if planted late enough to escape the frosts, grow well with almost no care. But it requires rich soil, much moisture, and heat. To this genus belong other species valued for their edible or ornamental fruit, but all that are popularly named cucumber are not properly *Cucumis*, but merely species or varieties belonging to allied genera. *Dudaim* (*C. Dudaim*) is a highly fragrant, handsome fruit, with insipid flavour and flaccid flesh, often grown in this country by gardeners under the name, *Queen Anne's Pocket Melon*, simply for its attractive appearance, the fruit being about the size of an ordinary orange, and beautifully barred with green and orange or deep orange-red. (*Dudaim* is the Hebrew name rendered *Mandrake* in Scripture.) *Connemon* is the fruit of *C. conomon*, which is grown everywhere in Japan, and preserved and sold as an article of food. *C. anguria*, a West Indian species, with fruit about the size and shape of a pullet's egg, is esteemed as an ingredient in soups, and is also eaten raw, but considered inferior in that state to the common cucumber. The Snake Cucumber (*C. flexuosus*) has fruit of great length which is eaten either pickled or raw, and has similar qualities to the common cucumber. A number of species of Cucurbitaceæ are natives of the United States, but they are all of small economic importance. For other representatives of the natural order Cucurbitaceæ (q.v.), see COLOCYNTH, ELATERIUM, MELON, &c.

**Cucumber-tree.** See OXALIDACEÆ.

**Cucumis.** See CUCUMBER, MELON.

**Cucurbitaceæ**, an important order of sym-petalous dicotyledons, of which the 650 species are mostly herbaceous climbers, inhabiting the warmer regions of the globe; only one, the Common Bryony (q.v.), reaching the south of England. The young shoots and leaves of many species are used as potherbs, and the persistent rhizomes or roots of others are sometimes esteemed on account of their store of starch. Acridity, however, is a common characteristic of the order; and Bryony, Elaterium, and especially Colocynth (q.v.) are of old medicinal repute. But the central importance of the order is due to the characteristic fruit, which is technically known as a *pepo*, but which may be regarded as a large and many-seeded berry, with its more or less succulent pulp protected by a hardened wall. The many specific and varietal forms are known as Cucumbers, Melons, Gourds, Pumpkins, Squashes, Vegetable-marrows, Bottle-gourds, &c., and are described under separate articles. The seeds of some species are medicinal, others edible, while the fibro-vascular skeleton of the fruit of an Egyptian species of *Luffa* (loofah) is a familiar adjunct of the bathroom.

**Cúcuta**, SAN JOSÉ DE, an inland town in north-east Colombia, on the Río Zulia, 35 miles S. of Puerto Villamizar by rail. It is the third commercial town of the republic, a centre of coffee and cacao cultivation. It was destroyed by earthquake in 1875, but has been well rebuilt.

Pop. 30,000.—ROSARIO DE CUCUTA, to the SE., was the seat of the first Colombian congress in 1821, and the birthplace of the patriot General Santander (1792–1840). It has large plantations of coffee and cacao. Pop. 6000.

**Cud**, the sodden bolus of hastily swallowed fodder which Ruminants (q.v.) drive from their paunch and honeycomb stomach back again into the mouth. There the cud is leisurely chewed, and the semi-fluid result passes down again into the stomach, usually into the manyplies. One bolus is driven upwards after another until the greater part of the cropped herbage has been chewed.

**Cudbear**, a dye-stuff, is Archil (q.v.) paste dried and ground. With indigo, logwood, fustic, and other colouring materials it gives rich browns. The preparation of archil, known as Fiench purple, was used for a short time in calico-printing, and produced fine and delicate purples, but it was superseded by aniline mauve. The ancient Cretan purple was probably obtained from the same source. The name cudbear is derived from that of Dr Cuthbert Gordon, under whose management the manufacture was begun in Leith about the year 1777.

**Cuddalore** (*Kūḍalūr* or *Gudulūr*), the chief town in South Arcot, Madras, on the Coromandel or east coast of Hindustan. It is situated on a backwater formed by the confluent estuaries of two rivers, 16 miles S. of Pondicherry, and 127 S. of Madras by rail. It has a large trade by land with Madras in oils, indigo, and sugar, and exports grain by sea. Though the river itself is silted up, and admits only native craft, yet there is good anchorage off-shore at the distance of a mile and a half. Cuddalore was at one time a place of great strength; and in that respect it was frequently an object of contention in the wars which, during the later half of the 18th century, so long desolated this neighbourhood. In 1753 it was taken by the French from the British, who had held it for 77 years; and was finally ceded to the British in 1785. Pop. 57,000.

**Cuddapah** (KADAPA), a town in the province, and 161 miles NW. by rail of the city, of Madras. It stands, at the height of 507 feet above the sea, near the south bank of the northern Pennar, which flows into the Bay of Bengal. Till 1868 it was a military cantonment. Pop. 18,000.—The district of Cuddapah, partly lowland and partly highland, has an area of 5900 sq. m., and a pop. of 900,000. It has been British since 1800.

**Cuddesdon**, a village of Oxfordshire, 6 miles ESE. of Oxford. Here is the palace of the bishops of Oxford, rebuilt by Bishop Fell in 1679, with a chapel added in 1846 by Bishop Wilberforce, to whom the adjoining theological college (1854) also owes its existence. The church is a fine old cruciform building.

**Cuddy** was the name first applied in East India trading ships to a cabin under the poop, where the men messed and slept. The same name was afterwards given to the only cabin in very small vessels, and sometimes to the cooking-room.

**Cudweed**, the popular name of many small inconspicuous species of composite weeds of the genera *Gnaphalium*, *Filago*, and *Antennaria*, the stems and leaves of which are more or less covered with a whitish cottony down. The heads of flowers consist, in great part, of dry involucreal scales, and may be kept for a long time without undergoing much apparent change, so that they may be reckoned among *Everlasting Flowers* (q.v.). *Antennaria dioica* (also called Cat's-foot) is very frequent in dry mountain-pastures. All the three genera are represented in Great Britain, and

also in the United States, where *Gnaphalium polycephalum* has some repute in domestic medicine.

**Cudworth**, RALPH, the chief figure in the group of 'Cambridge Platonists,' was born in 1617 at Aller, in Somersetshire, and admitted pensioner of Emmanuel College, Cambridge, in 1632. He graduated B.A. in 1635 and M.A. in 1639, and was in the same year elected fellow of his college, where he became a popular tutor. In 1645 he was appointed by parliament Master of Clare Hall, and in the same year regius professor of Hebrew. In 1650 he was presented to the college living of North Cadbury, in Somersetshire, and in 1654 was elected Master of Christ's College, an appointment the confirmation of which at the Restoration his acquiescence with the rule of the Commonwealth did not prevent. In 1662 he was presented by Archbishop Sheldon to the rectory of Ashwell, Hertfordshire; and in 1678 he was installed prebendary of Gloucester. He died at Christ's College, July 26, 1688. His daughter Damaris, who became the second wife of Sir Francis Matcham of Oates, in Essex, was a friend of Locke, and herself wrote a well-reasoned *Discourse concerning the Love of God* (1696).

Cudworth's great work, entitled *The True Intellectual System of the Universe*, was published in 1678. It is a learned, ample, and discursive work, singularly large-minded and sagacious; but its logical consistency as a consecutive argument is somewhat marred by discussions on such subjects as the true meaning of the pagan mythology, and the relation of the Platonic and Christian trinities. Its aim was to establish the reality of a supreme divine Intelligence against the materialism of Democritus and Epicurus, the 'atheism of atomicism;' to vindicate the eternal reality of moral ideas against the old nominalists and their successors; and to prove the reality of moral freedom and responsibility in man as against pantheistic naturism and stoicism. The only basis for a philosophy of religion rests on the conception of man as a free moral subject, capable of choosing good or evil. The portentous erudition of this famous treatise, and the redundant fullness of its endless digressions, with its strange Alexandrian amalgamation of fancy and speculation, have tended to obscure its real merits. Perhaps its most honourable distinction is the marvelously honest and impartial statement of the best arguments of his antagonists, which, indeed, laid him open to the charge of having fallen into the same heresy with Milton and with Clarke, and even into atheism, simply for being just to the arguments of atheistic writers. 'He has raised,' says Dryden, 'such strong objections against the being of a God and Providence that many think he has not answered them'—'the common fate,' adds Shaftesbury, 'of those who dare to appear fair authors.'

Cudworth's admirable sermon, preached before the House of Commons in 1647, shows the best features of that much-abused Latitudinarian school to which he belonged, and, says Mackintosh, 'may be compared even to Taylor (*Liberty of Prophecy*, published the same year) in charity, piety, and the most liberal toleration.' In its insistence upon the co-ordinate relativity of all knowledge, and the connection of religion with life and morality, the author lays down a sound basis for a harmony between philosophy and religion, between reason and faith. Many of Cudworth's MSS. still lie unprinted. His *Treatise concerning Eternal and Immutable Morality* was published in 1731, and is a contribution of real value to ethics. See Tulloch's *Rational Theology in England in the XVII. Century* (1872), Dr Martineau's *Types of Ethical Theory* (1885), and monographs by Lowrey (New York, 1884) and W. R. Scott (1891).

**Cuenca**, a picturesque decayed city of Spain, 85 miles ESE. of Madrid. It stands on a rocky hill-girt eminence, 2960 feet above the sea-level, at the confluence of the Jucar and Huecar—the latter spanned by the noble bridge of San Pablo (1523), 150 feet high and 350 long. Of Moorish origin, Cuenca has narrow, crooked streets, and a very interesting cathedral (1177–1669). Pop. 13,000. —Cuenca gives name to a mountainous, well-watered province, yielding excellent timber, honey, wine, and grain, with good pasture, and various minerals, including iron, coal, copper, and silver. Area, 6726 miles. Pop. 282,000.

**Cuenca**, a city of Ecuador, on the Río Paute, 190 miles SSW. of Quito, stands on a fertile tableland, 8469 feet above the sea, and enjoys a perpetual spring. It is the seat of the Azuay University. Its streets are wide, and several canals intersect the town; the principal buildings are the cathedral and high school. There is some trade in cheese and grain, and manufactures of hats, woollens, earthenware, and candied fruits. Pop. 30,000.

**Cuernavaca**, capital of the Mexican state Morelos, lies in a lovely and fruitful valley, about 40 miles S. of Mexico city. It has a church built by Cortes, an agricultural school, and refineries of sugar and brandy. Pop. 13,000. Near by is the famed *teocalli* of Xochicalco, with five terraces.

**Cuevas de Vera**, a town in the Spanish province of Almería, situated on the Almanzora. It has an old Moorish castle, and a considerable industry in connection with the silver-mines of the neighbouring Sierra Almagrera. Pop. 20,000.

**Cufic**. See KUFIC.

**Cui**, CÉSAR ANTONOVICH, a leader of the school of Russian composers, though himself Russian neither in his music nor in his birth, was born at Vilna, 18th January 1835, son of a Frenchman and a Lithuanian. He studied military engineering at St Petersburg, became a lecturer on fortifications and a lieutenant-general. His music is delicate rather than strong. It includes *William Ratcliff*, *Angelo*, *Le Flibustier*, *The Saracen*, and other operas, and many songs.

**Cui Bono?** ('for whose advantage?'), a Latin phrase not infrequent in Cicero and elsewhere, and very common in newspaper jargon, usually in the sense of 'what's the good?'

**Cuirass**. See BREASTPLATE, ARMOUR.

**Cuirassiers** are heavy cavalry wearing the 'cuirass' and helmet. They represent the troopers of the 16th and 17th centuries, who were similarly protected. In the British army no regiments are officially styled cuirassiers, but the two regiments of Life Guards and the Royal Horse Guards were given steel cuirasses in 1821, which, however, they do not wear on active service. See GUARDS. Napoleon III. at one time maintained a bodyguard of cuirassiers, called 'Centgardes', who wore cuirasses of aluminium, much lighter than steel ones, but, like them, not proof against a rifle-bullet striking them directly.

**Cujacius**, properly JACQUES DE CUJAS or CUJAUS, jurist, born in 1522, was the son of a tanner of Toulouse. After studying law, he lectured on the *Institutes* at Cahors, Bourges, and Valence (1554–67); lived at Turin and Grenoble; and after repeated changes, finally settled in 1577 as professor at Bourges, where he resided till his death, October 4, 1590. His great reputation as a jurist was founded on a lucid exposition of Roman law, based on conscientious study of the original authorities. He had in his library 500 MSS. on Roman law, and by his emendations contributed greatly to remove the obscurities of jurisprudence. A complete collection of his works was edited by

Fabrot (10 vols. Paris, 1658), and frequently republished. See Spangenberg's *Cujacius* (1822).

**Culbin Sands**. See DRIFT.

**Culdees**, or KELDEES (Celt. *Ceile De*, 'a companion of God'; Lat. *Colidei*, *Culdei*, *Calledei*, *Keldei*, *Keledei*), the name given to an ancient order of ecclesiastics with monasteries in Scotland and Ireland, those in the former country being best known. In England and Wales only two instances of their occurrence seem to be authenticated—the first, where the canons of St Peter's at York were called Culdees in the reign of Athelstan (924–31), and the second, where Giraldus Cambrensis, writing about 1190, describes the island of Bardsey on the coast of Carnarvon as inhabited by 'most devout monks called celibates or Culdees.'

The origin and early history of these bodies is involved in almost hopeless obscurity. The name is not mentioned in the works of Adamnan, Eddi, or Bede, and makes its first appearance only about the 8th century. The conclusion at which Dr Skene arrived is 'that the Culdees originally sprang from that ascetic order who adopted a solitary service of God in an isolated cell as the highest form of religious life, and who were termed *Deicolae*; that they then became associated in communities of anchorites or hermits; that they were clerics, and might be called monks, but only in the sense that anchorites were monks; that they made their appearance in the eastern districts of Scotland at the same time as the secular clergy were introduced, and succeeded the Columban monks, who had been driven across the great mountain-range of Drumalban, the western frontier of the Pictish kingdom; and that they were finally brought under the canonical rule along with the secular clergy.'

When the Culdees appear clearly in history in the 12th century each monastery was evidently an independent community, connected with the others by no ties whatever, and owning no control except that of its own abbot, in this and other respects resembling the secular canons or monastic 'families' of England, Ireland, and the Continent in the 11th century. The monasteries seem indeed to have undergone a similar secularising process to that which took place in the Northumbrian Church after the withdrawal of the Columban clergy, when, according to Bede, false monks, under pretext of founding monasteries, purchased for themselves territories, and caused 'these to be assigned to them by royal edicts for an hereditary possession.' There seem to have been at this period two sections in each community, one still performing divine service and other religious duties pertaining properly to the body; while the other had become thoroughly lay, and so free from monastic discipline as to marry. Indeed, if a tradition of the 16th century can be received as authority for what passed in the 12th, the Culdees of Dunkeld were all married; but, like the priests of the Greek Church, lived apart from their wives during their period of service at the altar.

According to the records of the see of St Andrews, the state of the Culdee monastery there (and it may probably be taken as typical of all the rest) was in the middle of the 12th century far from satisfactory. They tell that there were thirteen Culdees holding their office by hereditary tenure, and living rather according to their own pleasure and the traditions of men, than after the rules of the holy fathers; that some few things of little importance they possessed in common; that the rest, including what was of most value, they held as their private property, each enjoying what he got from relatives and kinsmen, or from the benevolence granted on the tenure of pure friendship, or

otherwise; that after they became Culdees they were forbidden to have their wives in their houses, or any other women of whom evil suspicion could arise; that the altar of St Andrew was left without a minister, nor was mass celebrated there except on the rare occasion of a visit from the king or the bishop, for the Culdees said their own office after their own way in a corner of the church. The first attempt to reform this state of matters was made by Queen Margaret, and her efforts were followed up by her sons, Alexander I. and David I.; so that from the time of the appointment of Turgot to the see of St Andrews, when we are told that 'the whole rights of the Keledei over the kingdom of Scotland passed to the bishopric of St Andrews,' the history of the Culdees is simply that of a vain resistance to foes backed by all the weight of the royal power.

If tradition could be trusted, the first appearance of Culdees in Scotland was later than in Ireland, and should be placed about the middle of the 9th century. A leaf of the Register of St Andrews, written about 1130, relates that Brude, the son of Dergard, the last king of the Picts (who ceased to reign about 843), gave the island, since called St Serf's Inch, in Lochleven, to God, St Servan, and the Culdee hermits serving God there. They were governed by an abbot; and about the year 1093, during the rule of Abbot Ronan, they gave up their island to the Bishop of St Andrews on condition that he should find them in food and raiment. On this island they remained in peace, receiving grants of lands or immunities from all the kings of the Scots from the time of Macbeth till that of David I.; but in 1144, Robert, Bishop of St Andrews, gave their island, and all their possessions, including their church vestments and their books (a complete list of which is given in the charter), to the newly-founded Canons Regular of St Andrews, in order that a priory of that rule might supplant the old abbey of Culdees on St Serf's Inch. The bishop's grant was enforced by a charter from King David, in which it was ordered that such of the Culdees as chose to live canonically and peacefully under the new canons should remain in the island. We hear no more of the Culdee hermits of Lochleven.

The Culdees of St Andrews were of more importance than those of Lochleven, and when the Canons Regular were established there, the members of the older body were treated much more considerably than their unfortunate brethren of St Serf's Inch, those who refused to become Canons Regular being allowed to retain a liferent of their revenues. Not only was this so, but they had sufficient influence to manage to remain a distinct community down to the early part of the 14th century, and were even able to assert their right to take part in the election of the bishop till 1273. In that year they were excluded under protest, and in 1332 they were excluded entirely, and thereafter the name seems to have disappeared.

The Culdees of the church of St Mary at Monymusk, in Aberdeenshire, appear to have been settled by the Bishop of St Andrews towards the end of the 11th century. In the beginning of the 13th century they are found making a claim to be regarded as Canons Regular, which was, after an appeal to Rome, settled by a compromise.

Culdees are found at Abernethy, in Strathearn, about 1120. In the end of that century part of their possessions passed to their hereditary lay-abbot (the founder of the noble family of Abernethy), and in 1273 they were transformed into Canons Regular. After a similar division at Brechin, the prior and his Culdees were absorbed into the chapter of the new bishopric, founded by King David I. about 1145, and in less than a hundred years the name of Culdee disappears. The same

143

silent change of Culdees into secular canons took place during the 13th century at Dunblane, at Dunkeld, at Lismore, at Rosemarkie, and at Dornoch. At Dunkeld, as at Brechin and at Abernethy, great part of the Culdee revenues was held by a lay-abbot, whose office was of such mark as to be hereditary in the royal family. The father of 'the gracious Duncan,' and the son of St Margaret, were Culdee abbots. Culdees are found holding land at Monifieth, near Dundee, about 1200; at Muthil, in Strathearn, in the beginning of the 13th century; and at Iona in the middle of the 12th.

The Culdees of Armagh, dissolved at the Reformation in 1541, were resuscitated for a brief space in 1627. Their old possessions—among which were seven town-lands, containing 1423 acres, seven rectories and four vicarages, were in 1634 bestowed upon the vicars-choral of the cathedral. There were at least seven other houses of Culdees in Ireland—viz., at Clonmacnois, Clondalkin, Devenish, Clones, Popull, Monanincha, and Sligo.

Such is a concise recapitulation of all that is certainly known of the Culdees. Before their history was ascertained, opinions were held regarding them which now find few if any supporters among archæologists. It was believed that they were our first teachers of Christianity; that they came from the East before corruption had yet overspread the church; that they took the Scriptures for their sole rule of faith; that they lived under a form of church-government approaching to Presbyterian parity; that they rejected prelacy, transubstantiation, the invocation of saints, the veneration of relics, image-worship, and the celibacy of the clergy; and that they kept their simple worship and pure doctrines undefiled to the last, and were suppressed only by force and fraud, when the Roman Catholic Church triumphed over their older and better creed. For all this it is now clearly seen that there is no foundation.

See Reeves, in the *Proceedings of the Royal Irish Academy* for 1860, and his *Culdees of the British Islands* (1864); and Skene's *Celtic Scotland*, vol. ii., whose views have found acceptance both with Catholics and Presbyterians. The old views (controverted by Pinkerton and Chalmers) will be found in Selden's preface to the *Decem Historie Anglicanæ Scriptores*, and Jamieson's *Historical Account of the Ancient Culdees* (1811). Williams in his *History of Early Christianity in Britain* (1912) maintains that the Culdees were originally Celtic monastics who adhered to the early British polity, and refused to adopt the Roman system.

**Culenberg**, or **KULENBURG**, a town of Holland, 11 miles SSE. of Utrecht, on the left bank of the Lek, which is crossed here by a railway viaduct 1420 yards long; pop. 10,000.

**Culiacán**, an ancient city of Mexico, on the Río de Culiacán, 30 miles from the W. coast, and capital of the state of Sinaloa; pop. 14,000.

**Culilawan Bark**, also called **CLOVE BARK**, an aromatic bark, the product of the *Cinnamomum Culilawan*, a tree of the same genus with the Cinnamon (q.v.) tree, growing in the Molucca Islands. It has an odour resembling that of nutmeg and cloves, and was formerly employed to some extent for cases of indigestion, diarrhoea, &c.

**Cullen**, a fishing-town of Banffshire, on the Moray Firth, 67 miles NW. of Aberdeen by railway (1885). Backed by the conical Bin Hill (1050 feet), it has a harbour formed in 1817-34, and a cruciform parish church, which was founded by Robert Bruce, whose second queen died here, and which in 1543 was made collegiate. Cullen House, a seat of the Earl of Seafield, is a Scottish baronial pile, enlarged and remodelled in 1861. Cullen has been a royal burgh since about 1200, and till 1918 (when it was merged in the county)

united with Elgin and five other burghs to return one member to parliament. Pop. 2000.

**Cullen, PAUL**, a great Irish churchman, was born near Ballitore, in County Kildare, April 27, 1803. After a brilliant course in the Collegio Urbano of the Propaganda at Rome, he was ordained priest in 1829, and filled in succession the offices of vice-rector and rector of the Irish College in Rome, and rector of the Propaganda College. During the period of Mazzini's power in Rome in 1848, Cullen astutely saved the property of his college by placing it under American protection. At the close of 1849 the three names sent up to the pope having been passed over, Cullen unexpectedly found himself nominated to the archbishopric of Armagh and primacy of Ireland. He was consecrated early in the following year, and at once commenced a vigorous and uncompromisingly ultramontane reign of eight-and-twenty years, in which he established lasting memorials to his memory in new churches, schools, convents, and hospitals, such as the Mater Misericordiae. He denounced mixed education in every form, and from the outset opposed all revolutionary and anti-constitutional opposition to the crown. His vigorous denunciations of Fenianism made him many enemies among the more hot-headed Irishmen, but greatly increased the respect of English Protestants for a church that would make no terms with crime, even when committed by its own children. At the Synod of Thurles in 1851, principally by Cullen's persuasion, the establishment of a Catholic university in Ireland was recommended. Translated to Dublin in 1852, he was created a cardinal priest in 1866, the first Irishman who had reached that elevated rank. One of the majority at the Vatican Council, he long enjoyed the familiar friendship of Pope Pius IX. He died at Dublin soon after his return from a journey to Rome, October 24, 1878.

**Cullen, WILLIAM, M.D.**, physician, was born at Hamilton, Lanarkshire, on 15th April 1710, his father being factor to the Duke of Hamilton. After learning his profession, first as apprentice to a surgeon-apothecary in Glasgow, next as surgeon on board a West Indian trading ship, and then as assistant to an apothecary in London, he returned to Scotland in 1731, and commenced practice in his native county. Feeling the necessity of more systematic study, he spent two winters at Edinburgh University under Munro primus, and then removed to Hamilton, where he soon secured a good practice. One of his articulated pupils was William Hunter (q.v.), to whom he became extremely attached; and it was agreed that one of them should be alternately allowed to study during the winter, while the other carried on the practice. Cullen spent the first winter at Edinburgh, and it is at this time that he appears to have taken an important part in founding what is now known as the Royal Medical Society. It being Hunter's turn next year he went to London, and having attracted attention there, did not return, Cullen generously cancelling the articles. In 1740 Cullen graduated M.D. at Glasgow University, gave up surgical work, and soon after established himself in Glasgow as a physician. At that time there was not in Glasgow any regular course of medical study, and Cullen occupied himself much in the foundation of a medical school, himself lecturing on various subjects. One of his pupils was the famous Dr Joseph Black (q.v.). Cullen's labours resulted in his appointment to the chair of Medicine in the university, which he occupied four years. In 1755 he was persuaded to leave Glasgow for Edinburgh, and for the next thirty-five years was one of the mainstays of the Edinburgh medical

school. During this long period he occupied successively the chairs of Chemistry, Institutes of Medicine, and Medicine, besides teaching clinically in the Royal Infirmary all the time.

Living as he did in what might be termed the renaissance period of the history of medicine, Cullen was essentially a man of his time, and did much to advance the science. For many centuries all disease had been referred to disorders of the fluids of the body. Just before Cullen's time, Boerhaave had added to this a pathology of the 'fibres' still strongly tinged with the old fluid or humoral pathology. To Cullen is largely due the recognition of the important part played by the nervous system both in health and disease. He denied the theory supported even by Boerhaave, that the brain was an excretory organ and the nervous influence a fluid. Many of his speculations as to reflex nervous action, the possible presence in a single nerve of both sensory and motor fibres, and the connection of sensory and motor nerves with the anterior and posterior nerve roots, have now been proved to be facts. He had a singularly open and candid mind, and while himself introducing the use of several new drugs, as oxide of antimony and tartar emetic, was careful to distinguish between the action of drugs and the curative operations of nature. It may be said of him in his own words when speaking of Sydenham, 'that he rather sought for theory to connect his facts, than for facts to support his theory.'

In the later years of his life arose the controversy on the Brunonian system (see BROWN, JOHN, M.D.), which system Cullen bitterly opposed. Brown's specious division of diseases into sthenic and asthenic was obviously a deduction from Cullen's theories of nerve influence, and was only one instance out of many where a reputation was built on ideas borrowed from Cullen.

Cullen died on 5th February 1790 at his small estate of Ormiston Hill, having nearly completed his seventy-ninth year, and having been actively engaged in teaching and consulting practice till within a few months of his death. Cullen's most important works are *First Lines of the Practice of Physic* (Edin. 1777), *Synopsis Nosologiae Methodicae* (1785), *Institutions of Medicine* (1777), *A Treatise on the Materia Medica* (1789). See Biography, vol. i. by Dr John Thomson (1832), vol. ii. by Cullen's son and Dr David Craigie (1859), also an article by Sir W. Hamilton in the *Edinburgh Review* (1831).

**Cullera**, a town and port of Spain, near the mouth of the Jucar, 25 miles SSE. of Valencia. It exports rice, pistachio-nuts, oranges, wine, and oil. Pop. 13,000.

**Cullod'en**, or DRUMMOSSIE MUIR, a broad flat sandstone ridge, 300 to 500 feet high, 6 miles ENE. of Inverness. Planting and culture have changed its aspect much since 16th April 1746, when it was the scene of the total rout of 5000 Highlanders under Prince Charles Edward by 12,000 regulars under the Duke of Cumberland. Since 1881, a cairn, 20 feet in height, with an inscription, marks the spot where the battle was fiercest, and where many of the slain lie buried. Within 2 miles stands Culloden House, the seat of Duncan Forbes and his descendants.

**Culm**, a kind of impure Anthracite (q.v.). In some districts the culm obtained from the pits in a broken and crumbling condition is used as fuel, being made up into balls, with one-third of its bulk of wet viscid clay. It burns without flame, producing a strong and steady heat, well adapted for cooking (see BRIQUETTES). The term *Culm-measures* is applied to the carboniferous strata of Devonshire, on account of the workings for culm near Bideford, and other places.

**Culm**, the peculiar cylindrical hollow and jointed stem of Grasses (q.v.).

**Culmination**, an astronomical term, signifying the passage of a star across the meridian. The star is then at the highest point (*culmen*) of its course; hence the name. The sun culminates at mid-day, or twelve o'clock, apparent solar time—which seldom agrees exactly with mean time, as shown by a watch or clock. The full moon culminates at midnight.

**Culna**. See KALNA.

**Culpa** simply means fault (generally the omission of some act) which leads to legal liability for the immediate consequences. It may arise under a contract, especially where many of the obligations of the parties are left to implication—e.g. in the contract of carriage of passengers; or from the mere relative position of parties, as where a member of the public, or a neighbour, is injured by the negligent use of property. The distinction between culpa and breach of contract, while theoretically clear, is practically difficult; and accordingly the opinion of a jury is constantly required to ascertain whether fault has been committed in the execution of a contract.

**Culpable Homicide**. See MANSLAUGHTER, and MURDER.

**Culpeper, JOHN**. See COLEPEPER.

**Culpeper, NICHOLAS**, was born in London in 1616, and after studies at Cambridge and elsewhere, started in 1640 to practise astrology and physic in Spitalfields. In 1649 he published an English translation of the College of Physicians' Pharmacopœia under the title *A Physical Directory, or a Translation of the London Dispensatory*, renamed in 1654 as *Pharmacopœia Londinensis, or the London Dispensatory*. This infringement upon a close monopoly, together with his sturdy and uncompromising support of Puritanism and the parliament, brought Culpeper many enemies and much obloquy. In 1653 he published *The English Physician Enlarged*. Both books had an enormous sale, and both are included in Dr Gordon's collective edition of his Works (4 vols. 1802). Culpeper wrote numerous other books, many of which were left unprinted, and died worn out before his time, 10th January 1654.

**Culpeper, SIR THOMAS**, was born of good Kentish family in 1578. He studied at Hart Hall, Oxford, and at one of the Inns of Court, next bought Leeds Castle in Kent, where, or at Greenway Court, near Hollingbourn, he mostly lived till his death, which took place in 1662. He was knighted by James I. in 1619. His *Tract against the high rate of Usury*, published in 1621, contended for the reduction of interest to six per cent.—His third son, SIR THOMAS CULPEPER, born in 1626, made his studies at University College, Oxford, and after making the grand tour, and being knighted soon after the Restoration, retired to his estate of Greenway Court, where he died in 1697. Besides editing and prefacing his father's treatise on exorbitant usury in 1668, he himself published many pamphlets on the same subject, repeating his father's arguments. He wrote also *Essays or Moral Discourses on several Subjects* (1655 and 1671).

**Culross**, an old-world village of Fife (till 1890 in a detached portion of Perthshire), on the north shore of the Firth of Forth, 7 miles W. by S. of Dunfermline. With memories of St Serf and St Kentigern, James VI., and the Elgin and Dundonald families, it has a Cistercian abbey (1217, restored 1906), but has lost its manufacture of girdles, its salt-works, shipping, and submarine coal-mines. A royal burgh since 1588, it united till 1918 with Stirling and

three other towns to return one member to parliament. Pop. 500. See Beveridge's *Culross and Tulliallan* (1885).

**Cultivated Plants**. That the history of material progress is directly connected with and measured by man's increasing utilisation of the vegetable and animal, no less than of the mineral world, is an idea of common experience, which the researches of archaeologists in all parts of the world have amply confirmed. The whole subject forms, indeed, one of the most fascinating aspects of the history of civilisation. Primitive man, acquiring his acquaintance with useful plants by slow and often bitter individual experience at the very margin of subsistence, offers a striking contrast with the experimental organiser of new and in every sense remotely productive cultures like that of the cinchona-tree in the Himalayas,—a contrast which spans the whole range alike of the practical resources and the scientific culture of the human race.

Without speculation as to the precise steps by which man passed from the hunting or merely pastoral to the agricultural state, we find positive evidence of the existence of agriculture long before written records. Thus, though the 'kitchen-middens' of northern countries contain no trace of cultivated plants, the deposits of Swiss lake-dwellings have yielded remains of fruits, of cereal and other seeds, and of linen fabrics, showing the existence of a considerable agriculture before the use of metals. Ancient traditions and ceremonials of China also bear witness to the remoteness of cultivation there. The earliest Egyptian picture-writings and the greater number of cultivated species have arisen in that central cradle of civilisation which may be broadly marked off by drawing lines from the delta of the Nile to the head of the Persian Gulf, and from the Dardanelles to the Caspian—i.e. between 30° and 40° lat. From this region the majority of European plants are derived. Another great centre of ancient agriculture, however, is China; while the third is intertropical America, where the ancient Mexicans and Peruvians practised the culture of not a few plants, of which some have become almost cosmopolitan since the epoch-making voyage of Columbus.

Since the rise of modern botany (see BOTANY), our knowledge of species at least possibly useful has been greatly extended, yet there seems little risk of displacement of the established cereals, fruit-trees, &c., since these have the advantage of an enormous past of artificial selection, which has in many cases practically transformed them into new species, apparently distinct from their wild congeners, and incapable of continued existence in the uncultivated state—e.g. wheat, barley, maize, pea, sugar-cane, yam, &c., and probably also bean, tobacco, manioc, &c. Moreover, such long cultivated plants usually exhibit greater variability than naturally wild species, and thus in every way new cultures tend to be unremunerative. Hence the majority of species of primary nutritive importance to man at present are among those which have been in cultivation for the past 2000 years; and the progress which is now being made is essentially on lines which merely supplement these; the newer plants, cultivated for less than 2000 years, being, according to De Candolle, chiefly artificial fodders, which the ancients scarcely knew; then bulbs, vegetables, medicinal plants (cinchona); plants with edible fruits or nutritious seeds (buckwheat), or aromatic seeds (coffee). Here, of course, the demand for variations in food and drink, for narcotics and medicines, for textiles and timber, all combine towards progress; in most of these the demand is at bottom more largely æsthetic than utilitarian,

while this becomes exclusive in the newest but extending department of flower gardening.

See the articles AGRICULTURE, GARDENING, FRUIT, PASTURE, PLANTS (MEDICINAL), &c.; those on special plants—e.g. BARLEY, COCA, DATE, MAIZE, &c.; also De Candolle, *Origin of Cultivated Plants* (Inter. Sc Series, 1884); and Hehn's *Wanderings of Plants and Animals* (1886).

**Cultivator**, a farm implement. See GRUBBER.

**Culverin**, one of the earlier forms of Cannon (q.v.), of great length, generally an 18-pounder, weighing 50 cwt.; the *semi-culverin* being a 9-pounder, weighing 30 cwt.

**Culver's Root**, the rhizome of *Veronica virginica*, used medicinally as *radix leptandree* of U.S. Pharmacopoeia.

**Culvert** is the name given to an arched channel of masonry for the conveyance of water underground or beneath an embankment.

**Culverwel**, NATHANAEL, one of the Cambridge Platonists, was born in Middlesex, and entered Emmanuel College in 1633. He graduated B.A. in 1636, M.A. in 1640, was elected fellow in 1642, and died not later than 1651. In 1652 was published *An Elegant and Learned Discourse of the Light of Nature*, with several other treatises—viz. the Schism, the Act of Oblivion, the Child's Return, the Panting Soul, Mount Ebal, the White Stone; *Spiritual Optics*; and the *Worth of Souls*. An edition of the *Light of Nature* was issued in 1857, edited by Dr John Brown of Edinburgh, with a critical essay by Principal Cairns. It is a treatise of great power and learning, written in a vivid and vigorous style, and is a work not unworthy of the college of Cudworth, Whichcote, and John Smith. See Tulloch's *Rational Theology*, vol. ii. (1874), and Campagnac's *Cambridge Platonists* (1902).

**Cumæ**, an ancient city on the coast of Campania, probably founded conjointly on an ancient site by Chalcians from Euboea, and Æolians from Cyme in Asia Minor. The date of its foundation is uncertain, but according to Strabo it was the earliest of all the Greek settlements either in Italy or Sicily. It soon attained to wealth and power, built several harbours or port-towns of its own, kept a tolerably large fleet, extended its influence over the native tribes of the neighbouring territories, planted colonies in Italy and Sicily, at Puteoli, Neapolis, and Zancle (Messina). Spite of attacks from the Etruscans and Umbrians without, and dissensions within, for the two hundred years before 500 B.C. it was the most important and civilised city in Southern Italy. In 474 its ally, Hieron, king of Syracuse, defeated the combined fleets of the Etruscans and Carthaginians, who had attacked it by sea. Cumæ at length lost its independence (417 B.C.) when it was conquered by the Samnites, who killed or enslaved most of the citizens. It ultimately became a Roman municipium and colony, but continued to decline. It re-assumed a momentary importance during the wars of Belisarius and Narses. Its strong fortress, garrisoned by the Goths, was the last place in Italy that held out against the Byzantine army. Cumæ is famous as the residence of the Sibyl (q.v.), whose cave was identified with one of the many subterranean passages in the rock on which the citadel stood. Most of these are now choked up. See for excavations E. Gabrici, *Cuma* (Acc. dei Lincei, 1913, &c.).

**Cumaná**, a town in the north of Venezuela, on the Manzanares, a mile above its mouth, where the port of Puerto Sucre lies on the Gulf of Cariaco. It has a national college, and some export trade, but is chiefly of interest as the oldest European town on the South American mainland, having been founded by Christopher Columbus's son Diego

as New Toledo c. 1521. It has suffered much from earthquakes, and was almost entirely destroyed in 1853. Population, 16,000.

**Cumania**, a region in eastern and central Hungary divided into *Great Cumania*, east of the Theiss, and *Little Cumania*, between the Danube and the Theiss, now incorporated in the adjoining Hungarian provinces. The inhabitants, the Cumans, are the descendants of a race of nomad invaders of the Turkish stock, who forced their way into Hungary from beyond the Volga in the 11th century. They long held their own in alternate alliance and war with the surrounding states. They maintained their heathenism and their barbarous customs, till in 1278 a crusade was proclaimed against them by Pope Nicholas IV., and they were compelled to accept Christianity and adopt the ways of their Magyar neighbours. They are now wholly Magyarised.

**Cumberland**, a Border county of England, washed on the W. by the Irish Sea and the Solway Firth, and elsewhere bounded by Dumfries and Roxburgh shires, Northumberland, Durham, Westmoreland, and Lancashire. Eleventh in size of the English counties, it has a maximum length of 75 miles, a maximum breadth of 45, a coast-line of 75, and an area of 1520 sq. m. The surface is mountainous in the south-west and east; the middle consists of hills, valleys, and elevated ridges; and the north and north-west districts, including the vale of Carlisle, are low, flat, or gently undulated. The mountains in the south-west are high, rugged, and sterile, with deep and narrow valleys, lakes, rivers, waterfalls, and woodlands. The chief mountains are Scaw Fell Pike (3210 feet), Scaw Fell (3162), Helvellyn (3118), Skiddaw (3058), Bow Fell (2960), and Cross Fell (2892). The largest lakes are Ullswater, Derwentwater, Bassenthwaite, Crummock Water, Thirlmere, Buttermere, Wastwater, and Ennerdale. Six of the chief waterfalls are 60 to 156 feet high. The chief rivers are the Eden, the Esk, and the Derwent. The Lancaster and Carlisle railway route from London to Edinburgh crosses the north-east part of Cumberland.

The Lake district, or nearly the south-west half of Cumberland, consists of Silurian slates, with protrusions of granite and trap rocks, and with New Red sandstone along the coast south of St Bees Head. In the north is a semicircular strip of carboniferous limestone; then follow strips of coal strata and Permian rocks; then the new red sandstone plain of Carlisle, with carboniferous limestone on the north-east, including a trap-dike 30 miles long. Cumberland abounds in mineral wealth—silver, copper, lead, iron, zinc, plumbago, gypsum, limestone, coal, slates, marbles, marl, and several of the rarer minerals are or have been worked.

In the mountainous parts the climate is wet and variable, especially from July to October; on the coast it is mild. There is an annual rainfall of 50 inches at Whitehaven, and of 59 at Keswick; while at Styhead Pass, at an altitude of 1077 feet, the rainfall has been as much as 243·98 inches. Half of the cultivated soil consists of dry loam. Much of the subsoil is wet clay. The chief crops are wheat, barley, oats, turnips, and potatoes. There are many small dairies. Sheep and cattle are reared in the mountains. The estates are generally small, and farmed by the owners, or held under the lords of the manors by customary tenure. Many of the small proprietors, or 'statesmen,' have had their lands in their families for centuries, and have a high spirit of independence. There are manufactures of woollens—much being domestic—cottons, linens, earthenware, and glass. The chief towns are Carlisle, Cockermouth, Whitehaven, Workington, Maryport, Wigton, Penrith, Keswick,

Egremont. Since 1918 Cumberland has returned one member for each of the four divisions—Northern, Penrith and Cockermouth, Whitehaven, and Workington. Pop. (1801) 117,230; (1841) 178,038; (1871) 220,253; (1901) 266,921; (1921) 273,037. Near Keswick and Kirkoswald are two fine stone circles; and many Roman relics have been found, such as altars, coins, and inscriptions. For centuries part of Cumbria or Strathclyde, the present county was finally annexed to England in 1157. For three hundred years prior to the union of the crowns it was the constant scene of war and devastation, from incursions of the English and Scots; and it suffered again in both the '15 and the '45. Cumberland has many old crosses, and remains of some monasteries and hospitals; and on the Border, many towers or peel-houses. See **BORDERS, LAKE DISTRICT**; R. S. Ferguson's *History of Cumberland* (1890); and the 'Victoria History' (1901, *et seq.*).

**Cumberland**, a river, rises in Kentucky, flows into Tennessee, and returning to Kentucky, enters the Ohio at Smithland, after a course of about 650 miles, of which nearly 200 are navigable for steamboats.—For Cumberland Mountain, see **APPALACHIANS**.

**Cumberland**, capital of Allegany county, Maryland, on the Potomac River, 120 miles W. by N. of Baltimore. It is a canal terminus and an important railway centre; manufactures iron and steel, brick, cement, flour, and leather; and trades extensively in coal. Pop. 30,000.

**Cumberland**, DR RICHARD, was born in London, 15th July 1631. Educated at St Paul's School and Magdalene College, Cambridge, he was preferred to the rectory of Brampton, Northamptonshire, in 1658; in 1667 to the living of All Saints, Stamford; and in 1691 to the bishopric of Peterborough. Cumberland was a man of great acquirements, and of sincere and simple piety; his frequent saying, 'A man had better wear out than rust out,' explains his unusually high idea of episcopal duty. He wrote several works, of which one, perhaps, is still read, his *De Legibus Naturæ* (1672), written in reply to Hobbes, and remarkable as placing the foundation of morality on a utilitarian basis. His *Essay on Jewish Weights and Measures* was dedicated to his old college friend Pepys, as president of the Royal Society. As an instance of Cumberland's insatiable thirst for knowledge, it is mentioned that he learned Coptic after the age of eighty-three. He died 9th October 1718.

**Cumberland**, RICHARD (1732–1811), dramatic writer, novelist, and essayist, was born in the lodge of Trinity College, Cambridge. He was the great-grandson of Dr Richard Cumberland (q.v.), and grandson, by the mother's side, of Dr Richard Bentley. From Bury St Edmunds and Westminster, where he was contemporary with Cowper, Churchill, and Warren Hastings, he passed to Trinity College, Cambridge, and here was elected to a fellowship at twenty. Becoming private secretary to Lord Halifax, he gave up his intention of entering the church, and, after passing through several subordinate offices, was appointed secretary to the Board of Trade. He held that office after his return from an unfortunate secret mission to Spain (1780), which cost him as much as £5000, a sum that ministers refused to reimburse, when the Board was suppressed. Having obtained a compensation allowance of about half his salary, Cumberland retired to Tunbridge Wells, where he devoted himself to literature, and wrote incessantly farces, tragedies, comedies, pamphlets, essays, and two novels of some merit, *Arundel* and *Henry*. Many of his comedies were successful at the time of their appearance, although they have

not kept possession of the stage. Among them may here be named *The West Indian*, *The Brothers*, *The Fashionable Lover*, *The Jew*, and *The Wheel of Fortune*. Cumberland is alluded to in Goldsmith's *Retaliation* with not unkindly satire as 'the Terence of England, the mender of hearts;' in Sheridan's *Critic* he is gibbeted as 'Sir Fretful Plagiary.' His essays and translations from the Greek poets are long forgotten. His inaccurate Memoirs of himself were published in 1807. See his *Life and Dramatic Works*, by S. T. Williams (1918).

**Cumberland**, WILLIAM AUGUSTUS, DUKE OF, second son of George II., was born in 1721. He adopted a military career, was wounded at Dettingen in 1743, and defeated, not ingloriously, at Fontenoy, by Marshal Saxe, in 1745. He was next sent to crush the Young Pretender's rebellion, which he did effectually at Culloden (1746); and by a series of severe measures against the broken and dispirited Highlanders he earned for himself the lasting title of 'the Butcher,' to set off against his reward of £25,000 a year and the thanks of parliament. In 1747 he was defeated by Saxe at Lawfeldt, and in 1757 had to surrender and disarm his army at Kloster-Seven; after which he retired into private life, and died 31st Oct. 1765. See *Lives* by Rev. A. N. Campbell-Maclachlan (1876) and Hon. Evan Charteris (1913), and the latter's *Duke of Cumberland and the Seven Years' War* (1925).—For other dukes and earls of Cumberland, see **HANOVER** and **CLIFFORD**.

**Cumberland Island** (so called) is a peninsula of Baffin Land, extending into Davis Strait.

**Cumberland Presbyterians**, a religious denomination which sprang up in 1810 in the state of Kentucky, in consequence of a dispute between the presbytery of Cumberland in that state, and the Kentucky Synod of the Presbyterian Church in America, concerning the ordination of persons who had not passed through the usual educational curriculum, but whose services the presbytery regarded as demanded for the ministry by the exigencies of the times. Their form of government is presbyterian, though they have added a system of itinerating like the Methodists. Arminian in doctrine, they deny unconditional election and predestination, and believe in the universality of the atonement. A university in connection with the church was set up at Lebanon, Tennessee, in 1844.

**Cumberland Valley**. See **PENNSYLVANIA**.

**Cumbræ**, BIG or GREAT, an island of Bute-shire, in the Firth of Clyde, 2½ miles E. of Bute at the narrowest, and 1½ mile WSW. of Largs. With the shape of a shark's tooth, it is 3½ miles long, 2 broad, 10½ in circumference, and 5 sq. m. in area. It rises to a height of 417 feet, and consists of Old Red Sandstone, with wall-like dykes intersecting it. There is some fishing and a little farming. Millport, on the south shore, 19 miles SSW. of Greenock (*via* Wemyss Bay), is a crowded resort in summer, with a biological station.—**LITTLE CUMBRAE**, 1½ mile SSW. of Millport, is barely 1 sq. m. in area. It rises 409 feet, and has a lighthouse (1826).

**Cumbria**. See **CAMBRIA** and **STRATHCLYDE**; also **BRETTS**.

**Cummin**, or **CUMIN** (*Cuminum*), a genus of Umbelliferae, containing only one known species (*C. cyminum*), common in Egypt and the neighbouring countries, sometimes as an annual weed, but more frequently in cultivation, as also in southern Europe and India. It is referred to in Scripture (as in Matt. xxiii. 23). The fruit-lobes separate in the way characteristic of the order, and are thus popularly called seeds; their odour and properties resemble those of Caraway (q.v.),

but are stronger, and therefore to some palates more pleasant. It is employed as a carminative flavouring in many parts of the world; but its strictly medicinal use (as in plasters) is now chiefly confined to veterinary practice. In Germany, it is often put into bread; in Holland, sometimes into cheese. It contains a peculiar volatile oil (*Oil of Cummin*). Cummin-seed is brought to Britain mostly from Sicily and Malta.—The fruit of *Lagoeia cuminoides*, another umbelliferous plant, a native of the Levant, is similar in its qualities and uses to that of cummin. For the Black Cummin of the ancients, see NIGELLA.

**Cumming**, CONSTANCE FREDERIKA GORDON (1837–1924), was born at Altyre, a sister of the lion-hunter (see below). Her sprightly and entertaining volumes include *From the Hebrides to the Himalayas* (1876); *At Home in Fiji* (1881); *A Lady's Cruise in a French Man-of-war* (1882); *Fire Fountains—Hawaii* (1883), books on China (1885), and Ceylon (1891), an account of W. H. Murray, inventor of numeral type for the use of blind and illiterate Chinese (1898), and *Memories* (1904).

**Cumming**, JOHN (1807–81), divine and author, was born in Fintray parish, Aberdeenshire. He took his M.A. at King's College, Aberdeen, in 1827, and in 1832 was ordained to the Scotch Church, Crown Court, Covent Garden, London, where he preached with great popularity and success till 1879. Edinburgh University gave him the degree of D.D. in 1844. He was active in philanthropic projects, and as a controversialist and lecturer both against the party that formed the Scottish Free Church and in the 'anti-Popery' cause; but his celebrity was chiefly due to his writings on the interpretation of prophecy. His audacity in this perilous enterprise drew upon him much ridicule. In 1868 he asked the pope if he might attend the Oecumenical Council, but his application was declined through Archbishop Manning. His works number over a hundred. Among them are *Apocalyptic Sketches* (three series, 1848–50), *Prophetic Studies* (1850), *Signs of the Times* (1854), *The Millennium Rest* (1862), *Ritualism the Highway to Rome* (1867), *The Sounding of the Last Trumpet* (1867), and *The Seventh Vial* (1870).

**Cumming**, ROUALEYN-GEORGE GORDON, the African lion-hunter, was born 15th March 1820, and educated at Eton. He became a cornet in the Madras Cavalry in 1838, served for a time in Canada, and joined the Cape Mounted Rifles in 1843; but he soon resigned his commission, and, till his return to England in 1848, engaged in those famous exploits narrated in his *Five Years of a Hunter's Life* (1850); abridged as *The Lion-hunter of South Africa*, (1858). He died 24th March 1866.

**Cummings**, BRUCE FREDERICK ('W. N. P. Barbellion,' 1889–1919), English naturalist and author, was a native of Devonshire, and became assistant, first at the laboratory of the British Marine Biological Association at Plymouth, and later at the British Museum of Natural History, South Kensington. In 1914 illness, necessarily fatal, ended his promising career as a zoologist, but afforded leisure for literature, and in 1919 appeared his *Journal of a Disappointed Man*, a realistic account of his life, distinguished in style, and a mingling of bitterness and humour. *Enjoying Life* (1919) and *A Last Diary* (1920) were published posthumously.

**Cummins**, MARIA SUSANNA (1827–66), American novelist, born at Salem, Massachusetts, wrote for the *Atlantic Monthly* and other magazines. Her first novel, *The Lamplighter* (1854), had a prodigious sale. Her other books include *Mabel Vaughan* (1857), *El Fureidis* (1860), and *Haunted Hearts* (1864).

**Cumnock**, OLD, a town of Ayrshire, on Lugar Water, 18 miles by rail E. of Ayr, and 43 NW. of Dumfries. The manufacture of wooden snuff-boxes was many years since transferred to Mauchline, and mining is now the chief industry. The Covenanting 'prophet,' Peden (1626–86), lies in the churchyard. Dumfries House, a seat of the Marquis of Bute, is 2 miles W. Pop. (Cumnock and Holmhead police burgh), 3500.—NEW CUMNOCK, on the Nith, is 5½ miles SE. of Old Cumnock.

**Cumulative Voting**. See REPRESENTATION.

**Cunard**, SIR SAMUEL, was born 21st November 1787 at Halifax, Nova Scotia, where his father, a Philadelphia merchant, had settled. Becoming early a successful merchant and shipowner, Cunard came to England in 1838, joined with George Burns, Glasgow, and David M'iver, Liverpool, in founding (1839) the British and North American Royal Mail Steam Packet Company, and obtained a contract from the British government for the mail service between Liverpool and Halifax, Boston, and Quebec. The first passage was that of the *Britannia* in 1840, the time occupied being fourteen days eight hours. Iron steamers were first used in 1855, and paddle-wheels gave way entirely to the screw after 1862. From its small but successful beginning, Cunard's undertaking soon developed into one of the vastest of private commercial concerns. In 1878 it was made into a joint-stock company. Created a baronet in 1859, Cunard died at London, 28th April 1865.

**Cunaxa**, in Babylonia, east of the Euphrates, about 60 miles N. of Babylon, noted for the battle (401 B.C.) between Cyrus the younger and his brother Artaxerxes Mnemon, in which the former was killed.

**Cundinamarca**, a department of Colombia, extending east to Venezuela. It was the second largest department of the republic, but was reduced in 1905 from 80,000 to 5000 sq. miles, and disappeared in the new territorial division of 1908. In 1909 it was restored with about 8000 sq. miles. The western part is mountainous, with fertile valleys and plateaus; in the east are vast plains. It is well wooded, rich in minerals, and famous for its Bogotá coffee. Pop. 812,000. The capital is Bogotá (q.v.), also capital of the republic.

**Cuneiform**, Cuneatic, Wedge-shaped, Arrow-headed (Fr. *tête-à-clou*, Arab. *mismari*), are terms for a certain form of writing, of which the component parts are wedges. It was used by the ancient peoples of Sumer, Akkad, Babylonia, Assyria, Elam, and Persia; and was inscribed upon stone, bronze, iron, glass, and clay. Cuneiform inscriptions were chiselled upon stone and iron, but they were impressed upon soft clay with a pointed stylus having three unequal facets, the smallest to make the fine wedge of the cuneiform signs, the middle-sized to make the thicker wedges, and the largest to make the outer and thick wedges of the characters. The first date that can be assigned to the use of cuneiform writing is about 4000 B.C., and its use was continued until after the birth of Christ. One of the earliest inscriptions at present known is that inscribed upon the porphyry mace-head of Shar-gali-Sharri I. of Agade; the latest is a tablet preserved at Munich, which may have been written about 83 A.D. Cuneiform writing was widely used in Elam, Babylonia, and Assyria, whence it spread to the districts north of Nineveh. For nearly 1600 years after its extinction its very existence was forgotten. The immense ruins found all over Persia, and especially those of ancient Persepolis, had at all times attracted the attention of eastern travellers; still no one seems to have dreamed that those strange wedges which com-

pletely covered some of them could have any meaning. It was Garcia de Sylva Figueroa, ambassador of Philip III. of Spain, who, on a visit to Persepolis in 1618, first became possessed with the firm conviction that these signs must be inscriptions in some lost writing and, perhaps, language, and had a line of them copied. Amongst subsequent travellers whose attention was attracted to the subject, Chardin, after his return to Europe in 1674, published three complete groups of cuneiforms, copied by himself at Persepolis, together with a comparatively long and minute account of the mysterious character. He likewise declared it to be 'writing and no hieroglyphs: the rest, however, will always be unknown.' Michaux, a French botanist, in 1782 sent from Bagdad to Paris a boundary stone covered with Babylonian cuneiforms. Ever since, the materials for the investigation of a subject the high importance of which by that time was fully recognised have been rapidly accumulating. Sir H. Jones, Ker Porter, Robert Stewart, Sir W. Ouseley, Bellino, Di Schultze—up to Rich and Botta, Flandin, Rouet, Rawlinson, Layard, Oppert, Smith, Rassam, Budge, King, Hall, Woolley, and Sydney Smith, each in his turn brought back more or less valuable materials from his eastern travels; and, naturally enough, those explorers were among the foremost to engage in the study of the records they had brought to light.

Now that we are able to explain so much of these inscriptions, it is highly interesting and instructive to notice the opinions first entertained of them by the wise and learned in Europe. In the *Transactions of the Royal Society of June 1693*, they first appeared from a copy made by Flowers, and they are held to be 'the ancient writing of the Gaures or Gebres.' Thomas Hyde, the eminent Orientalist, declared them, in his learned work on the religion of the ancient Persians (1700), to be nothing more or less than idle fancies of the architect, who endeavoured to show how many different characters a certain peculiar stroke in different combinations could furnish. Witte, in Rostock, saw in them the destructive work of generations upon generations of worms. Generally, they were pronounced to be talismanic signs, mysterious formulæ of priests, astrological symbols, charms which, if properly read and used, would open immense vaults full of gold and pearls—an opinion widely diffused among the native savants. The next step was to see in them a species of revealed digital language, such as the Almighty had first used to Adam. Lichtenstein read in some of them certain passages from the Koran, written in Kufic, the ancient Arabic character; in others, a record of Tamerlane; and was only surprised that others should not have found this, the easiest and clearest reading, long before him. Kämpfer was not quite sure whether they were Chinese or Hebrew characters. That they were Runes, Oghams, Samaritan, or Greek characters, were some of the soberest explanations.

It was Karsten Niebuhr who first showed the way, to the more sensible portion of the learned, out of this labyrinth of absurdities. Without attempting to read the character itself, he first of all established three distinct cuneiform alphabets instead of one, the letters of which seemed to outnumber those of all other languages together. The threefold inscriptions found at Persepolis he rightly took to be transcripts of the same text in three alphabets, in a hitherto unknown language. Tychsen of Rostock (1798), and Münter of Copenhagen (1800), affirmed and further developed this conjecture. The latter went so far as to divide the characters and inscriptions into alphabetical, syllabic, and monogrammatical, and to assume two different languages—Zend for inscriptions of a religious, Pehlevi for those of a political character.

The real and final discovery, however, is due to Grotefend of Hanover, and dates from 1802. On the 7th of September of that year he laid the first cuneiform alphabet, with its equivalents, before the Academy of Gottingen—strangely enough, in the very same sitting in which Heyne gave an account of the first reading of hieroglyphs. The process by which Grotefend arrived at that wonderful result is so supremely interesting, that we cannot omit to sketch it briefly. He fixed upon a Persepolitan inscription of what was called the first class, and counted in it thirty promiscuously recurring groups or combinations of cuneiforms. These groups he concluded to be letters, and not words, as a syllabary of thirty words could not be thought of in any language. Then, again, a certain oblique wedge, evidently a sign of division, which stood after three, four, five, up to eight or nine such groups or letters, must show the beginning or end, not of a phrase, but of a word. Tychsen and Münter had already pointed out a certain combination of seven characters as signifying the royal title. Grotefend adopted this opinion. The word occurred here and there in the text, and after the first words of most of the inscriptions, twice; the second time with an appendage, which he concluded to be the termination of the genitive plural, and he translated these two words, without regard to their phonetic value, 'King of Kings.' He then, in comparing the words preceding the royal titles in two tablets, found them repeated in what he assumed to be a filial relation; thus: There were three distinct groups, words, or names, which we will call X, D, and H, and this is how they occurred: (1) X, King of Kings, son of D, King of Kings; (2) D, King of Kings, son of H; but the (3) H was *not* followed by the word King. H, therefore, must have been the founder of the dynasty. Now the names themselves had to be found. Grotefend, unlike his predecessors, had recourse not to philology, but to archaeology and history. The inscriptions in question were by that time proved to belong to the Achaemenian dynasty, founded by Hystaspes = group H. He was followed by Darius, 'King of Kings, son of Hystaspes,' or Darius Hystaspes = group D; he, again, by Xerxes, King of Kings, son of Darius, King of Kings = group X—and the problem was solved. It could not have been Cyrus and Cambyses, as the groups did not begin with the same signs (C); nor Cyrus and Artaxerxes, the first being too short for the group, the second too long—it could only be Darius, Xerxes, Hystaspes—of course in the orthography of their, not of our time; and wherever in these names the same letters recurred, they were expressed by the same combinations of signs. A further proof of the correctness of the reading was furnished by a vase in Venice, bearing a cuneiform and a hieroglyphical inscription, which were both read at the same time independently: 'Xerxes.' Innumerable difficulties, however, remained, and remain up to this moment. Grotefend had, after all, only read—and not altogether correctly—three names, which did not contain more than twelve letters—the rest being mere conjecture—and there were many more in this alphabet. The other two alphabets, with an infinite variety of letters, had hardly been properly approached yet. Moreover, the discovery of Grotefend was in itself so startling, so extraordinary and bold, that no one ventured to follow it up for the next twenty years, when H. Martin found the grammatical flexions of the plural and genitive case. We cannot now specify his further discoveries, or those of Rask, Burnouf, Lassen, Westergaard, Beer, Jacquet, and others who followed; we will only say that they mostly secured for themselves fame and name by rectifying or fixing one or two letters. The last and greatest of investigators of this first alphabet

is Rawlinson, who not only first copied, but also read, the gigantic Behistun inscription—containing more than 1000 lines—of which more anon.

Inscriptions in the Persian cuneiform character are mostly found in three parallel columns, and are then translations of each other in different alphabets and languages, called respectively Persian, Median, and Babylonian; the Achæmenian kings being obliged to make their decrees intelligible to the three principal nations under their sway, as in more recent days the Shah of Persia might have used the Persian, Turkish, and Arabic languages, to make himself understood in Bagdad and Tehran.

The first of the three, the Persian, consists of thirty-nine to forty-four letters, and is the most recent, the most ancient being the Babylonian. It is distinguished by the oblique stroke which divides its words. Its letters are composed of not more than five strokes or wedges placed side by side horizontally or perpendicularly, or both, but never—with one exception—crossing each other. The language is pronounced by all investigators to be as near Zend (q.v.) as possible, and to be the mother-language of modern Persian. It is only twice found by itself; all the other inscriptions are trilingual. The time of its use is confined to the years 570-370 B.C. The oldest instance of its employment is an inscription of Cyrus the Great at Pasargadæ; the most recent, that of Artaxerxes Ochus at Persepolis. The most important is that of Darius Hystaspes, in the great inscription of Behistun (q.v.), which contains, besides genealogical records, a description of the extent of his power, the leading incidents of his reign, prayers to Ormuzd and the angels, and reference to the building of the palaces. Most of these inscriptions occur at Persepolis, Behistun, Naksh-i-Rustam, and Hamadan.

The second kind is called the Median, because it takes the second place in the trilingual inscriptions, under the conquering Persians, but over the conquered Assyrians, and as the Medes stood somewhat in that relation to these two nations, that name was selected. Another name, 'Scythic,' has been proposed, or, by way of compromise, 'Medo-Scythic,' and the language—supposed to have been spoken by those innumerable Tataro-Finnic tribes which occupied the centre of Asia—has been pronounced to be a Turanian dialect. But the process of constructing out of such slender elements as Samojed and Ostiak words, a so-called 'Scythic,' is somewhat similar to the attempt of reconstructing Sanskrit from some detached and very doubtful French and English words. These inscriptions never occur by themselves (one instance again excepted), and being translations of the Persian records, about ninety names have been ascertained, and an alphabet of about one hundred characters—combinations of a syllabic nature—has been established. The principal investigators of this character are Westergaard, De Sauley, Hincks, Norris, and Oppert. Gobineau holds the language to be Huzavaresh, a mixture of Iranian and Semitic.

The third and most important is the Babylonian portion of the cuneiforms. The trilingual records gave the first clue to the deciphering of this character; but many original documents, more than three thousand years older, have since been found in Babylon, Nineveh, and other places near the Euphrates and Tigris, and even in Egypt. On one occasion, the Asiatic Society submitted a cylinder of Tiglath-pileser to four prominent investigators of the subject, and they independently read it nearly alike, with the exception of the proper names, where they widely differed. As a proof of the enormous importance of this character for history, grammar, law, mythology, archæology, and antiquities generally, we name some of the

records which Rawlinson began to publish (now in progress): Babylonian Legends, such as the Fight between Marduk and Tiamat, the Descent of Ishtar into Hades (2000-1500 B.C.); Bricks from Kal'at Sherkât of the early Kings of Assyria (1350-1100 B.C.), in a character much complicated; Annals of Tiglath-pileser I. (1120 B.C.); Annals of Assur-nasir-pal, of Shalmaneser I. and II., Sargon, Sennacherib, Assur-bani-pal, son of Esarhaddon; Inscriptions of Nebuchadnezzar I. and II.; Cylinders containing the name of Belshazzar, &c.; besides syllabaries, vocabularies, mathematical and astronomical tablets, calendars, and a selection from the mythological tablets.

In order to give the reader some idea of the appearance of the cuneiform character, we subjoin the name of Darius, written in the Persian, Scythic, and Babylonian characters.

Babylonian.

The cuneiform signs were originally pictures of objects. It appears that they were first drawn in outline upon some vegetable substance, called in the native documents *ikkhursi*. Whether the supply of this material failed it is impossible to say, but it is quite certain that at a very early period in the history of Babylonia, clay was adopted as a substance for writing upon. On substances like papyrus and leather it is quite easy to draw in outline a picture of any object; but it became more difficult to do this when clay was used, because the outlines of the object represented had to be pressed into it. The necessary result of this was that the shapes of the objects became altered. Thus a circle (1) represented the sun, but when inscribed upon clay it became 2; and a star (3) became 4: in process of time, as scribes became busier, these signs were represented by 5 and 6 respectively.

The use of clay as a writing material completely modified the shape of nearly every character in the cuneiform syllabary. The signs inscribed upon stones of the early empire are most complex, and in many of them it is difficult to see what object they are intended to represent. As time went on, these complex signs became simplified, and wedge after wedge was discarded, until the character was reduced to its simplest form. Lenormant, Hyde Clark, and others adopting their theory, have tried to prove that the Babylonian and Chinese signs are related. In the time of Esarhaddon and Assur-bani-pal, it became the fashion to write inscriptions in the ancient complex character, and special syllabaries of such signs were drawn up. Fragments of these are now in the British Museum. The cuneiform syllabary contains about two thousand signs of a phonetic, syllabic, and ideographic nature. Each sign originally represented an object, but no attention was paid to its ideographic signification when its

syllabic or phonetic value was employed in a word. Before the name of a king, town, city, or private person, &c., a cuneiform sign, being the ideograph for the word following, was placed; after names of places like *Babûlu* (Babylon), a suffix *li*, meaning 'earth' or 'land,' was placed. It is the opinion of some that the cuneiform characters were invented by the primitive Sumerian inhabitants of Chaldæa (who spoke an agglutinative language). See the articles ASSYRIA, BABYLON, WRITING.

Pinches, 1861-80); Grotefend, *Die Keilinschriften aus Behistun* (1854); Lassen u. Westergaard, *Ueber die Keilinschriften* (1845); Hincks, *On the First and Second Kinds of Persepolitan Writing* (Transact. Roy. Ir. Soc. 1846); Norris, *Memoir on the Syriac Version of the Behistun Inscription* (Journal As. Soc. 1853); Rawlinson, *A Commentary on the Cuneiform Inscriptions of Babylon and Assyria* (1850); A. J. Booth, *The Discovery and Decipherment of the Cuneiform Inscriptions* (1902); L. W. King, *Inscriptions of Darius the Great at Behistun* (1907).

**Cune'ne**, a river of Portuguese West Africa, rises on the edge of the interior plateau, and runs 600 miles southward and westward to the sea 60 miles north of Cape Frio. It is nearly useless for navigation, being shallow and barred by sand-banks.

**Cuneo**. See CONI.

**Cunningham**, ALLAN, poet and industrious man of letters, was born at Blackwood, Dumfriesshire, 7th December 1784. His father became factor or land-steward to Miller of Dalswinton, and therefore neighbour to Burns at Ellisland; and Allan, a boy of twelve, followed at the great poet's funeral. At eleven he was apprenticed to a stone-mason, but continued to give all his leisure to poring over native songs and stories. His first publications were his verse and prose contributions to Cromek's sham-antique *Remains of Nithsdale and Galloway Song* (1810). These, while they did not of course deceive the learned, or apparently even Cromek himself, procured the clever young mason the acquaintance of Sir Walter Scott, with whom 'Honest Allan,' as he called him, was always a great favourite. He now removed to London, and became one of the best-known writers for the *London Magazine*, as well as secretary and manager in Chantrey's studio, a post which he held till Chantrey's death in 1841. Though thus busily employed all day, Cunningham maintained an indefatigable literary activity, writing tales, novels, magazine articles, poems, songs, and biographies. His best works were his *Traditional Tales of the English and Scottish Peasantry* (1822); *The Songs of Scotland, Ancient and Modern* (1825); *Lives of the Most Famous British Painters, Sculptors, and Architects* (6 vols. 1829-33); and his edition of Burns, with Life (8 vols. 1834). His *Life of Sir David Walker* appeared posthumously. He died in London, 30th October 1842. Cunningham was a remarkably worthy and kindly man, whose 'stalwart healthy figure and ways' pleased even Carlyle—but then he was from Dumfriesshire. As a Scots poet, he ranks, perhaps, after James Hogg. His songs, although marred by defects in taste, have the true lyrical impulse and movement. See Life by the Rev. David Hogg (Dumf. 1875).

Of his sons, the eldest, Joseph Davey (1812-51), rose in the Indian service, and wrote a good history of the Sikhs (1849); Major-general Sir Alexander (1814-93) wrote on Indian archaeology and statistics; Peter (see below) became a well-known man of letters; Francis (1820-75), also an Indian soldier, edited Marlowe, Massinger, and Ben Jonson.

**Cunningham**, PETER (1816-69), son of Allan Cunningham (q.v.), was born in Pimlico. He was educated at Christ's Hospital, London, entered the

Audit Office in 1834, ultimately became chief clerk, and retired in 1860. He edited a number of the English classics, and wrote various biographical and topographical works, the most important being his *Life of Drummond of Hawthornden* (1833), and his *Handbook of London* (1849).

**Cunningham**, WILLIAM, a distinguished Scottish theologian, was born at Hamilton in 1805, educated at Duns and Edinburgh, and ordained minister at Greenock in 1830. He was called to Trinity College Church, Edinburgh, in 1834, and soon became one of the foremost leaders on the 'Non-intusioneer' side in the great controversy that preceded the Disruption of 1843. He was appointed professor of Theology in the Free Church College in 1843, of Church History in 1845, and its principal on Chalmers's death in 1847. He was moderator of the Free Assembly in 1859, when he received a testimonial amounting to over £7000. He died at Edinburgh, 14th December 1861. His literary executors published *Historic Theology* (1862), *Reformers and Theology of the Reformation* (1862), and *Discussions on Church Principles* (1863). See his Life, by Rainy and Mackenzie (1871).

**Cunningham**, WILLIAM (1849-1919), British economist, was born in Edinburgh, and educated at the university there, and at Trinity College, Cambridge. He took holy orders in 1873, became vicar of Great St Mary's, Cambridge, in 1887, and archdeacon of Ely in 1906. Meanwhile he had been lecturer in history at Cambridge (1884-91), and professor of Economics at King's College, London (1891-97). He wrote much on economic subjects, and did pioneer work in the field of English economic history. His *Growth of English Industry and Commerce during the Early and Middle Ages* (1st ed. 1890), and his *Growth of English Industry and Commerce in Modern Times* (1st ed. 1892), continue standard works.

**Cunninghame-Graham**, ROBERT BONTINE, born 1852, showed his power of vivid observation and caustic criticism in *Moghreb el Akssa*, the record of a journey in Morocco, and in many articles and volumes on South American, Spanish, and Scottish subjects, besides stories. He was associated with Mr Hyndman in the Socialist movement.

**Cunninghamia**, a genus of the Taxodiaceæ family of Coniferae (q.v.), of which the only species (*C. sinensis*) is a lofty evergreen tree of southern China and Cochin China, with sessile leathery leaves, somewhat resembling those of an Araucaria. It is too tender for the climate of Britain, save in peculiarly favourable localities.

**Cuno**, DR WILHELM, president of the Hamburg-Amerika line, became in November 1922, on the resignation of Dr Wirth, chancellor of the German Reich, with a 'bourgeois' coalition cabinet. He resigned in August 1923.

**Cup**, DIVINATION BY, was practised by the ancient Egyptians, and still survives, though with but little credit, in many countries. One of the eastern methods consisted in throwing small pieces of gold or silver leaf into a cup of water, in which were placed precious stones, with certain characters engraved upon them. The infernal powers were then invoked, and returned answer, either in an intelligible voice, or by signs on the surface of the water, or by a representation in the cup of the person inquired about. By a modern method, a fortune is told by observing the sediment in a teacup.

**Cupar**, or CUPAR-FIFE, the county town of Fife, on the Eden, 10 miles W. by S. of St Andrews, 30 NNE. of Edinburgh, and 13 S. of Dundee. In the 12th century a castle of the Macduffs, Earls of Fife, crowned the 'School Hill,' whose northern

slope was afterwards the show-place of mystery-plays and moralities such as the *Thrie Estaitis* (1535) of Sir David Lyndsay (q.v.). Cupar has a handsome United Free Church (1877), the Duncan Institute (1870), and a public park (1871-72). There is a large corn-market. Lord Campbell was a native. The place has been a royal burgh since at latest 1363, and till 1918 it united with St Andrews and five other towns in returning one member to parliament. Pop. 4000.

**Cupellation.** See ASSAYING.

**Cupid** (Lat. *cupido*, 'desire'), also AMOR, the Latin name for the Greek Eros, the god of love. Eros is not mentioned in Homer, but occurs first in Hesiod, whose conception of him is that of a cosmogonic force uniting, as it were, in harmony and love, the conflicting elements of primal chaos. Thus Plato, in his *Symposium*, speaks of him as the oldest of the gods. Quite different, however, from this venerable and somewhat impersonal deity is the Eros of the epigrammatic and erotic poets, the Cupid of Horace and Ovid. The genealogy of this meddling deity is rather confused. He is variously represented as the son of Aphrodite (Venus) by Ares (Mars), Zeus (Jupiter), or Hermes (Mercury). He appears as a wanton boy, playful and mischievous, with bow, arrows, sometimes a torch, quiver, and wings. The eyes are often covered, so that he shoots blindly. His darts could pierce the fish at the bottom of the sea, the birds in the air, and even the gods in Olympus. The immensity of space was his home, but like his mother, he specially loved the flowery thickets of Cyprus. Later poets make a number of Erotes (Amores and Cupidines), with the same attributes as the prototype. We find also an Anteros ('return love'), whose function it is to punish those who do not return the love of others. Thespiæ in Boeotia was the chief seat of the worship of Eros; here was held the Erotidia, a quinquennial festival. Eros or Cupid was a frequent subject for Greek and Roman works of art. The most celebrated statue was that by Praxiteles at Thespiæ.

The beautiful fable of Cupid and Psyche, as given by Apuleius, is a literary version of one of the best-known stories in the world. Of course it is merely an ordinary household tale, with nothing but the names to connect it with the recognised Greek mythology. Here Cupid is merely the invisible bridegroom of scores of stories the world over, with the added name and attributes of the winged son of Aphrodite. See a study of the myth by Andrew Lang, in the introduction to his reprint (1887) of Adlington's translation (1566) of the story as told by Apuleius.

**Cup-markings** on rocks and CUP-MARKED STONES belong to a peculiar class of archaic sculpturings which have attracted much attention among archaeologists. Cup-markings on rocks are chiefly of two varieties—circular cavities or 'cups' pure and simple, and cups surrounded by circles. The circles round the cups are shallow indentations, varying in number up to five or six. Both cups and circles often show the marks of a pointed tool, as if they had been formed by picking, but frequently they appear as if weathered or abraded to a perfectly smooth surface. The cups vary in size from about one inch to three inches or more in diameter. Sometimes they are confluent at the edges, but more usually separate, and occasionally two or more are connected by a shallow groove or duct. They usually occur in groups, sometimes to the number of several hundreds. In such groups the majority are plain cups, intermingled with occasional cups and circles. The circles placed concentrically round the cups are occa-

sionally incomplete at one side, and a radial groove or duct passes from the central cup out through the circles. The circles are only approximately circular, sometimes oval, and occasionally even roughly quadrangular. These groups of cups, mingled with cups and circles, and occasionally with imperfect spirals and other rude and irregular sculpturings, are found on the stones of sepulchral structures of the stone and bronze ages, on rock-surfaces and earth-fast boulders, and on loose stones of small size in the neighbourhood of sites of early habitations or strongholds over nearly all Europe. They are still subjects of superstitious regard in Scandinavia, and while they are found in connection with the megalithic monuments of Europe and India, a resemblance to them has been traced in the conventional symbols of Siva in the modern temples. On the other hand, recent cup-markings (but without the characteristic circles) have been found on the walls of churches in Prussia. A considerable number of examples have come from various parts of America, but few with circles. Many of the smaller cupped stones found there have been attributed to the Indian custom of cracking hickory nuts, by laying them in such cavities and striking them with another stone, while the larger-sized cups and basin-shaped cavities in earth-fast boulders and rocks have been classed as mortars. But the more elaborate sculpturings on rock-surfaces present the central cup, the surrounding circles and the radial groove of the European and Indian examples, and the inference is that they belong to the religious or ceremonial symbolism of primeval man. The most remarkable examples of rock-surfaces sculptured with cups and circles in Scotland are those at Achnabreac in Argyllshire, described by Professor Sir J. Y. Simpson, and at High Banks 'n Kirkcudbrightshire, discovered in 1887 and 1888, and described by George Hamilton in the *Proc. Soc. Ant. Scot.* (vol. xxiii.).

See *Archaic Sculpturings of Cups and Circles, &c.*, by Sir J. Y. Simpson (Edinburgh, 1867); *Incised Markings on Stone, &c.*, from drawings made for the Duke of Northumberland (Lond. 1869); *Skandinaviens Hällristningar* at A. E. Holmberg (Stockholm, 1848); *Observations on Cup-shaped and other Lapidarian Sculptures on the Old World and in America*, by Charles Rau (Washington, 1881); and *Cup-marks as an Archaic Form of Inscription*, by J. H. R. Carriac (1903).

**Cupola** (Ital., from the root of *cup*), a spherical vault, or concave ceiling, on the top of a building; the internal part of a Dome (q.v.). The term is also sometimes used for a dome which is ogival (not hemispherical or semi-elliptical) in outline, or for a small dome. Cupolas are often wholly or partially of glass.

**Cupping** was formerly a popular but is now a little used method of producing local depletion, by the application of partially exhausted *cupping-glasses* to the surface of the skin. By this means the blood is diverted from deeper structures to the surface of an affected part, whence it may be removed by scarifying the skin (wet cupping), or where it may be allowed to remain exuded in the subcutaneous tissues like a Bruise (q.v.), until it be removed by absorption (dry cupping).

Cupping has been a part of surgical practice from the earliest times, and instruments for performing it have been found in use among the least civilised nations. Of old, the cups were either small horns, open at both ends, from which the air was withdrawn by suction at the narrow extremity, or glasses of various shapes, with a small hole in the bottom of each. This hole was plugged with wax, the air exhausted by heat, and when the operator wished to remove them, he withdrew the plug, and allowed the air to enter. The modern cupping-glass is a beaker containing 3 to 6 fluid ounces,

with a finely-ground rim, which adheres closely to the surface of the skin.

The principal improvements have been in the methods of incising the skin. This used to be effected with a common lancet or narrow knife, but now by a 'scarificator,' an instrument consisting of several lancets. A scarificator, glasses, a torch, some spirits of wine, and a lighted candle are placed ready at hand; the part is sponged with hot water, so as to cause an increased flow of blood into it; then dried with a warm towel; the torch, previously saturated with the spirits of wine and lighted, is held for an instant in one of the glasses. By this means the air in the glass is quickly expanded, and when the glass is then rapidly applied to the smooth damp surface of the skin, the rapid rarefaction of its contained air causes it to adhere tightly, and gives rise to determination of blood to the part to which it is applied. When the skin under the glass has become red and swollen, the cupper removes it, applies the scarificator, and as rapidly as possible again exhausts the air from the glass, which he reapplies. The blood will now flow into it; and when enough has been taken, the glass is removed, and some antiseptic lint applied to the wounds. The number of glasses applied depends on the quantity of blood it is thought desirable to abstract; each one will probably withdraw from 3 to 5 ounces. This apparently simple proceeding requires considerable skill, for should the cuts be either too deep or too shallow the blood will not flow. There are many modifications of the ordinary cupping apparatus, but all act on the same principle.

*Dry Cupping* is simply applying the cups as described, without wounding the skin. A hard mass of extravasated blood is found occupying the skin at the site of this operation. The mass, at first cherry-red, becomes in a few days of a dead black colour, then greenish, and finally yellow, following the usual course observed in the healing of a Bruise (q.v.).

**Cupule** (*Cupula*), in Botany, a shortened axis with a number of more or less cohering bracts, numerous and crowded in the acorn, or three in the beech-nut, which more or less completely enclose the ripening fruit. The husk of the hazel-nut may be regarded as an incipient cupule.

**Cupuliferæ** (i.e. 'cupule-bearing'), an old order of dicotyledonous trees and shrubs, more naturally separated into (1) *Betulaceæ* or *Corylaceæ*, the birch and hazel family, including (a) the birch and alder, (b) the hornbeam and hazel; and (2) the *Fagaceæ* or *Cupuliferæ* proper, including (a) the beeches, (b) the chestnuts and oaks. See the articles on these separate trees. Some genera are chalcidogenic.

**Cur**, a name sometimes applied indiscriminately to small dogs of any kind not highly valued, and in this way often particularly appropriated to dogs of mongrel breed, but also used by naturalists as the common designation of many races, of which the Terriers (q.v.) may be considered as the type. See Dog.

**Cura**, CIUDAD DE, or VILLA DE CURA, a town in Venezuela, lies 60 miles SW. of Caracas, to the south of Lake Valencia, has a good deal of industry, extensive cotton plantations, and a pop. of 10,000.

**Curacao** (also spelt *Curacao* and *Curassow*) is the most important of the Dutch West India Islands. It lies about 40 miles from the coast of Venezuela, is 36 miles long by 8 broad, and has a population of 33,000. The capital of Curacao is Willemstad, a very handsome town, situated on the bay of St Anna, with 15,000 inhabitants. The chief produce is salt, and a rock rich in valuable phosphates. The soil of Curacao and its dependent islands is less productive than that of other tropical lands; but careful cultivation pro-

duces sugar, tobacco, maize, figs, cocoa, coconuts, lemons, and oranges. The Curacao orange, *Citrus Aurantium curassaviensis*, is a peculiar variety. Willemstad is the headquarters of the colonial government, which has authority not merely over the neighbouring islands of Aruba and Bonaire, but also over St Eustache, Saba, and the Dutch part of St Martin. Altogether Curacao and its dependent islands have a population of 55,000. The trade is mainly with the United States. Curacao was discovered by Spain in 1527, taken by the Dutch in 1634, conquered by the English in 1807, and restored to Holland in 1815.

**Curacao** is a well-known and esteemed liqueur, usually made in Holland with the dried peel of the Curacao orange, the peel being macerated with water, and then distilled with spirit and water. The result is sweetened with sugar, and a little Jamaica rum is often added. A palatable imitation can be made from the fresh peel of bitter oranges and whisky.

**Curari**, URARI, WOORALI, or WOORARA, is a celebrated poison used by some tribes of South American Indians for poisoning their arrows. It is by means of this poison that the small arrows shot from the Blowpipe (q.v.) become so deadly. It is brought to Europe as a black, brittle extract, resinous in appearance, and encrusting the sides of little gourds containing it. The source of this deadly poison was for long unknown, owing to the natives jealously guarding the secret. The process of manufacture has now, however, been witnessed and described by several travellers, and in each case some species or other of *Strychnos* has been recognised as the source of the poison. There seem to be four distinct varieties of curari, each characteristic of a different tract of country, and probably varying in their physiological action; but for our purpose we may confine ourselves to that kind which is used in physiological experiments. Curari is one of those poisons which, being difficult to absorb, have little action when taken into the stomach, but when introduced into a wound act with great promptness. The symptoms caused are loss of muscular power, feeble respiration, and death by suffocation. By means of artificial respiration it is possible to sustain life for a lengthened period, although the animal is apparently insensible to pain. The heart usually keeps beating after the cessation of breathing, and only after very large doses of the poison does the arterial pressure fall.

At first it was supposed that curari contained strychnine, but as its action was so entirely different, this view was soon abandoned. Prolonged research separated a special alkaloid, *Curarine*, which possesses the leading properties of the poison itself. It forms salts, and is said to be twenty times as strong as curari. There is also another alkaloid, *Curine*, present in curari, which is not so powerful or poisonous as Curarine. In medicine curari is very little used. It has been proposed to employ it in lockjaw, hydrophobia, and as an antidote in poisoning by strychnia; but although it quiets the spasm, it has no direct curative effect, and it may cause an equally fatal paralysis.

Besides curari proper, there are two other arrow-poisons called Corroval and Vao. These, which are brought from New Granada, have an entirely different action on the body, as they primarily stop the beating of the heart, whereas with curari the heart continues to beat after breathing has ceased.

**Curassow**, or HOCO (*Craw*), a genus of large game-birds inhabiting the forests of Central and South America. Their most distinctive features concern the head. This is adorned with a crest

of feathers, curled forwards, and capable of being raised and depressed; while the often brightly coloured cere is enlarged into a prominence at the root of the high beak. Eight species are found from Mexico to Paraguay, predominantly arboreal, living mostly on fruits, but in general habit like poultry. They are very unsuspicious of danger, especially careless at the love-making season, and are very readily tamed. The best-known species is *C. alector*—the Royal Pheasant of the Mexicans.

Crested Curassow.

It is a very sombre bird, about the size of a turkey. It is occasionally domesticated, and a stock imported into Holland at the end of last century seemed to become acclimatised. It was, however, lost amidst the troubles subsequent to the French Revolution. Though their love-making is keen, the birds are not very productive, and it is probable that the natives have discovered that this apparently very profitable bird will not breed readily under domestication. Closely allied, and of similar distribution and habit, are the fierce Guans and Penelopes (*Penelopinae*), and the rare Mountain Curassow (*Oreophaps derbianus*). The Turkeys (q.v.) are also near relatives.

**Curate**, literally one who has the cure (Lat. *cura*, 'care') of souls, in which sense it is used in the Church of England Prayer-book, 'all bishops and curates'; as the cognate word *curé* is used in French to denote the incumbent of a parish. It is, however, generally used now to denote the unbeneficed parochial clergy in the Church of England, more exactly styled 'assistant curates.' Formerly, such curates were usually the deputies of non-resident incumbents, but now they are mostly helpers of resident pastors. A curate, in this sense, is a minister employed by the incumbent of a church (rector or vicar), either as assistant to him in the same church, or else in a chapel of ease within the parish belonging to the mother-church. He must be licensed and admitted by the bishop of the diocese, or by an ordinary having episcopal jurisdiction, who also usually appoints his salary. Any curate that has no fixed estate in his curacy, not being instituted and inducted, is liable to removal on six months' notice from the incumbent, and to summary withdrawal of his license by the bishop. In the latter case, an appeal to the archbishop of the province is open. But there are *perpetual* curates as well as temporary, who are appointed where tithes are inappropriate and no vicarage was ever endowed: these are incumbents, and not removable, and in new district parishes their title is now vicar.

**Curator**, a term taken over from Roman law into Scots law for the guardian of minors, lunatics,

&c. See **GUARDIAN, INFANT, PARENT AND CHILD, TUTOR**; and for *Curator Bonis*, **INSANITY**.

**Curb**. See **BRIDLE**.—The lesion known as 'curb' in the horse is a bulging enlargement, a deviation backwards, opposite the lower part of the hock, of the straight line which normally runs from the point of the hock to the fetlock. It is usually due to sprain of the calcaneo-cuboid ligament, is not uncommon in short and in sickle hocks, and is sometimes hereditary. It is mostly confined to light-bred horses and to young animals. It is seldom met with in a horse that has reached maturity—except as the result of more than ordinary violence. There is often lameness at first, and if it be inflamed and painful a high-heeled shoe may be beneficial, with hot fomentations and an anodyne cooling lotion. As a rule in the course of a week the ordinary shoe may be adjusted, and the curb may require a blister. But for a permanent cure, and to enable an animal to stand hard work, there is nothing to equal the hot iron, which may be only lightly applied. A large curb may not disappear altogether, but after it has been treated and the inflammation has subsided, it seldom causes lameness, but is always a blemish.

**Curcas**. See **PHYSIO NUT**.

**Curculio**. See **WEEVIL**.

**Curcuma** (Arab. *kurkum*) an Indian genus of Zingiberaceæ, the ginger and cardamom order. *C. longa* is widely cultivated in Southern Asia, its rhizomes (*radix curcumæ longæ* of pharmacists) being the source of Turmeric (q.v.). Young plants also yield a kind of arrowroot, but this is especially prepared from *C. leucorrhiza*, with colourless rhizomes. *C. zedoaria* yields a tonic medicine (*radix zedoariæ officinalis* or zedoary of pharmacists), and is also used as food. *C. amada* is the mango ginger of Bengal.

**Curé**, the name applied in France to a priest with a cure of souls, properly the priest of a regular parochial as opposed to a succursal church, but commonly applied to any pastor with spiritual functions.

**Cures**, an ancient town of the Sabines, 25 miles NE. of Rome, whence the Romans, after the people of Cures united with them, came to be called *Quirites*. See **ROME**.

**Cureton**, **WILLIAM**, Syriac scholar, born at Westbury, Shropshire, in 1808, studied at Oxford, and was ordained in 1831. In 1837 he entered the British Museum as assistant-keeper of manuscripts, and here his labours brought to light a Syriac version of the Epistles of Ignatius (q.v.), remains of a Syriac recension of the Gospels, and other MSS. of more or less value, which involved their editor in long controversies. In 1849 Cureton was appointed canon of Westminster and rector of St Margaret's. Among other honours, he received the degree of LL.D. from Oxford and of D.D. from Halle, and was a Fellow of the Royal Society and a foreign associate of the Institute of France. He died 17th June 1864.

**Curfew** (Fr. *couvre-feu*, 'cover fire'). To William the Conqueror is ascribed the introduction of the curfew-bell into England, the object of which was to warn the people to cover up their fires, and retire to rest. The time for ringing these bells was sunset in summer, and about eight o'clock in winter; and certain penalties were imposed upon those who did not attend to the signal. The practice of ringing the curfew-bell, however, appears to have prevailed throughout Europe long before the era of the Norman Conquest, its object being the prevention of fires, which, owing to houses being chiefly composed of wood, were then both frequent and destructive.

against four, with a director styled *skip* for each; after which a certain length of ice is chosen on which to play. This is called the *rink*. Certain marks are then made at each end of the rink, consisting of several concentric rings, called *brougs*, and a centre, called the *tee*. The game is decided by time, or by one party first attaining a certain number of shots, such as 21 or 31; and the keenness displayed by rival sides in competing for victory is perhaps without a parallel in any other pastime whatever. One on each side plays alternately. The chief object of the player is to hurl his stone along the ice towards the tee, with proper strength and precision; and on the skill displayed by the players in placing their own stones in favourable positions or in driving rival stones out of favourable positions, depends nearly all the interest of the game. At a certain distance from each of the tees, a line—the *hog-score*—is drawn across the ice; and any stone not driven beyond this mark counts nothing, and is laid aside. In country places, a dinner composed of 'beef and greens,' the well-known curler's fare, generally concludes the day's diversion, which, taking place when outdoor labour is suspended, is felt to be no encroachment on rural occupations. Since 1902-3 Scottish teams have played many matches in Canada.

For laws of curling and general remarks, see *The Channel-stane* (four series, 1883-84, the last with ample bibliography); *Descriptive and Historical Sketch of Curling* (1828), reprinted as *The Kilmarnock Treatise* (1883); *Curling, Ye Glorious Pastime* (1882), a reprint of the *Account of the Game of Curling* (1811); Dr James Taylor, *Curling* (1884); Rev. J. Kerr, *History of Curling* (1888); J. G. Grant, *The Complete Curler* (1914); and the annuals of the Royal Caledonian Curling Club from 1839.

**Curll**, EDMUND (1675-1747), a notorious London bookseller of the first half of the 18th century. His connection with *Court Poems* (1716) led to his first quarrel with Pope, who afterwards made the bookseller figure in the *Dunciad*. He earned an unenviable reputation for the publication of indecent literature, which afterwards received the brand of Curlicism. He was twice (1716 and 1721) at the bar of the House of Lords for publishing matter regarding its members; was tried and convicted for publishing obscene books (1725), fined (1728) for the issue of *Nun in Her Smock* and *De Usu Flagrorum*, and spent an hour in the pillory for his *Memoirs of John Ker of Kersland*. His announcement of *Mr Pope's Literary Correspondence* (1735) led to the seizure of the stock, and furnished Pope (who has been proved to have instigated its publication) with a sufficient excuse for the issue of an authentic edition (1737-41). Curll did not deal solely in garbage, as is shown in a list of his containing 167 standard works, including Swift's *Meditation on a Broomstick* (1710), Dr South's works, &c. His *Curliad* (1729) is styled a 'hypercritic upon the Dunciad Variorum.' It was of Curll's biographies that Arbuthnot wittily said they had added a new terror to death.

**Currach**. See CORACLE.

**Curragh**, a large undulating down in the centre of County Kildare in Ireland, 2 miles E. of Kildare town. It is the property of the crown, and in it is a large camp of exercise, established in 1855, with accommodation for 12,000 troops (see CAMP). The Curragh of Kildare is even better known as a famous racecourse.

**Curran**, JOHN PHILPOT, Irish orator, was born at Newmarket in County Cork, son of the seneschal of the Manor Court there, July 24, 1750. At Trinity College, Dublin, he was as idle and reckless as he had been at school, but spite of his dissipations he contrived to learn something of law, and the boisterous taproom debates of his life in Dublin

and London shaped him into an orator. After two years at the Middle Temple, London, he was called to the Irish bar in 1775. Here his conviviality, his wit, and his vehement eloquence, soon made him a prominent figure, and led to his being employed in many of the greatest causes of the time. In 1782 he became King's Counsel, and next year was returned to the Irish parliament for Kilbeggan. He became a strong supporter of Grattan, but his eloquence proved less effective on the floor of the House than before an Irish jury. His sarcastic retorts led him into several duels, of which, in the course of his career, he fought no less than five, all fortunately without serious harm. Although a staunch Protestant like so many great Irish patriots, Curran had a warm sympathy with his suffering Catholic countrymen, and was eloquent and constant in his unavailing appeals to the government to change a policy which was driving the Irish into rebellion. With his defence of Archibald Hamilton Rowan in August 1792 commenced the long series of defences in state-trials which have shed such a lustre on his name. The insurrection at length broke out in 1798, but was speedily suppressed, whereupon the prosecutions of its leaders at once began. Curran flung himself into their defence with a heroic energy that rose above the brow-beatings of the bench and insured him an immortality of affection in the hearts of his fellow-countrymen. The last of his defences was that of Napper Tandy in May 1800. Then came the Union, which Curran had always opposed as 'the annihilation of Ireland.' His own health was now shattered, and soon domestic troubles followed to darken his later years. His wife eloped with a clergyman, and his youngest daughter, Sarah, pined away and died in Sicily, a few months after the hapless fate of her bright young lover, Robert Emmett (1803). Her story is immortalised in Moore's well-known lines, 'She is far from the land where her young hero sleeps.' After the death of Pitt (1806) and the accession to power of the Whigs, Curran was appointed Master of the Rolls in Ireland, an office which he held till his retirement in 1814. He died in London, 14th October 1817. His remains were re-interred in Glasnevin Cemetery, Dublin, in 1834. Curran's little figure, ugly face, bright black eyes, and intense vivacity, formed a sufficiently unique personality; but his brilliant wit, his quickness in repartee, and the felicity of his ready language were unparalleled. MacDonagh puts an unpleasant complexion on his servility to the government, and in his relation to his daughter calls him 'an inhuman scoundrel.'

See his *Speeches*, edited, with a Life, by Thomas Davis in 1855; *Lives* by his son, W. H. Curran (1819), A. Stephens (1817), and O'Regan (1817); Ch. Phillips, *Curran and his Contemporaries* (1850); and MacDonagh, *The Viceroys Postbag* (1904).

**Currant**, a name originally belonging to a small kind of grape (see CURRANTS), and transferred, in consequence of the similar size of the fruit, to many species of Ribes (order Saxifragaceæ, sub-order Grossulariaceæ). The species known as *currants* are destitute of spines, and have the flowers in racemes: the spiny species are known by the name Gooseberry (q.v.). Among the fruit-shrubs most generally cultivated in our gardens is the Red Currant (*R. rubrum*), *Groseille* of the French, a native of woods and thickets in the south of Europe, found also in some parts of Asia and of North America, perhaps rather a naturalised than a truly native plant in Britain. It has long been cultivated, although it does not appear that it had a place in the gardens of the ancient Greeks or Romans. The berries, besides being used for dessert, and to a much greater extent for pies, and for making jelly (eaten with mutton and hare), are used

also for making an agreeable and refreshing beverage, called in France *Eau de Groseilles* (made of the juice of the fruit, water and sugar, strained and iced), and a well-known fermented liquor called *Currant Wine* (q.v.).—The White Currant is a mere variety of the red, the result of cultivation, with fruit less acid, and more fit for

Red Currant.

dessert, generally also rather larger. There are many sub-varieties, and many intermediate shades of colour. Both the red and the white currants are either trained as standard bushes, or against walls, the latter treatment producing larger and finer fruit, and both are sometimes trained on a north wall, to retard their ripening till after the ordinary season. They grow readily, like the shrubs of this genus in general, from cuttings. Unlike the black currant, the red and the white grow in clustered bunches.—The Black Currant (*R. nigrum*), *Cassis* of the French, grows in moist woods, and on the banks of streams in Europe and the north of Asia. The fruit is much larger than the red currant, and cultivation has lately produced varieties remarkable for size.

There is a variety found in Russia with yellow berries. The jelly and preserve made from it are very useful for sore throats, as is also *black currant vinegar*, made in the same manner as raspberry vinegar. In Russia, the berries are gathered in large quantities in the woods, and dried in ovens, to be used in pies. They are tonic, and also slightly diuretic and sudorific. A liqueur, called *Liqueur de Cassis*, is prepared in France from the black currant. Those who are fond of the flavour of green tea may gratify their taste by dropping one or two black currant leaves or buds into the teapot during infusion. The 'big bud disease' is caused by the black currant gall-mite (*Eriophyes ribis*), and is only mitigated by soap and sulphur-spray; affected bushes should simply be burnt.—Many other species, some of them probably deserving of cultivation, are found in temperate and cold climates in almost all parts of the world. One with large beautiful red berries, occurs on the Himalaya at an elevation of 13,000 feet.—*R. oxyacanthoides*, a native of North America, is much like the common gooseberry in flavour, and the colour is red or green in different varieties.—*R. lacustre*, also a North American species, produces its fruit in bunches, a fruit like that of the black currant.—The fruit of *R. fragrans* is sweet, but the species is more remarkable for the production of a pleasant balsamic resin which exudes from the under side of the leaves in yellow drops and has the smell of black currants.—The Red-flowered Currant (*R. sanguineum*), now so common as an ornamental bush in shrubberies, and trained on walls, producing in April a profusion of deep-red flowers in large drooping racemes,

is a native of the north-west of America, and was introduced into Britain in 1826. Its bluish-black, mucilaginous, insipid berries are not, as is popularly believed, poisonous.—The Golden Currant (*R. aureum*), also a very ornamental shrub, from the same regions, has a tubular calyx and long golden-yellow flowers. Its fruit, which is either yellow or black, and of fine flavour, is not freely produced in Britain.—The name Native Currant, or Australian Currant, is given in Australia to the berries of different shrubs, particularly the white berries of *Leucopogon Richii* (order Epacridaceæ). Other fruits bearing the same name are produced by species of *Coprosma* (order Rubiaceæ), but they are very inferior.

**Currant**, a small kind of raisin, is the dried red or blue berry of a small-fruited seedless variety of the common vine, which is cultivated in the East, and especially the Ionian Islands and in Greece. The name, originally *Raisin de Corinthe*, is derived from the city of Corinth, in the neighbourhood of which currants were first cultivated. They are very small, round, with a thin skin, without seeds, and very sweet. Those brought from the island of Zante are most esteemed. The grafting, pruning, trimming, and irrigating of the vine-stocks, which of late have suffered from the phylloxera, involve much labour. As the grapes ripen, the bunches are dusted with sulphur, to keep off the dreaded *Oidium* (q.v.); rain at this period always injures and sometimes ruins the crop. The vintage is in August. The currants when ripe are spread out on drying-grounds in layers half an inch thick, and frequently turned. The currants, now loosened from the grape-stick, are tightly packed in barrels for exportation, and are an important Greek export. In a few districts of Greece, a very sweet wine is made from currants.

**Currant Gall**, an oak-gall resembling a currant, due to *Spathogaster baccarum*. See GALL-FLY.

**Currant Moth**, or MAGPIE MOTH (*Abraaxas grossulariata*). See GOOSEBERRY CATERPILLAR.

**Currant Wine** is made of the juice of red or white currants, to which is added about one pint of water for every four pints of berries employed. About a pound and a half of sugar is afterwards added to each pint of the liquor, a little spirits being generally also added, before it is set aside to ferment. A larger quantity of sugar is sometimes employed, and no water, and a stronger and sweeter currant wine is thus produced. Fermentation requires several weeks, and the wine is not fit for use for at least some months afterwards. Black currant wine is made in the same way from black currants, but the fruit is put on the fire in as small a quantity of water as possible, and heated to the boiling-point before it is bruised.

**Currency** means originally the capacity of being current, or, as Johnson defines it, 'the power of passing from hand to hand.' It is applied in practice to the thing that is so current, and generally to whatever, by being current among any nation or class of persons, serves as the money with which they buy commodities or pay their debts. It is necessary to be content with a practical explanation, without venturing on a scientific definition of the term, because, among the many disputed points in political economy, there is none productive of more exciting controversy than the proper regulation of the currency; and the advocate of each theory is apt to define the term according to the view he takes of the functions of government regarding currency. Whether correctly or not, it is applied in practice to everything that is received for payment. It differs from the word money, in its popular acceptance, in as far as it includes various

substitutes for the metallic money of a country, especially bank-notes. The leading question among political economists regarding currency is, how far it should be restrained. The most effectual method of restraining it is by confining it to the precious metals. If it were law that none but a gold currency should be used in any country, and if, at the same time, there were no effort to tamper with this gold currency, and give it an artificial value, the currency of that country would always be adjusted to the general level of prices throughout the commercial world, and if it were redundant would be at once exported, and if deficient at once imported in exchange for commodities.

A country which does not produce gold must pay for its gold with commodities, and consequently it is a very expensive currency, and therefore, ever since man's ingenuity was turned to trade, methods have been devised for superseding gold or the other precious metals by something cheaper. Unless, however, law or custom intervenes to give it efficiency, this cheaper material will only be worth its own (so-called) intrinsic value. A five-pound Bank of England note is worth so little in its intrinsic value as a picture upon thin paper, that such a value can hardly be expressed. It derives its power as currency from the obligation it fixes on a great rich corporation to make good its professed amount to the holder. We thus pass from a purely bullion currency to the next step of restraint, which is generally called a mixed currency. Here some maintain that no note should be issued unless the banker or other person issuing it has in his possession as much bullion as will pay it. Others say it is sufficient that he is bound to pay its amount in bullion on demand without his actually possessing the bullion throughout the whole period of the currency of the note. A third party, again, are for a currency entirely free of a metallic basis; they hold that naturally paper money, passing from hand to hand, will represent transactions, and will therefore come in the end to be made good in some shape or other; and they further hold, that if some losses should thus occur, these will be more than compensated by the rapid increase of trade and enterprise, caused by a free trade in currency, as it is termed—that is to say, by every man issuing his own notes or promises to pay to whoever will take them. As a matter of fact, every nation beyond the first stage of civilisation has always regulated its currency, and Adam Smith carefully points out that this is no real infringement of natural liberty and free trade. Through a succession of practical measures, reached with considerable caution, the English have come to a mixed currency, resting on a compromise between the two classes of mixed currency above referred to. In the theory of the measures brought to completion under Sir Robert Peel in 1844, it is admitted that, to a certain extent, a currency can be based on transactions and the property of those concerned in them, but that a limit must be drawn, to prevent the power of creating such a currency from running to excess, by the issue of notes which cannot be immediately made good by those who issue them. Accordingly, the several banks in existence were allowed to continue their note circulation, but they were permitted to increase it only on the condition of having bullion in their coffers to pay the additional notes issued by them.

A currency which is not worth its nominal value in bullion is called a 'depreciated currency.' After 1914, owing to the excessive issue of paper money, the currency of all belligerent countries greatly depreciated. By the end of 1919 the British paper pound had depreciated 21 per cent., the French paper franc 66 per cent., the Italian paper lira

69 per cent. The Russian currency, and subsequently the German mark, have equalled the French revolutionary 'assignats' in becoming practically worthless. A depreciated currency may be created by a government calling notes or any other form of money a legal standard, and issuing a greater quantity of it than the real transactions of the country and the property passing from hand to hand require; or it may be created by private persons acting under laws by which the right of issuing a currency is not duly limited. This faculty which a currency has of becoming depreciated without being repudiated, is the real source of danger in all proposals for an unfettered currency, or a free trade in the issue of money. If the bank-notes for which bullion cannot be immediately obtained were repudiated, there might be a natural check on over-issues; but it is their nature, on account of the difficulty of getting bullion for them, or the chance that it may never be got, that they pass at a discount or reduction of their value. Hence such a currency would be ever shifting; there would be no permanent standard, and the person incurring a debt before a depreciation which he pays afterwards would, in reality, be paying his creditor a dividend only. A 'token' currency, the material of which is avowedly overvalued, and which is issued in limited quantities for use in small payments, must be distinguished from a depreciated currency. In the silver currency of Britain, before the war period, a pound was worth little more than four-fifths of a sovereign, even at the old valuation of silver, at about 60d. per oz. If a person due £100 could pay it in silver, he would get off with a dividend of from 16s. to 18s. in the pound; but by law, silver is not a legal tender for more than 40s. The copper currency is so far below its real value that it has not been thought worth while to give it a permanent weight—the pence and halfpence now issued are little more than half the weight of those of former mintages; but they are only a medium for small sums, and the royal stamp establishes reliance. See **BANKING, BIMETALLISM, BULLION, MONEY**; *Hawtrey's Currency and Credit* (1919); and *Reports of the Commission on Currency* (1918 and 1919).

**Currents.** See ATLANTIC, PACIFIC, &c., GULF STREAM, SEA.

**Currie, JAMES**, the earliest editor of Burns, was born at Kirkpatrick Fleming manse, in Dumfriesshire, 31st May 1756. He spent five years at Cabin Point, Virginia, in a mercantile situation (1771–76), then studied medicine at Edinburgh and Glasgow; and settling in Liverpool in 1780, soon obtained a good practice. His chief medical work was the able *Reports on the Effects of Water in Febrile Disease* (1797); but he is best remembered by his edition of Burns (1800; 7th ed. 1813), with a life and criticism of the poet's writings, which he undertook solely for the benefit of Burns's family, and which was long the basis of all subsequent editions. Dr Currie died at Sidmouth, 31st August 1805. See the Life by his son (2 vols. 1831).

**Currying.** See LEATHER.

**Curry Powder**, or CURRY PASTE, is a compound of turmeric, coriander, pepper, ginger, and various spices; it is used to a large extent in India and elsewhere as a seasoning for a variety of dishes.

**Curse of Scotland**, a term popularly applied to the *nine of diamonds* in a pack of playing-cards. Perhaps the least worthless of the many explanations offered is that it involves a reference to the detestation entertained in Scotland towards John Dalrymple, first Earl of Stair, on account of his activity in promoting the Union, and especially for his share in the Massacre of Glencoe. His heraldic

bearings, 'or, on a saltire azure, nine lozenges of the field,' bore a fanciful resemblance to the nine of diamonds.

**Cursing.** See SWEARING.

**Cursitor**, an old name for clerks of the Court of Chancery who made out writs. The *Cursitor Baron* used to administer oaths to sheriffs, bailiffs, &c.

**Curtain**, in Fortification, is the portion of rampart connecting one Bastion (q.v.) with another.

**Curtesy.** See COURTESY; HUSBAND AND WIFE.

**Curtis**, GEORGE WILLIAM, American author, born in Providence, Rhode Island, in 1824; in 1850 joined the staff of the New York *Tribune*, and was one of the editors of *Putnam's Monthly* from 1852 to 1869. He commenced the 'Editor's Easy Chair' papers in *Harper's Monthly* in 1853, and became principal leader-writer for *Harper's Weekly* on its establishment in 1857. A novel, *Trumps* (1862), and most of his books appeared first in these journals. Until 1884 he was a Republican; then he supported Cleveland. He died at New York, 31st August 1892. See Life by E. Cary (1894).

**Curtius**, ERNST, a distinguished German classical archæologist and historian, born September 2, 1814, at Lubeck. He studied philology at Bonn, Göttingen, and Berlin, visited Athens with Brandis in 1837, and next accompanied his teacher, Otfried Müller, in his travels through Greece. For some time he taught in two Berlin gymnasiums, next became extraordinary professor at the university there, and (1844-49) tutor to the Crown Prince of Prussia. In 1856 he succeeded Heimann as professor at Göttingen, whence he was recalled in 1868 to become ordinary professor at Berlin. Since 1853 a member of the Royal Academy of Sciences, he was in 1871-93 one of its permanent secretaries. His earlier works were *Klassische Studien* (1840), *Anecdota Delphica* (1843), *Inscriptiones Atticæ Duodecim* (1843), and *Die Akropolis von Athen* (1844). The fruits of his repeated visits to Greece and Asia Minor—last in the spring of 1874, to make preparations for the intended excavations at Olympia at the instance of the German government—appear partly in the memoirs of the Göttingen Society of Sciences and of the Berlin Academy, and partly in his books, *Naxos* (1846), *Olympia* (1852), *die Ioniæ* (1855), *Die Topographie Kleinasiens* (1872), and *Ephesos* (1874). His orations, delivered at Göttingen in the capacity of 'Professor Eloquentiæ,' were collected in 1864; those at Berlin, under the title, *Altertum und Gegenwart* (2 vols. 1875-82). Besides these and numerous papers in the special archæological and philological journals, Curtius published *Peloponnesos* (2 vols. 1851-52), a luminous description of that part of Greece, and *Griechische Geschichte* (3 vols. 1857-61; 6th ed. 1887-89; trans. by A. W. Ward, 1868-76), a work unequalled for its insight into the artistic growth and development of the Greek race. With Kaupert he prepared the *Atlas von Athen* (1878); earlier, with Adler and Hirschfeld, *Die Ausgrabungen zu Olympia*, the official account of the excavations at Olympia (3 vols. 1877-78). He died 11th July 1896.

**Curtius**, GEORG, a distinguished classical scholar, the brother of the preceding, was born at Lubeck, April 16, 1820, and studied at Bonn and Berlin. After teaching some time at Dresden and Berlin, he became in 1849 extraordinary, in 1851 ordinary, professor of Classical Philology at Prague, and settled as such at Kiel in 1854, at Leipzig in 1862. He died August 12, 1885. One of the soundest Greek scholars in Germany, Curtius was the first philologist of the generation that succeeded the giants Bopp and Benfey. His most important

works were *Griechische Schulgrammatik* (1852; 20th ed. 1890), translated into many languages (into English in Dr Smith's series in 1863); next the *Erläuterungen* to the foregoing (1863; 3d ed. 1875), translated into English by Abbott in 1870; *Grundzüge der Griechischen Etymologie* (1858; 5th ed., with the collaboration of A. Windisch, 1879), translated into English by A. S. Wilkins and E. B. England, 1875-76; and *Das Verbum der Griechischen Sprache* (1873-76; 2d ed. 1877-80), translated by Wilkins and England, 1880. Other works were *De Nominum Græcorum Formatione* (1842), *Die Sprachvergleichung in ihrem Verhältniss zur Klassischen Philologie* (1845), *Sprachvergleichende Beiträge zur Griechischen und Lateinischen Grammatik* (1846), *Philologie und Sprachwissenschaft* (1862), *Zur Chronologie der Indogermanischen Sprachforschung* (1867; 2d ed. 1873), and *Zur Kritik der neuesten Sprachforschung* (1885), his last work, in which he vigorously assails the theories of the 'new grammarians,' and to explain the word-changes in a language maintains the necessity of a third principle of varying or sporadic change, in addition to invariable phonetic law and the operation of analogy. In the famous *Studien zur Griech. und Lat. Grammatik* (10 vols. Leip. 1868-77) Curtius united his own papers with those of his pupils and others, including Brugmann, Fick, G. Meyer, and Windisch. The ninth volume contained Brugmann's famous paper on the 'nasalis sonans,' which first marked the revolt of the 'neogrammatici' against the master and traditional philology. Curtius founded in 1878, with L. Lange, O. Ribbeck, and H. Lipsius, the *Leipziger Studien zur Klassischen Philologie*.

**Curtius**, METTUS or METTIUS, a noble Roman youth who heroically sacrificed his life for the welfare of his country, 362 B.C. A yawning chasm had opened in the forum, and the soothsayers declared it could only be filled by throwing into it the most precious treasure of Rome; whereupon Curtius appeared on horseback in full armour, and exclaiming: 'Rome has no greater riches than courage and arms,' leaped into the abyss, which at once closed over him.

**Curtius**, QUINTUS (Quintus Curtius Rufus), author of the work *De Rebus Gestis Alexandri Magni*, in ten books, of which the first two have been lost, and the text of the remainder has come down to us in an imperfect condition. Some critics have placed him in the reign of Augustus against the evidence of his style, which is moulded on that of Seneca, and would naturally suggest a writer contemporary with Claudius and Nero; others, as Niebuhr, under Severus; and others again much later. Curtius was poorly equipped as a historian, and his book has but little value as history; but its style, if mannered and declamatory, is elegant and pleasing. The *editio princeps* was published at Venice about 1471. Modern editions are those of Müttzell (1841), Zumpt (1849), and Vogel (1875-80).

**Curule Chair** (*sella curulis*), the chair of honour of the old Roman kings, and later of consuls, prætors, 'curule ædiles,' and some of the other higher magistrates of the republic having senatorial rank. It was a folding-stool originally of ivory, then of metal, with curved legs crossing.

**Curvature.** For Curvature of Strata, see ANTICLINE, GEOLOGY, MOUNTAINS; for Curvature of Spine, see SPINE.

**Curve**, a line described by a point moving so that the direction changes at every instant; and in mathematics the term curvature is restricted to lines that follow some law in their change of direction. Thus, the law of the circle is, that all points of it are equally distant from a fixed point, called the centre. The law of a plane curve is generally

expressed by an equation between the co-ordinates of any point in it referred to a fixed point; and thus the doctrine of curves becomes matter of algebra (see CO-ORDINATES). When the equation of a curve contains only powers of  $x$  and  $y$ , the curve is algebraic; when the equation contains other functions, logarithms for instance, of  $x$  and  $y$ , the curve is called transcendental. The cycloid, e.g., is a transcendental curve.

There are also curves, like some spirals, that do not continue in one plane; these are called curves of double curvature, and require, in analysis, three co-ordinates and two equations.—Curves are said to be of the first, second, third, &c. order, according as their equations involve the first, second, third powers of  $x$  or  $y$ . The circle, ellipse, parabola, and hyperbola are of the second order of curves. There is only one line of the first order—viz. the straight line, which is also reckoned among the curves.—The higher geometry investigates the amount of curvature of curves, their length, the surface they inclose, their tangents, normals, asymptotes, evolutes and involutes, &c.

The number of curves that might be drawn is of course infinite. A large number have received names, and are objects of great interest to the mathematician; see CONE, CIRCLE, ELLIPSE, PARABOLA, HYPERBOLA, CUSPID, CONCHOID, CYCLOID, CATENARY, EVOLUTE.

**Curwen, JOHN** (1816–80), the apostle of the Tonic Sol-fa System, was born at Heckmondwike. In 1843 his *Grammar of Vocal Music* appeared, and in 1864, to push his system, he resigned his charge as Independent minister at Plaistow. See Memorials by his son (1882).

**Curzola** (Croatian *Korčula*), a Dalmatian island, 25 miles long; pop. 20,000 (7000 in the town of Curzola).

**Curzon, GEORGE NATHANIEL**, Marquis Curzon of Kedleston (1859–1925), son of Lord Scarsdale, was educated at Eton and Oxford. He was private secretary to the Marquis of Salisbury (1885), Under-secretary for India (1891–92), and for Foreign Affairs (1895–98). In 1898 as Viceroy of India, with an Irish peerage, he undertook important administrative changes (including the partition of Bengal). During his second term of office he resigned (1905), disapproving the co-ordinate authority given to the Commander-in-chief. In 1911 he was made an earl of the United Kingdom, in 1921 a marquis. He was Lord Privy Seal (1915), Lord President (1916 and 1924–25), and Foreign Secretary (1919) in Coalition and Conservative Governments. He wrote on Russia in Asia (1889), Persia (1892), the Far East (1894), university reform (1909); also *War Poems* (1915) and *Tales of Travel* (1923); *British Government in India* (1925).

**Cusa, NICOLAUS OF** (1401–64), born at Cusa on Kues on the Moselle, studied at Deventer with the Brothers of the Common Life and at Padua. As archdeacon of Liège he took the anti-papal side at the Council of Basel, but was ultimately Bishop of Bixen in Tyrol, cardinal, and papal legate to Constantinople. He exposed the false Isidorian decretals, denounced perverted scholasticism in *De Docta Ignorantia*, taught that the earth went round the sun, and in pantheistic tendencies and otherwise was a precursor of Giordano Bruno.

**Cuscus**, a marsupial akin to the Phalanger (q.v.).

**Cushing, CALEB**, American statesman, born in Salisbury, Massachusetts, in 1800, was admitted to the bar in 1821, sat in the state legislature and senate, and was elected to congress in 1835–43. He arranged the first treaty between China and the United States in 1844; raised and commanded a regiment in the war with Mexico; and was United

States attorney-general in 1853–57, counsel for the United States at the Geneva Conference in 1872, and minister to Spain in 1874–77. He died in 1879.

**Cushman, CHARLOTTE SAUNDERS**, a distinguished American actress, born in Boston in 1816, appeared first in opera in 1834, and as Lady Macbeth in 1835. Miss Cushman played sometimes in high comedy, but her name is identified with tragic parts. In 1844 she accompanied Macready on a tour through the northern states, and afterwards appeared in London, where she was well received in a range of characters that included Lady Macbeth, Rosalind, Meg Merrilees, and Romeo—her sister Susan (1822–59) playing Juliet. Miss Cushman retired from the stage in 1875, and died in Boston, 18th February 1876.

**Cusk.** See TORSK.

**Cusp** (Lat. *cusps*, 'a lance-point'). If we conceive a curve to be generated by a moving point, then a cusp is where the point suddenly stops and

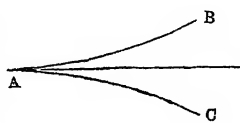

Fig. 1.

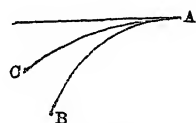

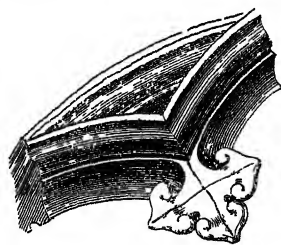

Fig. 2.

returns for a time in the same general direction as that in which it was moving when it reached the cusp point. A later name is 'spinode.' When two branches (as BA, CA) meet a common tangent without extending further, the point of contact is a cusp. Fig. 1 is an example of the first species, and 2 of the second.

**Cusparia.** See ANGOSTURA BARK.

**Cusps**, curved projections or featherings in Gothic tracery, arches, panels, &c. They began in the Early English period, when they projected from the flat soffit of the arch; but they were soon comprised in the mouldings, and generally spring from the inner splay or cavetto. In Decorated and Perpendicular work the points were lengthened, and were frequently ornamented with flowers, heads, &c.

Cusp.

**Cusset**, a small town in the French department of Allier, 2 miles NE. of Vichy, with two mineral springs; pop. 6000.

**Cusso, KUSSO**, or CABOTZ (*Brayera anthelmintica*), a small Abyssinian tree of the order Rosaceae, the dried flowers of which have been long infused in Abyssinia as an anthelmintic. As *Flores Kusso* they were introduced in 1874 into European pharmacy, owing to their efficacy in the removal of tapeworm; but being inferior in this regard to male fern, the drug is now little used.

**Cust, ROBERT NEEDHAM**, was born in 1821, at Cockayne-Hatley, Bedfordshire, studied at Eton, and entered the Indian civil service. He held various important administrative and judicial posts in North India, in 1864–65 was a member of the legislative council, and returned to England in 1869. He was a member of many learned societies at home and abroad, contributed extensively to their Transactions, and published some sixty works on the

modern languages of the East Indies (1878), of Africa (1882), and of Oceania, as well as *Linguistic and Oriental Essays and Sketches of Anglo-Indian Life*. He died 28th October 1909.

**Custard**, a composition of milk or cream, eggs, &c., sweetened with sugar, and flavoured according to taste. Custards are of various kinds, such as plain, baked, lemon, orange, almond, coffee custards, &c. For a plain custard, take four eggs and beat them well with two tablespoonfuls of flour and a little cold milk. Season this with sugar, ground cinnamon, grated lemon-peel, and pour on a pint of boiling milk, stirring all the time. It may be either baked or boiled. If more eggs are used, the flour may be omitted. Flavouring ingredients may be added according to taste.

**Custard Apple**, the name commonly given in the West Indies and other tropical countries to the fruits of certain species of Anona (order Anonaceae, allied to Ranunculaceae). Some of the fruits of this genus are among the most delicious produced in tropical countries, as the Cherimoya (*A. cherimolia*), and even the sweet sop (*A. squamosa*) and the Common Custard Apple (*A. reticulata*), which is a native of America, but is now very common throughout the East Indies. It is a large, greenish, or dark-brown, roundish fruit, sometimes from its size and appearance called Bullock's Heart in the West Indies; the tree is of considerable size. Some other American species and varieties are sometimes called custard apples, and two or three which are natives of Western Africa. *A. muricata*, the sour sop, *A. (Asimina) triloba*, the papaw-tree of the warmer parts of North America, and *A. palustris*, the dog or alligator apple of the West Indies, may also be mentioned. *A. laurifolia* grows in Florida and the West Indies; its large fruit is hardly eatable.

**Custer**, GEORGE ARMSTRONG, American soldier, born in Ohio in 1839, graduated at West Point in 1861, and served with distinction through the civil war, retiring with the rank of major-general. He afterwards held various cavalry commands in the west, and several times defeated the hostile Indians. On 15th May 1876, with a force of 1100 men, he attacked a body of Sioux, afterwards found to number some 9000, encamped on the Little Big Horn, in Montana, and he and his entire command were destroyed. See his *Life* by Whittaker (New York, 1878), and McLaughlin's *My Friend the Indian* (1910).

**Custom**, in law, is either general or particular. For general customs, see COMMON LAW. In order to establish particular customs as law, they must be proved by verdict of a jury, except the custom of the city of London, which is proved by certificate by the lord mayor, aldermen, and recorder. A particular custom must, like a general custom, be established as in force for a time whereof the memory of man runneth not to the contrary. A custom must have been uninterrupted and peaceable, reasonable, and certain; compulsory—i.e. not in the option of every person whether he will use it or not—and consistent with other customs.

The customs and usages of England were adopted by the United States government at its foundation as far as applicable to the condition of the country, and have the effect of positive law. They cannot be set aside by implication, but only by statutes. Customs and usages are frequently invoked in the interpretation of positive law, particularly when a conservative interpretation is required. A marked instance of this is found in the interpretation of generic words used in the federal and state constitutions and laws, so as to deprive women citizens of the right to the elective franchise in a government founded upon equality of citizenship, and to

restrict their industrial sphere. See CUSTOMS DUTIES.

**Customs Duties**, the portion of the revenue derived from a tax on imports. In some countries, customs duties are imposed on certain exports also. The origin of the term is connected with the long conflict between the crown and parliament as to the right of taxation, although the practice it signifies is as old as the Roman empire, and is even to be traced among the ancient Greeks. To meet the claims made by the House of Commons to the exclusive right to vote all supplies, it used to be maintained that there were certain duties on exportation and on importation to which the crown had acquired a right by *custom* (although it is certain that customs duties existed in England prior to the Norman Conquest), and after the power of parliament over this branch of taxation had been fully established it retained its old name. This tax, which originally was a sort of premium of insurance for protection from robbery, after the excise came in force was always applicable distinctively to goods changing place. There were customs not only upon things leaving and things coming to the British dominions, but also upon commodities transferred from one part to another. In Scotland the duty on commodities imported into any town from a foreign country was called the great custom; and the duty charged by a burghal corporation on commodities coming within its walls from the country districts was called the small or petty customs. After 1707 the Scottish customs duties became the same as those of England. At present the term customs duties applies in the United Kingdom solely to the tax levied on commodities imported from abroad.

The tax on imports was of old a simple percentage, familiarly known to the readers of English history as 'tunnage and poundage,' from the method in which it was levied on the tun of wine, or the pound *ad valorem* of other merchandise. These were subsidies granted first to the crown, and then for the maintenance of the authority and dignity of the state. That is to say, they were forms of public revenue; and many complications arose by the additions and alterations of successive governments. Out of this confusion, no doubt, arose the belief that customs duties might be utilised for fostering domestic industries and discouraging foreign competition. When it came to be held as an established principle, with regard to any trade, that the customs should be adjusted in such a manner as either to aid or to impede it, the regulations regarding that trade alone would have complexity enough for a whole code of customs laws, the original object of which was mere revenue. The more complex the arrangements, the more open were they to the operations of the smuggler or defrauder, and, consequently, regulation had to be added to regulation, till the whole became a chaos. Frequently the duties were such as to act as a prohibition to importation, and they always added a heavy increase to the price. Sometimes there would be relaxations in favour of the produce of British colonies, and sometimes of some favoured country with which Britain had a treaty of reciprocity. Then, to encourage trade and manufactures, it was considered politic to allow goods to be imported for re-exportation abroad, or to be imported for the purpose of being worked up into a manufacture, and there would be a difference between the extent of encouragement granted to that manufacture if it were for home consumption or for exportation. The method in which such relaxation was accomplished was at first by charging the duty on the importation, and afterwards repaying it by what was called a 'drawback;' and this was subse-

quently accomplished in an easier method for the importer, by allowing him to 'bond' the goods in the government warehouses until the duty was paid, or the conditions which dispensed with it fulfilled. An ordinary importer was also allowed to 'bond' his goods, instead of being compelled, as in the old times, to pay duty on arrival of the vessel whether he had sold his cargo or not. See **BONDED WAREHOUSES**.

In the year 1825 the laws of the British customs were consolidated into some half-dozen statutes. It will give a conception of the confused and cumbersome condition into which the system had merged, to note that the number of acts repealed on the occasion of the consolidation was 443, and it was afterwards discovered that several had been omitted. There was still a long list of customs duties; but the free-trade legislation of 1846 cleared away a great mass of this burden on the commerce of the country, and there has been steady abbreviation of the list of duties or Tariff (q.v.). One by one, articles of food have been exempted; and nearly the whole customs revenue is now derived from spirits, wine, tobacco, tea, sugar, coffee, cocoa, and dried fruits. The tendency has for some time been to concentrate the customs duties on a few articles, and yet they supply an enormous amount of revenue. The British revenue for the financial year 1921-22 was £1,124,900,000, and to this amount the customs contributed £129,100,000. Down to 1845 the tariff included some 1200 articles.

The defects which, according to the doctrines now prevalent in Great Britain, are to be avoided in a code of customs, are—1. The prohibition or discouragement of the importation of useful commodities; 2. Encouragement to the smuggler; and 3. Loss of revenue by raising the duty to the height which discourages importation. Under the first head, see **CORN LAWS**, and **FREE TRADE**. The second is connected with the view that on stimulants the duty cannot be too high, even though it should greatly impede their importation; but on the other hand, if the smuggling trade be encouraged, the stimulant is not only obtained without any contribution to the revenue, but the people become demoralised and trained to crime. Under the third head a memorable example was furnished by the old sugar-duties of France, which were so high that the native agriculturists could make sugar from beet-root cheaper than the duty-paid foreign sugar.

The collection and general management of British customs duties is under one great central department of the government in London. The office of receiver-general was in 1871 united with that of the comptroller-general, and in 1909 the Excise Department, formerly under the Inland Revenue Department, was united with the Customs Department. The Board of Customs and Excise is under a chairman, deputy-chairman, and commissioners. The annual cost of administration of the Board of Customs and Excise is £2,600,000. See **Atton** and **Holland**, *The King's Customs* (1909).

In the United States the number of dutiable articles is large. Of the total imports the dutiable have nearly half the value of the free goods. In the years 1880-1921 the total imports had a value of from \$668,000,000 to \$3,654,000,000, and the customs duties varied from \$186,500,000 to \$308,600,000, being, next to internal revenue, the largest item in the total national revenue. See also **TAX, EXCISE**.

**CUSTOM HOUSE** (Fr. *douane*, Ger. *Zollamt*), the office at a seaport or frontier where the customs duties are paid, vessels entered and cleared, &c. In England the custom-house officer has the right of personal search only when he has good cause to suspect that contraband goods are concealed about the person. See **SMUGGLING**.

**Custos Rotulorum** (Lat., 'keeper of the *rotuli* or rolls') is the person appointed by the crown to keep the records of the county sessions. The office is an ancient one, and can only be held by a justice of peace. In fact it is usually held by the lord-lieutenant. In practice the rolls are kept by the clerk of the peace, an officer appointed by the *Custos Rotulorum*.

**Custoza**, a village 10 miles SW. of Verona, where the Italians have twice been utterly defeated by the Austrians. On 23d-25th July 1848 Charles Albert was routed by Radetzky with a smaller force, and retreated behind the Mincio; and on 24th June 1866, Victor Emmanuel with 130,000 men was defeated by the Archduke Albert with 75,000 men.

**Cüstrin**. See **KUSTRIN**.

**Cutch** (*Kachchh*), an Indian state within the boundary of Bombay, stretches along the Gulf of Cutch and the Indian Ocean between Gujarat and Sind. Excluding the Rann of Cutch, it is 160 miles long from E. to W., and 30 to 70 broad from N. to S. The state, exclusive of the Rann, consists of 7600 sq. m., is the belt on the seashore, touching Sind, of which it may be regarded as a physical continuation, on the north-west, and being separated by a detached portion of the Rann from Gujarat on the south-east. While the southern edge of this belt is merely a sandy desert, the northern section, traversed lengthwise by two parallel ranges of hills, presents, amid much sterility, many fertile tracts, which yield cotton, rice, &c., and feed a large stock of horses, kine, buffaloes, and camels. The grand defect of the country is the scarcity of water. The mineral productions are coal, iron, and alum. The traces of volcanic action are numerous, and earthquakes also have recently occurred, as in 1819, 1844, 1845, 1864; that of 1819, besides shaking every fortified city to its foundations, and destroying many hundred lives, changed the level of part of the Rann. Pop. (1891) 558,415; (1901) 488,022, the reduction being due to the famine of 1899; (1911) 513,529; (1921) 484,547. The ruler is styled the Maharao (since 1918); about 200 feudatory chieftains are under him. The capital is Bhuj.

The *Rann* or *Runn* of *Cutch*—subdivided into two parts, the smaller, of nearly 2000 sq. m., on the east, and the larger, of 7000 sq. m., on the north—is a desert, being mainly caked, hard ground during the dry season, and then in turn a sort of shallow lake formed by the heavy rains and pent-up tides of the south-west monsoon. It is supposed to have been originally a permanent inlet of the ocean, and to have had its level raised by some such convulsion of nature as that which marked the year 1819. The periodical disappearance of the waters leaves behind it one continuous crust of salt. This dreary waste has a few elevated spots on which a little vegetation grows. Herds of wild asses and clouds of flies are its only inhabitants. A scheme for reclaiming much of this area was approved by the authorities in 1906.

**Cutch**. See **CATECHU**.

**Cuthbert**, ST. OF DURHAM, was one of the three great saints of England in the middle ages, the other two being St Edmund of Edmundsbury, and St Thomas-a-Becket of Canterbury. St Cuthbert was born about 635. A legend, which was long generally believed, tells that he was born in Ireland, and drew his lineage from one of the petty kings of that country; but another tradition fixes his birth in what is now Berwickshire. When the light of record first falls upon him, he was a shepherd boy in the kingdom of Northumbria, which then stretched northwards to the Forth. In 651, while watching his flock by night on the heights of Lauderdale, he believed that he saw the heavens

open, and a company of angels descend upon the earth, and again ascend to heaven, carrying with them the soul of St Aidan, the pious Bishop of Lindisfarne, or Holy Island. The vision determined him to become a monk, and in the same year he entered the monastery of Old Melrose, of which St Boisil was then provost or prior, and St Eata abbot. When the latter removed to the newly-founded monastery of Ripon, Cuthbert accompanied him, and was appointed to the office of superintendent of the guests. In consequence of the dispute as to the keeping of Easter, which was then raging, Eata returned to Melrose, and Cuthbert, having accompanied him, was on the death of St Boisil in 661 elected prior of the monastery. While in this office, he distinguished himself by his assiduity in visiting the surrounding country, and especially the remoter mountain hamlets, sometimes on horseback, but oftener on foot, and labouring by his teaching and example to reclaim the people from the superstitious or pagan rites into which they had fallen. After a few years spent in this way, he left Melrose for the island monastery of Lindisfarne, of which he became prior, his old master, St Eata, being abbot. Longing for an austere life even than the monastic, he quitted Lindisfarne in 676, to become an anchorite, or solitary recluse, in a hut which he built with his own hands on House Island, one of the Farne group. Here, in 684, he was visited by Ecgfrid, king of Northumbria, Trumwin, then bishop of the Picts, and other great men of the north, who came at the request of the synod of Twyford to entreat that he would accept the bishopric of Hexham. He reluctantly complied with their wishes, but shortly after exchanged the see of Hexham for that of Lindisfarne. Still thirsting after solitude, at the end of two years he resigned his bishopric, and returned to his hut, where he died on the 20th of March 687. The anniversary of his death was a great festival in the early English Church, which commemorated also the 4th of September, as the anniversary of the day on which his body was translated to Durham. The influence which St Cuthbert exercised upon his age seems to have been due chiefly to his fervent piety and extraordinary asceticism. The gift of a persuasive tongue is ascribed to him, and he would seem to have had skill and prudence in the management of affairs, but nowhere is there any trace of his learning.

The fame of St Cuthbert had been great during his life; it became far greater after his death. Churches were dedicated to him throughout all the wide country between the Trent and Mersey on the south, and the Forth and Clyde on the north. It is stated that when his tomb was opened at the end of eleven years, his body was found incorrupt, and so, for more than 800 years, it was believed still to continue. It remained at Lindisfarne till 875, when the monks, bearing it on their shoulders, fled inland from the fury of the Danes. After many wanderings it found a resting-place at Chester-le-Street in 883. It was transferred to Ripon in 995, and in the same year it was removed to Durham. Here, inclosed in a costly shrine, and believed to work daily miracles, it remained till the Reformation. The grave was opened in 1826, when a coffin was found to inclose another, which there was reason to suppose had been made in 1104; and this again inclosed a third, which answered the description of one made in 698, when the saint was raised from his first grave. This innermost case contained, not, indeed, the incorruptible body of St Cuthbert, but his skeleton, still entire, wrapped in five robes of embroidered silk. Fragments of these, and of the episcopal vestments, together with a comb and other relics, found beside the bones, are to be seen in the cathedral library.

The asceticism which distinguished St Cuthbert in life, long lingered round his tomb. Until the Reformation, no woman was suffered to approach his shrine. His wrath, it was believed, was equally prompt to avenge every injury to the honour or possessions of his church. A cloth said to have been used by St Cuthbert in celebrating mass was fashioned into a standard, which was believed to insure victory to the army in whose ranks it was carried. Flodden was only one of many fields in which the defeat of the Scots was ascribed to the banner of St Cuthbert.

The Life of St Cuthbert was twice written by the Venerable Bede. Other ancient authorities are Symeon of Durham, and Reginald of Durham. See Raine's *St Cuthbert* (1828), Archbishop Eyre's *History of St Cuthbert* (1849; 3d ed. 1887), and Fryer's *Cuthbert of Lindisfarne* (1880).

The name *St Cuthbert's Beads* has been popularly given to single joints of the stems of fossil Crinoidea (q.v.), which being hollow could be strung on thread, and so made into a rosary.

**Cuticle**, a sheath formed outside a layer of cells, either by their secretory activity or by a modification of their external portions. In the strict sense, a cuticle is not in itself cellular, but consists of the products or of the modified portions of underlying cells. The thin envelope which may be readily stripped off a leech or earthworm when killed in spirit supplies a convenient example. A cuticle is usually formed outside relatively passive cells, but even ciliated Epithelium (q.v.) may have its cuticular outer layer through the pores of which the cilia emerge. By continuous modifications of the cells considerable thickness of cuticle may be developed—as e.g. the hard lining of the gizzard in many birds. By chemical modification of a well-developed cuticular formation very varied protective and offensive skin-structures often result. Thus the peculiar gelatinous, cellulose-containing tunic of Ascidians is for the most part a cuticle; the shells of molluscs are cuticular formations plus lime; the rasps of snails are formed from cuticle; the hard armour of Arthropods is a cuticle associated with the formation of Chitin (q.v.); the bristles, jaws, and firm sheaths of many worms are also cuticular, and so on. For the use of the term in special connections—e.g. the cuticle of the hair or of the teeth, see special articles. The term must not be confused with *cutis*, one of the names for the under skin or *dermis*; nor should it ever be used as equivalent to skin. See CELL, EPITHELIUM, SKIN.

**Cutlass**, a sword nearly 3 feet long, broad and nearly straight, mostly used by seamen of the royal navy. The word, from French *coute-las*, Latin *cultellus*, is also found in the form *curtal-axe*, which is not connected with *curtal* or with *axe*. See SWORD.

**Cutlery**, the general name given to such cutting instruments as knives, scissors, razors, as well as forks. The making of axes, chisels, and saws is rather the business of the tool-maker than of the cutler. Shells, flints, and other sharp-edged stones formed the rudest and most ancient cutting instruments, and early traces of human existence in Britain and elsewhere are associated with stone 'celts' and other weapons and cutting implements. These were followed by bronze weapons and other articles, including reaping-hooks. In the museum of Bologna there are ancient Etruscan bronze knives carved in form somewhat like modern reaping-hooks, and in the great Naples collection of objects from Pompeii and Herculaneum, there are sickles, bill-hooks, knives, lancets, and spring-shears, some of which are made of iron or steel, as well as of bronze. These are of course ancient Roman.

Bronze, like steel, can be hardened, but by opposite means, since it is softened by sudden and hardened by slow cooling. The ancients appear to have been great experts in the tempering of bronze.

The Anglo-Saxons had knives somewhat resembling a razor-blade. They had forks also; but it would appear that these were employed for serving, not for use in feeding. The custom of using forks for eating with came from Italy, and was not known in England till the reign of James I. Before that, people fed themselves with their fingers, as is still the practice in the East. The Persians so much prefer this custom that they contemptuously call a fork a claw. Up to the end of the 15th century knives do not appear to have been much used at table, but as in those days everybody carried a knife in his girdle, it probably served to cut meat with as one of its applications. Spring-shears of the ancient Roman form were the only kind known up to Norman times, and probably even till the 15th or 16th century.

The London cutlers obtained a charter of incorporation in 1417 from Henry V.; but long before that knives were made at Sheffield, as the 'whittle' of that town, or village, as it would then be, is incidentally mentioned by Chaucer. Knives, sickles, shears, and scissors are named as being made in Sheffield, when the Hallamshire cutlers were incorporated in 1624. Cutlery was not then however an English specialty; and England still imported iron and steel goods largely from the Continent; and in England, Birmingham was in the 17th century regarded as the home of smiths and cutlers. The vast increase in the size of Sheffield since 1800 shows that it is chiefly during this century that its cutlery wares have expanded from being a mere inland into that of a world-wide commerce.

*Table-knives.*—Of these the best kinds are made by hand, and have the blade of steel, while the shoulder and tang, to which the haft is fitted, is of malleable iron. From the end of a thin bar of steel, which has been carefully brought to a proper heat, the blade is roughly forged, cut off, and welded to a piece of iron for the tang and shoulder. The latter, usually called the 'bolster,' is formed by crushing the hot iron between a pair of dies, and the tang drawn out by some strokes of the hammer. After reheating, the blade is again hammered and the maker's name stamped upon it. The next stage, that of hardening and tempering, is all-important in every kind of steel cutting instrument. Raising the blade to a dull red heat and then plunging it in cold water hardens it, but at the same time makes it brittle. The brittleness is removed and the steel made flexible by the process of tempering, which consists in again heating the blade till it acquires a bluish colour, and at this moment putting it back into the water. After tempering, the knife passes to the grinder, who smooths the bolster and works the blade a little on the grindstone. But the blade still requires to be made quite straight in the smithy, and again ground. The finishing processes of lapping, glazing, and polishing follow, in which different wheels are used along with emery and polishing-powder. The lap is covered with an alloy of tin and lead, and the glazing and polishing wheels with leather. Bone, ivory, horn, and other materials are employed for the hafts, but these are prepared by a different set of workmen.

Machinery is now used for the manufacture of blades of common table-knives, in which case blade, bolster, and tang are made of one piece of steel. A few strokes of a steam-hammer shape the blade, and without reheating the shoulder is formed, but it requires to be heated again for drawing out the tang. The blade is next reheated and hammered

thin, and then the whole of the metal portion of the knife is pressed into dies to give it the exact shape and size. Grinding and the finishing processes now follow.

Very cheap knives are made by simply 'flying' (i.e. pressing into dies) the blade and tang out of a cold sheet of steel at one operation, and dispensing with a shoulder.

*Forks.*—These are made from a bar of steel three-eighths of an inch square. The forger begins by forming the tang, shoulder, and shank. He then beats out flat a square piece left at the end for the prongs. In the next stage the whole is heated till it is soft, and pressed with some force between two halves of a die, which roughly form the prongs. The fork is afterwards filed, ground, brightened, and hafted. Forks of an inferior kind are cast.

*Spring-knives.*—Pocket-knives are of much more modern date than those used at the table. The earliest piece of cutlery made at Sheffield, or perhaps in England, was called a *thwytel* or *whittle*, and served for a weapon as well as for other purposes. At a later time the jack-knife appeared, which was made to shut into a groove in the handle, but had no spring. Some spring-knives are believed to have been made as far back as the beginning of the 17th century; but it was not till about 1820 that a spring-knife of the type now so much in use was invented by the first Lord Wharnclyffe, or at least was named after him. The process of making the blade of a spring-knife does not differ much from that already described for a table-knife. Sometimes the springs are forged, but others are 'fied'—i.e. formed at a single blow out of a piece of steel. The inner scales of the haft are made of brass or iron, and sometimes of a more expensive metal; while a still greater variety of material, such as hard wood, horn of various kinds, ivory, bone, and tortoise-shell, is used for the outer scales.

*Razors.*—The use of the razor goes back to a very remote period. It is referred to in the book of Numbers, and was used by the ancient Egyptians as well as by the Greeks and Romans. The blade of a razor is forged from a piece of steel of the thickness of its back, and half an inch wide, the concave sides being formed on the rounded edge of the anvil. In the smithing process which follows, the workman hammers it to make it compact, and at the same time shapes it into proper form. It is next ground, hardened, and tempered; after which it is once more ground, and then lapped, glazed, and polished. The best qualities of razors are made of the finest cast steel, and are manipulated with great care in every stage of their manufacture. But there is always some uncertainty about the quality of a razor even when made with the utmost skill and care and from the best material. Perhaps this explains why high-priced razors are not in great demand, at least in Great Britain.

*Scissors.*—A blade is forged from a flat bar of steel, and this, including a bit for the shank and bow, is then cut off. Next a hole is punched for the bow to admit of its receiving the point of a small anvil upon which it is roughly shaped. After reheating, the bow is further shaped, the shank formed, and both filed. The joint is now squared, and the hole bored for the rivet or screw. Grinding and smoothing of the blade follow, and then the two are screwed together. If they work smoothly, they are ready for hardening and tempering, but the screw is first removed and the two halves wired together. Afterwards the scissors are ground and passed through the finishing processes already described.

Only the more important processes have been mentioned. The subdivision of labour is very fully

carried out in the cutlery trade, so much so that the man who forges the pen-blades does not forge the larger blades for the same knife. It is the same with those who grind the blades. Including those of a comparatively trivial nature, an ordinary three-bladed pocket-knife goes through more than a hundred processes. Moreover, the use of machinery is extending. Cutting, punching, grinding, and so on can be done much more rapidly and accurately by machines than by hand. Especially is this so since the introduction of stainless steel (containing chromium) and of stainless iron.

The grinders in former years suffered so much from the fine particles of stone and metal which pervaded the atmosphere of the workshops that their average age did not exceed twenty-nine. This was especially the case with those engaged in dry-grinding, which, for example, was that used for forks. In wet-grinding, the water on the stone prevented the escape of particles of matter through the room. The evils of dry-grinding it has been sought to remove by the application of a fan with a properly constructed flue, which withdraws the grit and steel dust as it is produced.

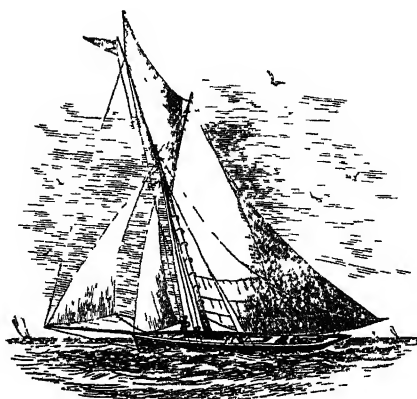

The manufacture of 'scales,' or hafts, or handles, is to a large extent a separate trade. Ivory, wood, bone, &c. are all employed for the purpose. Ivory was long so popular a material for knife-handles that Sheffield has in some years consumed the tusks of 20,000 elephants; but owing to its increasing scarcity and price, various substitutes are now employed. In trading with savage people it is curious how they will sometimes unexpectedly reject a useful article on account of its colour. For example, the Fiji Islanders a few years ago, if not now, would on no account accept in baiter a white-handled knife, but would readily take one with a black handle.

In cutlery France and Germany are now competing with England in many foreign markets; but the trade has again shown a tendency to increase in Sheffield. The manufacture is now also extensively carried on in the United States. In France the headquarters of cutlery are at Thiers, Langres, Nogent, Châtellerauld, and Paris, where the finest surgical instruments are made. Solingen is called 'the German Sheffield;' but Remscheid, Suhl, Schmalkalden, and many other towns produce knives and the like. Swedish razors are famous. See also SWORD, STONE AGE, &c.

**Cuttack** (*Kataka*, 'the fort'), the capital of a district in Bihar and Orissa, stands immediately below the bifurcation of the Mahanadi, thus occupying the apex of the delta of that river, a position advantageous both in military and commercial respects. The city, which is 220 miles SW. of Calcutta, is chiefly notable for its filigree-work in gold and silver. Ravenshaw College is an external college of Patna University. Pop. 53,000.—The district is the central one of the Orissa division, and has an area of 3654 sq. m., and a pop. of 2,000,000.

**Cutter** is a name given to two kinds of small vessels. The cutters used by yachtsmen and revenue cruisers, which are built with especial reference to speed, have a single mast, and a straight running bowsprit that can be run in on board occasionally. They are much like sloops in rig, but have larger sails. Such small vessels occasionally venture on long voyages. In 1857 the *Charter Oak*, a cutter of 23 tons, crossed the Atlantic from New York to Liverpool. In 1865 the *Alert*, a cutter of 56 tons yacht measurement, made the voyage from England to Sydney (Australia) in 108 days, including 5 days' detention at the Cape of Good Hope. From that time to this, long voyages with vessels of this class, especially across the Atlantic, have been matters of common

occurrence. See YACHT; for the other kind of

Cutter.

cutters, see BOAT.—In the United States, very long sleds, for coasting, are called *cutters*.

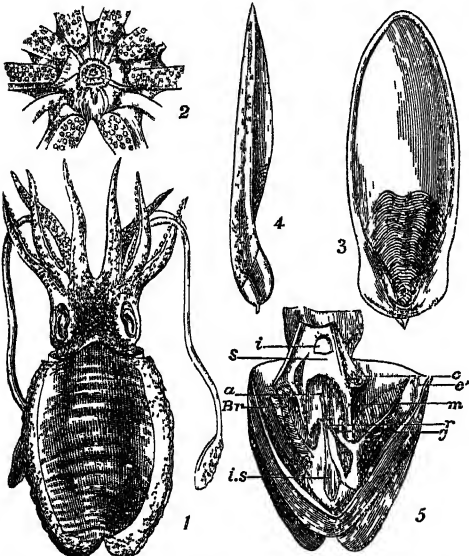

**Cuttings** are branches or portions of branches of trees or shrubs, employed to produce new plants, by burying the lower end in the earth so that new roots may arise from the nodes. Nothing is more easy than to propagate willows, fuchsias, pinks, geraniums, currants, gooseberries, &c. in this way; but many other plants, commonly propagated by cuttings, require greater attention on the part of the gardener, warmth, a uniform damp atmosphere, and shade. The term cutting is, however, usefully extended by most horticultural writers to any part of a plant which can be separated to become an individual similar to its parent; thus some plants may be propagated most readily from simple leaves or portions of leaves, others from a segment of stem bearing a single leaf with a bud at its base, others from offshoots at the base of the parent plant, some again from the younger shoots, and others from partially ripened wood, and so on. Hence there is room for considerable experience and skill, and detailed instructions should be sought by the amateur florist in works on horticulture (e.g. Johnson's *Dictionary of Gardening*). The most convenient general method, however, is to strike cuttings in well-drained shallow pots or boxes of silver sand overlying a little sandy peat or loam; shade and water being applied with discretion, and bottom heat only in special cases, which of course include the majority of stove plants. Hardy fruit-trees may be best propagated by cuttings taken after the fall of the leaf, and planted on the north side of a wall, but not so close as to be constantly in shade.

**Cuttle-fish** (O.E. *cuðele*), strictly speaking, a member of the genus *Sepia*, more generally applied to any Cephalopod (q.v.). A brief account is here given of the structure, life-history, and habits of the common British species (*Sepia officinalis*, Linn.), with a tabular indication of its relationships.

The *Sepia* (fig. 1) measures from six to ten inches in length, and its colour varies from pale gray to dark brown or neutral tint. The body is oval, flattened from above downwards, and contained in a tough muscular sac (mantle), which expands along the whole of either margin into a narrow fin. The integument consists of a single layer of cells, lying upon connective tissue, in which are imbedded 'chromatophores,' or cells charged with variously coloured pigment-granules. By expansion of the cell the pigment is diffused, and by its contraction concentrated, hence the rapid flashes of changing

colour for which the cephalopoda as a whole are so remarkable.

The head is broad, and contains a cartilage of complex shape which protects the central nervous system, and forms a socket on either side for the large eye; this has a bright green lustre during life, the black pupil is shaped like the Greek letter  $\omega$ , and there are two eyelids, the upper coloured, the lower white. The front of the head is occupied entirely by the bases of the arms and the mouth. The former are ten in number, eight of

1, *Sepia officinalis* from the dorsal aspect; 2, view of the Mouth, showing its Lip and the bases of the Arms and Tentacles; 3, the Shell seen from the ventral surface; 4, the same in lateral view; 5, the Animal with the Mantle divided in the middle line to expose the Branchial Cavity:

*s*, siphon; *i*, its valve; *c*, pit in the base of the siphon; *c'*, prominence on the mantle which fits into it; *m*, muscle passing backwards from the siphon to the mantle; *a*, termination of the intestine. *Br*, gill; *r*, renal opening; *g*, genital opening; *u. s.*, ink sac. At the base of the right gill a portion of the membrane has been removed to show the branchial heart.

them being alike, oblong in transverse section and tapering off to slender extremities; they have the surface which is turned towards the mouth covered with suckers in four longitudinal rows. The suckers consist of a muscular periphery, strengthened by a horny ring; a fleshy pad acts like a piston in the base of this latter. Each sucker is mounted on a short flexible stalk. The two remaining arms, known as 'tentacles,' occupy the interspaces between the ventral arms and those next to them. They are twice as long as the others, and have a cylindrical stem, slightly expanded at the extremity into a club furnished with larger and smaller suckers. They can be withdrawn into pockets situated beneath the eyes, and are carried in this position when not in use. The mouth (fig. 2), situated in the centre of the roots of the arms, is surrounded by a lip with seven prominent angles, which bear small suckers in some species, and have been compared to rudimentary arms. Projecting from it may be seen the two black horny mandibles, shaped like those of a parrot, but with the lower overlapping the upper.

On the lower aspect of the animal, between the muscular sac and the body proper which contains the viscera, is a hollow space, the 'branchial' or

'mantle-cavity.' When this is opened by a longitudinal incision it is seen to contain the following structures (fig. 5). Anteriorly is the base of the 'siphon,' or 'funnel,' *s*, a conical tube containing a valve, *i*, through which water can be forcibly expelled by the contraction of the mantle. At its posterior margin on either side is an almond-shaped depression, lined with cartilage, *c*, into which fits a prominence on the inner surface of the mantle, *c'*, an arrangement which largely contributes to the solidarity of the body as a whole. Lying along the middle line is the terminal portion of the intestine, *a*, furnished with two small flap-like appendages of uncertain function, and on either side, a little farther back, is a small papilla, *r*, upon which the kidney opens, and on the left side only, the genital orifice, *g*. Two large gills, *Br*, are situated in the lateral recesses of the mantle-cavity, each consisting of an arterial stem running up the attached side, and a venous stem passing down the other aspect, the bulk of the organ being made up of a series of folds passing transversely from one to the other, and richly supplied with vessels containing the blood to be aerated. Respiration is carried on by rhythmic contractions of the mantle, in consequence of which water enters at either side, passes over the gills, and is expelled by the siphon; this takes place about seventy times in a minute.

On the dorsal side of the animal, immediately beneath the integument, is a closed sac which contains the internal shell (cuttle-bone, sepistostere, figs. 3, 4). Speaking generally, this may be said to be of an elongated spoon or boat shape; it consists of a horny lamina, which gives it its characteristic outline, extending also into the small cone at the back, which in many species is much larger than in the one now under consideration, and has been compared with the guard of the Belemnite (q.v.). On the dorsal surface is a granular calcareous deposit; while the concave ventral aspect of the spoon is occupied by a series of layers of calcareous matter, which are deposited in succession and do not entirely cover each other, so that the hinder portion of this surface presents a striated appearance due to their parallel margins. This part of the shell is porous and extremely light, the interstices being filled with air. These shells are imported into Liverpool in some quantity, and ground into fine powder to form a dentifrice.

**The Digestive Organs.**—Within the beak above alluded to is a solid muscular mass (buccal cone), part of which is devoted to its movements. Through its centre passes the gullet, the lower wall of which bears a most remarkable organ, the tooth-strap or 'radula'; this consists of seven longitudinal rows of horny teeth, which are secreted by certain special cells of the epithelium, and whose apices are directed backwards. They can be moved to and fro by appropriate muscles. Behind the buccal cone the oesophagus bears the salivary glands, and still farther back it opens into a round saccular stomach with muscular walls. A large bilobed gland, commonly called 'liver,' but having the functions of a pancreas, is situated on the oesophagus. Lying parallel to the terminal portion of the intestine is the 'ink-bag,' *u. s.*, a hollow gland opening near the anus, and furnishing a deep-brown fluid, which is ejected by the animal when alarmed in order to conceal its retreat. When genuine, the pigment known as 'sepia' is prepared from it.

**The Circulatory Organs.**—The heart is situated posteriorly, and consists of a pear-shaped sac which receives on either side a vein from the gills, dilated just before its termination into a muscular contractile antechamber or auricle. It gives off an artery anteriorly to supply the head and arms, and one posteriorly to the abdominal organs. The

blood, after being distributed throughout the body, is collected in veins which traverse the walls of the kidneys and pericardium, and eventually pass to the gills, at the base of which a muscular dilatation (branchial heart) is situated, serving to effect the circulation of the blood through the gills.

The *Nervous System* consists of the three pairs of ganglia common to the Mollusca concentrated round the oesophagus. One pair (pedal) supplies the arms and siphon; a second (plemo-visceral) the gills, viscera, and mantle; a third (cerebral) the head and eyes. In the mantle on either side is a large nervous mass (ganglion stellatum) situated on the pleural nerve, and supplying the mantle. In addition to these parts, and connected with them, there is a system of so-called 'enteric' nerves, springing from the buccal ganglia, which lie on the oesophagus just in front of the cerebral ganglia.

Of the *Organs of Sense* the eyes are the most conspicuous. They occupy depressions in the head cartilage, the hinder part of which is occupied by the optic ganglia, ocular muscles, and a white glandular substance of unknown function. The retina consists of an inner layer of rods with swollen bases, and an outer layer of nucleated cells with a limiting membrane between them. The retinal chamber is closed in front by a spheroidal lens, made up of an inner and outer portion, which are secreted separately by an epithelial structure occupying a groove round its equator. In front of the lens is the iris, supported by a cartilage and containing a sphincter muscle; the outer surface of the whole is formed by the transparent cornea, which, though continuous in the Sepia, is perforated in a large group of Cephalopoda (Cegopsida).

The so-called *ears* are a pair of small closed vesicles, imbedded in the head-cartilage, and supplied by nerves which, though apparently springing from the pedal ganglia, really have their origin in the cerebral. The function of these organs is almost certainly to maintain the equilibrium of the body. A ciliated pit, usually considered to be *olfactory* in function, lies behind each eye.

*Generative Organs.*—The sexes are separate. The testis and ovary are both single and situated in the hinder part of the body; the latter lies in the visceral sac or pericardium above described, the former in an almost closed diverticulum of it. The eggs have a tough capsule, with a projection at one end and a kind of handle at the other by which they are attached in bunches to a twig of seaweed or other similar substance. As in the hen's egg, the proportion of nutritive to formative yolk is very large, and the embryo, as it develops, comes to stand head downwards on the former.

*Habits.*—The animals are found in littoral regions or in moderately deep water; ordinarily they rest horizontally on or near the bottom, the fins gently undulating, the tentacles retracted, and the arms depressed (see cut at CEPHALOPODA). Progression may take place by means of the fins with considerable rapidity in either direction, the funnel being turned so that the stream of water issuing from it assists in propulsion; rapid darts backwards when the animal is alarmed are brought about either by the sudden ejection of water through the siphon, or by spreading out and reuniting the arms. When feeding, the Sepia remains motionless till its prey is within striking distance; then the dorsal arms are raised, the others open out sideways, the tentacles are shot forth with the rapidity of lightning, and the victim seized between their terminal clubs (see cut at CEPHALOPODA).

*Distribution.*—Over seventy recent species of Sepia have been described, of which about sixty may be regarded as valid. By far the greatest number belong to the Indo-Malayan region, whilst,

with one exception, none occur on the shores of the New World. About a dozen fossil forms have been recorded from Tertiary deposits. For large and fabulous Cephalopods, see OCTOPUS, SEA-SERPENT.

**Cutty Stool.** See STOOL OF REPENTANCE.

**Cutworm,** a term used loosely of worms or grubs destructive to cabbage, beans, &c.

**Cuvier, LÉOPOLD CHRÉTIEN FRÉDÉRIC DAGOBERT,** better known as GEORGES, a great comparative anatomist, the first to unite the palæontology of extinct forms with the anatomy of the extant, important also as an educationist, was born on the 24th August 1769, in the town of Montbéliard, at that time belonging to Wurtemberg. His ancestors were Protestant refugees from the Jura. He was destined by his parents for the church, but early exhibited a predisposition for natural history. In his education at Stuttgart, he came under the happy influence of the botanist Kerner and the zoologist Kielmeyer. At the age of eighteen he became tutor in a family living near Caen, in Normandy. There the abundant fossil Terebratulæ of the shore, the cuttle-fish and other molluscs landed by the waves, excited his eager interest, and became subjects of close study. There too he was introduced to Geoffroy St-Hilaire and other Parisian savants. Geoffroy at once recognised his abilities, and invited him to Paris. Cuvier accepted the invitation, became first assistant, and then professor of Comparative Anatomy in the Jardin des Plantes. Elected a member of the French Institute in 1795, he became in 1803 permanent secretary of the Academy of Sciences. In 1808 he undertook the reorganisation of public instruction, and shortly before the fall of Napoleon was admitted into the Council of State. After the Restoration he was made Chancellor of the University of Paris. After a visit to England in 1818, where he was received with great honour, he was, in 1819, admitted into the cabinet by Louis XVIII., and in 1826 was made grand-officer of the Legion of Honour. His decided opposition to the royal measures for restricting the freedom of the press lost him the favour of Charles X. Under Louis-Philippe he was made a peer of France (Baron Cuvier) in 1831, and in the following year he was nominated Minister of the Interior. Then his career was terminated suddenly from an attack of paralysis of which he died, May 13, 1832.

Cuvier's life was characterised by extraordinary activity. In his plans for the extension and improvement of national education, in his efforts for the welfare of the French Protestant Church, and in his scientific work, he was alike zealous and indefatigable. On every hand he gave evidence of gigantic intellect, and of honest, resolute character. He was conspicuous for an unsurpassed grasp of concrete facts, rather than for originality of suggestion or power of generalisation, and remained a vigorous and formidable opponent of the Theory of Descent.

In several departments of zoology, Cuvier's indefatigable industry and giant intelligence achieved great progress. (1) By marvellous energy in collecting, examining, and dissecting, he vastly increased the circle of accurately known forms, both living and extinct. (2) This was done, however, in a way which combined depth of insight with increasing breadth of view. He penetrated below external form to the internal structure, and not content with empirical dissection, rationalised his results in the first systematic comparative anatomy. His profound anatomical studies led him further to appreciate more clearly than heretofore the unity of the organism and the mutual dependence of its parts. In clearly defining the principle of the

correlation of organs, he recognised, to quote his memorable words, that 'the organism forms a connected unity, in which the single parts cannot change without bringing about modifications in the other parts.' (3) In his hands classification became more natural, being more thoroughly based on real similarities of structure, and less on superficial resemblances. He recognised the existence of four great types—Vertebrate, Mollusc, Articulate, and Radiate, a classification independently confirmed by the embryological researches of Von Baer. Although his four types are now known to give a false simplicity to nature, the establishing of structural classification, followed out in his subdivisions, introduced a new order in the animal kingdom. (4) Before his work, fossil forms had been very scantily known, and still less understood. His researches, however, especially among vertebrate remains, not only revealed an undreamt-of wealth of entombed forms, but disclosed to some extent the relation between the living and the dead. For the first time palæontology was linked to comparative anatomy, and the new contact brought fresh light. Yet it must be remembered that to him the Linnean dogma of the constancy of species seemed unassailable. Clear as he was in regard to the existence of fundamental and recurrent types, he was as determinedly opposed to the suggestion of Buffon, Lamarck, and others, that animals were connected by common descent.

Among Cuvier's more important works are the following: *Leçons d'Anatomie Comparée* (1801-5); *L'Anatomie des Mollusques* (1816); *Recherches sur les Ossements Fossiles des Quadrupèdes* (1812); *Discours sur les Révolutions de la Surface du Globe* (introduction to the last); *Histoire naturelle des Poissons* (1828-49), written in concert with Valenciennes. Better known perhaps than any of these is the work which has passed through so many editors' hands—*Le Règne Animal distribué d'après son Organisation* (1817), more familiar in the enlarged and elaborated form which it received under the editorship of Cuvier's school. Important too for the history of zoology are numerous éloges and historic reports delivered on various occasions throughout Cuvier's life.

See Mrs. R. Lee's *Memoirs of Baron Cuvier* (1833); Pasquier's *Éloge de Cuvier* (1833); Carus's *Geschichte der Zoologie* (1872); Haeckel's *History of Creation* (1876); Ducrotay de Blainville's *Cuvier et St Hilaire* (1890).

**Cuxhaven**, a port and watering-place, on the southern bank of the Elbe, at its mouth in the German Ocean, 72 miles NW. of Hamburg by rail. The port whence the Hamburg steamers ply when in winter the Elbe is frozen over, Cuxhaven has an old castle and a free port. Its fish trade has greatly developed. Cuxhaven belongs to Hamburg. Population, 15,000—in summer doubled by visitors.

**Cuyabá**, the capital of the Brazilian state of Matto Grosso, occupies pretty nearly the centre of South America. It stands on the left bank of the Cuyabá River, 980 miles NW. of Rio de Janeiro. Founded by gold-diggers in 1719, and wrecked by an earthquake in 1746, it is now a well-built place, with a cathedral and 34,000 inhabitants. It can be reached by the rivers Paraná and Paraguay, a voyage of 2500 miles from Buenos Aires.

**Cuyp**, or **KUYP**, **JACOB GERRITSE**, commonly called the Old Cuyp, was born at Dordrecht in 1575. Jacob Cuyp's representation of cows and sheep, battles and encampments, are clever, but his fame rests principally upon his excellent portraits. His colouring is warm and transparent; his manner, free, and spirited. Cuyp was one of the four founders of the Guild of St Luke at Dordrecht, and died after 1649.—**ALBERT CUYP**, Jacob's son, was also born at Dordrecht, in 1620.

He excelled in the painting of cattle grazing or reposing, moonlights, wintry landscapes, still waters with ships, horse-markets, hunts, camps, and cavalry-fights; and in rendering effects of warm golden sunlight he is without a rival. During his lifetime and long after, Albert's pictures, although in many respects equal to those of Claude, were held in little estimation. Opinion, however, has now changed regarding them, and a fine example of his art has realised over £5000. England is particularly rich in his works, the National Gallery possessing eight of his subjects. He died at Dordrecht, 1691.—**BENJAMIN CUYP**, a nephew of Albert, was born at Dordrecht in 1608, and became a member of the guild there in 1631. He painted biblical pieces in Rembrandt's style, and familiar scenes of country life. His best works are in the manner of Teniers. His seashores have less repute.

**Cuzco**, a city of Peru, stands 11,440 feet above sea-level, in a valley of the Andes, 345 miles ESE. of Lima. It was the ancient capital of the Incas (in whose language, says Garcilaso, Cuzco signifies 'navel'), and at the time of its conquest by Pizarro (1533) had 200,000 inhabitants. Now it has 10,000 to 15,000, but it is one of the finest cities in the republic, with a cathedral (1572-1654), a so-called university (1598), and some remnants of Cyclopean architecture.—Cuzco gives name to a department, with about 440,000 inhabitants. See **PERU**.

**Cyanamide**. See **MANURES**.

**Cyanate**. See **CYANOGEN**.

**Cyanide**. See **CYANOGEN**, **HYDROCYANIC ACID**. Gold is extracted by dissolving it in a solution of potassium cyanide, from which it is precipitated by zinc or by electrolysis. See **GOLD**.

**Cyanite**. See **KYANITE**.

**Cyanogen** (**CN**)<sub>2</sub>, although intrinsically of little importance, is one of the most interesting compounds of carbon. It was the first known compound body which was proved to be able to unite with elements in the same way as these substances unite with each other. Thus hydrogen, H, unites with chlorine, Cl, to form hydrochloric acid, and sodium, Na, unites with chlorine to form chloride of sodium, NaCl. Like these elements, H, Cl, or Na, each a single substance, the group CN, consisting of 12 parts of carbon and 14 of nitrogen, enters into combination, acting as if it also were for the time being an element; thus it forms cyanide of sodium, NaCN, or NaCy, and hydrocyanic acid, HCN, or HCy.

Cyanogen is a colourless, poisonous gas, which burns with a purplish flame. It is soluble in water, and can be condensed to a liquid, under a pressure of about four atmospheres (60 lb. per sq. inch). It may be obtained by heating the cyanide of mercury, HgCy<sub>2</sub>, when the cyanogen passes off in the gaseous state.

Cyanogen forms poisonous compounds with metals called *cyanides*, of which *cyanide of potassium* (see **POTASSIUM**) is important in photography, metallurgy, and electroplating. With hydrogen it forms the deadly prussic acid or Hydrocyanic Acid (q.v.), while it is united with oxygen in cyanic acid. When air is passed over fused barium or calcium carbide in an electric furnace, barium or calcium cyanide is formed from which the alkali salts may be prepared.

*Cyanic Acid* is a compound of cyanogen which can hardly be prepared in the free state, owing to its great tendency to decompose. It forms a class of salts called *cyanates*, of which the chief is the cyanate of potash. This salt is produced when cyanogen gas is passed into solution of potash. The formula of cyanic acid is HCNO, or HCyO.

**Cyanophyceæ**, or blue-green algae, a class of unicellular or filamentous plants, often found united together in colonies by the gelatinous swelling of the cell-wall. They are found in water, on damp surfaces of earth, rocks, trees, &c., and in symbiotic union with other plants such as fungi (see LICHENS), Azolla, and Cycads. There is a chromatophore in the form of a hollow cylinder or sphere, containing chlorophyll, phycocyan (a blue-green pigment), and sometimes phycoerythrin (a red pigment). Reproduction is always vegetative. The mass of cells formed by division may remain together in a colony. Some form resting-spores, enlarged cells with thickened walls. Modified cells, called heterocysts, are found in some filaments. These are not understood. See NOSTOC.

**Cyanophyll**, the bluish-green constituent of Chlorophyll (q.v.).

**Cyano'sis** (Gr. *kyanos*, 'blue'), lividity of complexion, with fullness of the capillaries and minute veins, especially of the face and lips. A name characteristically applied to the colour in certain cases of congenital disease or malformation of the heart. See HEART.

**Cyanotype** is a photograph obtained by the use of a cyanide. See PHOTOGRAPHY.

**Cyathea**. See TREE-FERNS.

**Cyathium**, a very curious inflorescence hardly to be distinguished from a single flower, found in some Euphorbiaceæ (q.v.). If a Spurge (q.v.) be examined, there will be found in the middle a female flower, consisting of a three-capped ovary, borne on a long stalk. It may have a perianth. Around it in five groups are male flowers, each reduced to one stamen, and marked off from its stalk by a joint, the oldest flowers being nearest the centre. Opposite these, five bracts enclosing the whole give the appearance of a perianth. Between the bracts are four horn-shaped glands which secrete nectar. The fifth gland is wanting, and the female flower dangles over in the gap. The cyathia are grouped in dichasia. In some the female flower remains rudimentary. In *Anthostema* each male flower has a perianth at the joint, and the female has also a perianth.

**Cybele** (called also *Agdistis* and *Dindymene*), an ancient goddess whose worship was universal in Phrygia, and widely spread in Western Asia as that of 'the great mother' or 'the mother of the gods.' She seems to have been a nature divinity, whose worship was attended with wild orgiastic rites, many of which were adopted by the Greeks from the eastern nations. The Greeks, moreover, identified the oriental Cybele with their ancient earth goddess Rhea, whose worship seems to have originated in Crete, where she is associated with the Curetes. Among the Romans she was considered as identical with Ops, the wife of Saturn, and mother of Jupiter. In Phrygia her priests were the Corybantes, who worshipped her noisily with drums, cymbals, and horns, dressed in full armour. The Roman priests of Cybele were often called Galli. In art Cybele is usually represented seated on a throne, adorned with a mural crown, with lions crouching to the right and left, or sitting in a car drawn by lions. See RHEA.

**Cycads**, or CYCADACEÆ, an order allied to Coniferae (see GYMNOSPERMES), and to ferns, in vegetative appearance resembling ferns and palms. The stem, which is externally covered with leaf-bases, may be so short that the crown of leaves arises little above the surface of the ground; more frequently, however, it rises to a height of a few feet, then resembling a tree-fern; and in exceptional cases (e.g. *Macrozamia Hopei* of northern Queensland) may attain a height of 50 or 60 feet. The armour of leaf-bases may be poorly

developed or wanting where the stem, as in some cycads, is entirely underground. The

foliage-leaves, which develop under the protection of reduced bud-leaves, are usually pinnate, and mostly parallel-veined, or, rather, fork-veined; but in *Cycas* we have a middle vein only, and in the curiously fern-like *Stangeria* a mid-vein with reticulated lateral branches. The leaves become more or less leathery, and sometimes very hard and spiny at the tips and on the edge. In *Cycas* the pinnæ are circinate in bud as in ferns, although the midrib is straight; conversely in *Zamia*, the leaf itself is inrolled, although the pinnæ are straight; in others, however, where both are straight, the pinnæ overlap each other from above downwards, as in the moonwort fern (*Botrychium*). A new crown is developed at intervals of a year, two years, or more. The old leaves droop, lose their pinnæ, and finally drop off, leaving the base attached. The stem is of complex internal structure, but is thickened by permanent cambium. Growth-rings answer to periods of growth and rest. It may bear lateral buds on the axils of old leaves, especially in unhealthy plants; and these may fall off and propagate the plant. Except in the female plant of *Cycas* the stem is really a sympodium, and the cone is thrust aside by a branch which looks like a continuation of the axis. Dichotomy of the roots occurs; this, however, not as a normal development, but due simply to irritation by 'bacterioids'

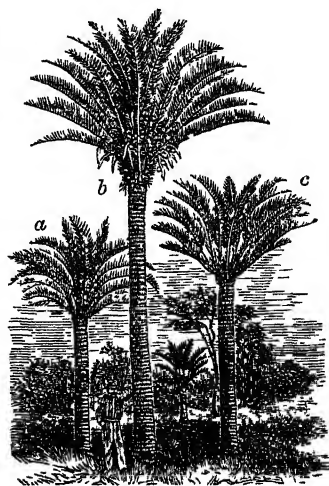

Fig. 1.

a, *Cycas Normanbyana*; b, c, *Cycas metul*

the pinnæ are circinate in bud as in ferns, although the midrib is straight; conversely in *Zamia*, the leaf itself is inrolled, although the pinnæ are straight; in others, however, where both are straight, the pinnæ overlap each other from above downwards, as in the moonwort fern (*Botrychium*). A new crown is developed at intervals of a year, two years, or more. The old leaves droop, lose their pinnæ, and finally drop off, leaving the base attached. The stem is of complex internal structure, but is thickened by permanent cambium. Growth-rings answer to periods of growth and rest. It may bear lateral buds on the axils of old leaves, especially in unhealthy plants; and these may fall off and propagate the plant. Except in the female plant of *Cycas* the stem is really a sympodium, and the cone is thrust aside by a branch which looks like a continuation of the axis. Dichotomy of the roots occurs; this, however, not as a normal development, but due simply to irritation by 'bacterioids'

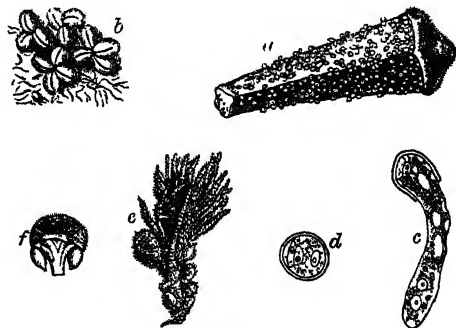

Fig. 2.

a, Stamen of *Cycas circinalis*, under surface; b, group of pollen sacs (Microsporangia); c, pollen-grain of *Ceratozamia*; d, the same germinating; e, carpellary leaf of *Cycas revoluta*, with lower pinnæ reduced and bearing ovules; f, stamen of *Zamia integrifolia*.

and a blue-green alga (*Anabæna*), which commonly invest the root, and inhabit the cortex, causing the root to grow upward and appear above the ground as a coralloid mass (see SYMBIOSIS).

The exceedingly primitive male and female flowers are found on separate plants, and are respectively composed simply of stamens and of carpels, in both cases usually spirally aggregated as cones. The stamens are reduced and undivided leaves bearing on their dorsal surfaces a usually indefinite number of pollen-sacs, so furnishing a perfectly intermediate form between the sporangium-bearing fronds of a fern and the stamens of higher plants. The pollen-grains show a very distinct remnant of the male prothallium. Spermatogenesis is very complex.

Passing to the female flowers, we find the carpels of *Cycas* to be arranged like the foliage-leaves as a crown on the axis, which after flowering resumes vegetative growth, a condition which occurs only as an anomaly or reversion in higher plants (e.g. piliferous roses). The separate carpellary leaves retain more or less distinct traces of vegetative character; thus in *Cycas*, though they are brown, the pinnate form is preserved, two to eight ovules (megasporengia) occupying the place of the lower pinnae. In the other genera, however, the carpels are considerably modified, and only two ovules are ordinarily developed; but the carpellary leaf is always open, and shows no trace of that still more precocious development of its ovules and arrest of its opening altogether, which would give us the ovary of the higher flowering-plants (see OVARY). On ripening, the cone may fall to pieces, liberating the ovules; in the simpler *Cycas* the separate naked seeds become modified and enlarged into large fruit-like bodies, with an outer fleshy and an inner stony wall. The nucellus is crushed into little space by the growth of the endosperm (female gametophyte or prothallium), which contains the straight embryo with its one (Ceratozamia) or two, often unequal (*Cycas*, *Zamia*), cotyledons.

The more vegetative character, both of the flowering axis and of the carpellary leaves, which distinguishes *Cycas* from all the other genera, explains the separation of the order by systematists into Cycadeæ and Zamieæ. Among the latter, *Stangeria* of South-eastern Africa is at once distinguished by its pinnate venation, and *Bowenia* of Queensland by its bipinnate leaves. *Dioon* (Mexico) is characterised by the origin of its ovules on cushion-like modifications of the two parent pinnae, instead of being simply sessile as in the remaining genera, which are merely distinguished by slight differences in the shape of their cone-leaves. The thirty or forty species of *Zamia* range from Florida and Mexico into the Antilles and far into South America. The cones are sometimes nearly as large as the turnip-like underground stem. *Ceratozamia* is Mexican, and the unfortunately named *Microcycas* Cuban, while *Macrozamia* is distributed over Queensland and Western Australia, and *Encephalartos* is characteristically South-east African. But the widest distribution is that of *Cycas* itself. The best-known species, *C. revoluta* of Japan, is widely found both wild and in cultivation in many parts of the Old and New World. *C. circinalis* of the East Indies, *C. media* and *C. Normanbyana* of Australia, *C. Seemant* of the Fijis, may also be mentioned as of importance.

The cycads seem to be descended from ferns through the Palaeozoic Cycadofilicales. Whether some yet unknown members of the Mesozoic Bennettitales were the intermediate ancestors is doubtful. The known fossils of that class stand aside from the direct line.

The stem of many cycads contains an abundant starchy deposit, which is used as food in many countries. It resembles Sago (q.v.) and so has frequently led to the confusion of cycads with the true sago-palms. *C. revoluta* yields a coarse sago in Japan and elsewhere; from *Dioon edule* a kind of

arrowroot is prepared in Mexico, and from *Zamia pumila*, &c., in the Antilles and Florida; while *Encephalartos* is often called Kafir Bread. Owing to their extremely slow growth, cycads are of little commercial value. Moreover, many contain a poison which must be washed out before they are fit for food. *Macrozamia* proved so fatal to cattle in Queensland that the government tried to stamp it out by introducing arsenic into the stem. See Chamberlain, *The Living Cycads* (Chicago, 1919).

**Cyclades.** See ARCHIPELAGO.

**Cyclamen**, a genus of Primulaceæ, including about eight highly variable species, mostly natives of southern Europe. Their thickened and compressed perennial stem half immersed in the ground, their heart-shaped leaves, peculiarly twisted and reflexed corolla-lobes, and spirally reverted fruit-stalks give the genus a peculiar and highly characteristic appearance. They are commonly cultivated on account of the beauty of their flowers, which mostly appear in spring. *C. persicum* is the

*Cyclamen persicum*.

one chiefly grown in our conservatories; *C. europæum*, not uncommon in gardens, flowers in autumn. The turnip-like stem, despite an extreme acidity which long gave it medicinal repute, is largely eaten by swine in southern Europe, especially Sicily; hence the English name of *Sowbread*.

**Cyclanthaceæ**, a characteristic tropical American family of monocotyledons, akin to sciæpines, arums, and palms. Palm-like in general appearance, they are often climbing plants and epiphytes. The inflorescence is a spadix, in which male and female flowers are arranged in various patterns. In *Cyclanthus* large forked leaves rise from the rhizome. The long-stalked spadix is composed of a series of sharp-edged discs or of two spirals, bearing male and female flowers on alternate edges. The female flowers are embedded in the disc, with their ovaries and perianths united all round. The male flowers have no perianth. *Carludovica* is palm-like in form, some species being climbers. The leaves are very large. The young leaves of *C. palmata* are cut into strips, bleached, and made into Panamá hats.

**Cyclanthera**, a tropical American genus of Cucurbitaceæ, in which the union of the stamens found in some other genera of the family is carried to extremity, even the anthers being united to form two ring-shaped loculi running around the column.

**Cycle** (Gr., a 'circle'), in Astronomy and Mathematical Chronology, a period or interval of time in which certain phenomena always recur in the same order. There are two great natural cycles, that of the sun and that of the moon. The solar cycle is a period of twenty-eight Julian years, after which the same days of the week recur on the same days of the year. The lunar or Metonic cycle consists of nineteen years or 235 lunations (see CHRONOLOGY),

after which the successive new moons happen on the same days of the year as during the previous cycle. The number of the year in the cycle of the moon is called the Golden Number (q.v.). The cycle of Indictions (q.v.) is purely arbitrary, its years being fifteen, a conventional number; and the Julian Period, which combines and harmonises all the three others, might be termed the cycle of cycles. The term 'cycle of eclipses' is an instance of the more general use of the word, meaning the period of 223 lunations, within which seventy eclipses recur in the same order and magnitude—viz. twenty-nine of the moon and forty-one of the sun.

**Cycling.** The bicycle is the embodiment of the principle, applied to individual personal locomotion, that weight is more easily wheeled than carried. The credit of its invention can be ascribed to no one in particular, the machine, as it exists to-day, being the result of a long series of inventions and improvements introduced for the most part during the last thirty years of the 19th century. The progenitor of the bicycle was the 'Dandy-horse,' which had a vogue some hundred years ago, for it contained the fundamental principle of the bicycle. It demonstrated the fact that as long as a machine of unstable equilibrium continued in motion it could be balanced and guided by its rider without effort by manipulation of a steering-wheel. The 'Dandy-horse' was what may be called a mechanical freak, and it only assumed a practical form in the 'sixties, when the first material advance was made in its construction by the addition of cranks and pedals to the front wheel for propulsion. The possibilities of the bicycle became recognised about 1870, when its development began in earnest. Wire suspension wheels supplanted those of wood, and metal was employed for the framework. Rubber was first used in strips on the tyres to give silent running, but soon gave place to solid rubber tyres embedded in hollow rims. The size of the front wheel steadily increased to the limits of the rider's reach, while the diameter of the rear wheel diminished to some 20 inches. Meanwhile steel tubes came into use for backbone, forks, and handle-bar; and rollers, superseded later by balls, replaced the plain parallel bearings. Such was the tall, graceful machine of the 'eighties, when, to provide for those who hesitated to trust themselves in so high a seat, the tricycle was developed in a great variety of forms, and enjoyed considerable vogue until the present type of rear-driver appeared, and in course of time became supreme. It was the advent of the pneumatic tyre, for which we are indebted to the late J. B. Dunlop, that expedited the rise into favour of the modern bicycle, as it was better adapted to the small wheels of the 'Safety' than to those of the high machine. Its value became acknowledged about 1890, and it soon came to be regarded as an indispensable accessory to the bicycle. Lever-action mechanisms were introduced from time to time, but the public never took to them, while the small geared front-driver enjoyed some popularity. The two and three speed gears now prevalent constitute the only later inventions worthy of note.

When the bicycle first came to be used on the roads it encountered the bitterest hostility from a section of the public, but chiefly from those who regarded the highway as sacred to the horse, to the exclusion of every form of locomotion to which this useful quadruped objected. Persecution continued for many years, and attempts were made to deprive the bicycle of the use of the highway, but an accident on Muswell Hill in 1878 led to these machines being recognised as 'carriages.' Legislation followed which upheld this view, accorded them rights as such, and provided by laws

for their regulation. Then, horses having become accustomed to them, there was a cessation of the conflicts brought about by the intolerance of their opponents. The animosity they engendered, however, was long-lived, and even now there is a lamentable want of consideration for the bicyclist and of regard for his safety, which is exhibited in the covering of town roads with small flints, which cut his costly tyres to pieces, and the watering of the treacherous tramway lines, practices which go unchecked in spite of the fact that the bicycles in daily use largely outnumber all other carriages.

From the earliest days it was recognised that bicycling was an unrivalled exercise of an independent and vigorous character that appealed to Englishmen; and even on the old high machine many extraordinary rides were accomplished—100 miles a day being quite a common performance, for it is well within the mark to say that a man can ride three times as far as he can walk. The pioneers were very enthusiastic, and vied with one another in making long and exhausting rides. This emulation continued for many years, finally taking the form of road-races and place-to-place records, until the latter became so difficult of attainment that attempts to reduce them were abandoned. One of the most coveted bones of contention was the Land's End to John o' Groat's record. This originated in a holiday jaunt by H. Blackwell and C. Harman, who averaged nearly 70 miles a day from 12th to 24th July 1880, and culminated in the performance of H. Green, who, in 1908, covered the distance—about 870 miles—in 2 days 19 hr. 50 min. Green holds the following road records, which prove him to be the fastest road-rider we have ever had: 50 miles, 2 hr. 1. min. 2 sec.; 100 miles, 4 hr. 36 min. 22 sec.; London to York, 10 hr. 19 min.; London to Liverpool, 11 hr.; 226½ miles in 12 hours, and 394 miles in 24 hours. E. Hale is credited with riding 32,479 miles in the year on the road, or over 100 miles a day, Sundays excepted. The practical character of the high bicycle was shown by Thomas Stevens, who, in 1884, rode across the continent of North America, and, during the next two years, through Europe and Asia back to San Francisco.

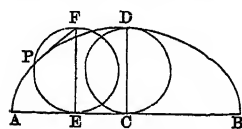

Racing on the track is a form of sport that has been cultivated from the earliest days, and was at its zenith during the period when the graceful and attractive high machine was used by such able exponents of racing as H. L. Cortis, C. E. Liles, G. L. Hillier, and P. Fumivall, and a true sporting spirit pervaded the competitions. Racing subsequently declined in popularity, as far as the public was concerned, from various causes. Partly owing to a broadening of the amateur definition, an undesirable class of riders began to predominate, men who were suborned by the makers of machines and accessories to race for advertising purposes; and the spectacular effect was lost when the high bicycle was supplanted by the rear-driver, which proved the faster machine. Another element in the decadence of racing was the fact that a competitor who rode close behind a rather speedier man throughout a race, and so sheltered himself from the wind, could almost always beat his opponent at the finish. No effective remedy was ever devised to prevent riders from taking this unfair advantage, which robbed racing of much of its interest. On the perfect surface of a race-track almost all the rider's energy is expended in overcoming wind or air-resistance. This is illustrated by the records for one hour of 63 miles 256 yards behind a motor, and 25 miles 1568 yards unaided. Performances in which the aid of 'pacemakers' is employed are therefore illusory, and are of little or no interest from a sporting point of view. The one-mile record of 2 min. 41½ sec. which Cortis made in 1882

has undergone innumerable reductions, and now stands to the credit of V. L. Johnson at 2 min.  $3\frac{1}{2}$  sec., made in 1907.

At first the bicycle promised to be nothing more than a means of obtaining vigorous physical exercise and recreation, but as it developed, its utilitarian character became more manifest. The facility with which distances of 70 or 80 miles a day could be made comfortably has caused it to be used largely for touring purposes, whilst its luggage-carrying capacity is limited in practice only by the difficulty of stowing the various receptacles. Of late years its use has extended largely amongst tradesmen and for other business purposes. In 1896 the bicycle was taken up by the dilettanti, and machines attained their highest prices, £25 being paid for the best makes. Since then severe competition has brought the price down to about £10, and serviceable bicycles are now sold in large numbers at £4 each.

The Cyclists' Touring Club was established in 1878 for the encouragement of road-riding and touring. Its subscription is but five shillings a year, and it has over 20,000 members. It has done much to uphold the rights and privileges of bicyclists on the road, but nothing to what it might have accomplished had the support accorded to it been commensurate with the number of riders in the country, as is the case with the Touring Club de France. It organised a system of uniform hotel tariffs for its members in all the chief towns, and has done a good deal of useful work for bicyclists generally. The National Cyclists' Union is another valuable institution. It derives its support chiefly from the clubs, and devotes its attention principally to the control and organisation of racing. For the past twenty-five years it has fought strenuously and continuously to keep amateur sport passably free from abuses, in addition to which it has done some good work for the general body of riders in upholding their rights on the road. The Roads Improvement Association is another institution in connection with bicycling, whose influence is to be seen in the greatly improved character of our roads. The Stanley Show was an exhibition at which all the novelties in construction were annually displayed. Starting in a small way in 1877, it afterwards enjoyed much prosperity, but was ultimately given up in 1910.

**Cycloid** (Gr., 'circle-like'). If a circle roll along a straight line in its own plane, any point on the circumference describes a curve which is called a cycloid. This is the most interesting of what are called the transcendental curves, both from its geometrical properties and its numerous applications in mechanics. In dynamics, for example, we find that a heavy particle descends from rest from any point in the arc of an inverted cycloid to the lowest point in the same time exactly, from whatever point of the curve it starts. This is sometimes expressed by saying that the cycloid is the *isochronous* (Gr., 'equal-time') curve. The body having

The Cycloid.

reached the lowest point, will, through the impetus received in the fall, ascend the opposite branch of the curve to a height equal to that from which it fell, and it will employ precisely the same time in ascending as it did in descending. It is clear that if a surface could be procured that would be perfectly smooth and hard, the cycloid would thus present a solution of the perpetual motion. The line AB, which is called the base of the cycloid, is equal to the circumference of the generating circle; the length of the curve ADB is four times CD, the

diameter; the evolute of any cycloid is a similar curve of equal length; and the surface between the curve and its base is three times the area of the circle CD. In any position EPF of the generating circle, AE is equal to the arc EP; PE is the normal at P and = half the radius of curvature; PF is the tangent to the curve at P.

**Cycloid-scales.** See SCALES, FISHES.

**Cyclone**, a system of winds blowing inwards towards a centre of low barometric pressure, but deflected into spiral paths in consequence of the earth's rotation. The particles of air retain their moments of inertia about the earth's axis, and therefore in moving into higher or lower latitudes, where their distance from the axis is less or greater, must increase or diminish their velocity. Thus a clockwise movement is found in the southern, a counter-clockwise in the northern, hemisphere. The whole system may itself travel rapidly. An anticyclone is a similar system blowing outwards from a centre of high pressure. See also STORMS.

**Cyclopædia.** See ENCYCLOPÆDIA.

**Cyclopes** fall into three groups. (1) The Homeric Cyclopes, a wild, lawless, and impious race of giants, inhabiting the sea-coasts of Sicily, the most prominent of whom is Polyphemus (q.v.). Although Homer does not directly call them one-eyed, yet he expressly terms Polyphemus such, and the later poets attribute his peculiarity to the rest. (2) The three Cyclopes mentioned by Hesiod: Brontes, Steropes, and Arges, each having one eye in the middle of his forehead; these were sons of Uranus and Gæa, belonged to the race of Titans, and forged thunderbolts for Zeus. Hurlled into Tartarus by their father, but delivered by their mother, they helped Kronos to usurp the government of heaven. Kronos, however, in his turn, threw them back to Tartarus, from which they were again released by Zeus, whose servants they now became. Finally, they were slain by Apollo, because they forged the thunderbolt with which Zeus killed Æsculapius. Later tradition placed their workshop in Mount Etna, or in the volcanoes of Lemnos and Lipari, and made them the slaves of Hephestus. (3) The Cyclopes mentioned by Strabo as a people who had come from Thrace or Lycia to Argolis, and were distinguished for their skill as builders.

**CYCLOPEAN WALLS** is a name given to masonry built of large, irregular stones, closely fitting, but unhewn and uncemented. They were attributed to Strabo's Cyclopes, who were probably mythical, and many of them still exist in Greece (as at Mycenæ and Tiryns), Italy, and elsewhere. It has been customary to suppose that the Cyclopean walls were built by the Pelasgians (q.v.). See CRETE. Peru also has its Cyclopean walls, as at Cuzco.

**Cyclops**, a genus of small fresh-water crustaceans, type of a family (Cyclopidae) in the order Copepoda. They are popularly included under the wide title of 'water-fleas.' Various species are common as active swimmers in fresh-water pools or slow-flowing brooks, and a few forms have been recorded from the sea. Like other copepods, cyclops has an elongated body, without a shell, with four forked thoracic feet and a five-jointed abdomen. The head-region is not distinct from the first ring of the thorax; there is a pear-shaped segmented body and a long abdomen; both pairs of antennæ are long, and in the male the anterior pair form claspers; the mandibular and maxillary palps are degenerate; and a heart is said to be absent. The average length of the commonest species is from 2 to 3 millimetres; the males are generally smaller than the females. A very marked feature, to which the name refers, is the single median eye, usually bright crimson and sparkling like a gem;

and not less noticeable are the two large egg-bags carried by the females. They eat both animal and vegetable matter, and are very prolific. See CRUSTACEA, WATER-FLEA.

**Cyclopteris**, name given to certain leaflets occurring on fern-like fronds which are common Devonian and Carboniferous fossils. Somewhat rounded or wedge-shaped, they have no midrib, the nerves spreading from the point of attachment.

**Cyclorama**. See PANORAMA.

**Cyclosis** (Gr., 'circulation'), the name employed to designate certain movements of the contents of cells in plants. See VEGETABLE PHYSIOLOGY.

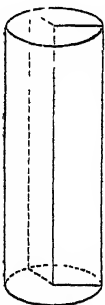

**Cyclostomata** (literally, 'round mouths'), a class of vertebrates often included along with fishes, but separated from them by some fundamental divergences. Hag-fish (Myxine) and Lamprey (Petromyzon) are the two most familiar examples, and are types of the two orders into which the Cyclostomata (or Marsipobranchii) are divided.

**Cydnus**, a river of Cilicia, rising on the south side of the Taurus range, and flowing through a rich and level country, past the city of Tarsus, and a broad lagoon, now choked up with sand, into the sea. Its water was famous for its clearness and coldness, and was supposed to be efficacious against gout and nervous diseases. Alexander nearly lost his life through an illness brought on by bathing in it when overheated.

**Cydonia**. See QUINCE.

**Cygnets**, a young Swan (q.v.).

**Cylinder** (Gr., 'a roller'), a well-known solid whose cross-section at any point of its length gives always the same circle; or, mathematically, a solid generated by the revolution of a rectangle about one of its sides, which line is called the axis of the cylinder. That, the typical cylinder, is frequently called *right*, and if cut by two parallel planes not perpendicular to the axis, the result is an *oblique* cylinder, with elliptical ends or sections. The term has also been generalised to include a solid generated by a line moving parallel to a fixed direction while tracing any fixed closed curve. In all cases the content of the cylinder is found by multiplying the number of square units in the base by the number of linear units in the altitude, which is

the perpendicular distance between the two ends. The area of the convex surface is equal to the product of the circumference of the end, and the length of the generating line. To this must be added the areas of the two ends, to get the whole surface of the cylinder.

**Cyma**. See MOULDING.

**Cymbals** are a pair of thin round metal plates, with a hollow part in the centre, in which a leather strap is fastened for holding in the hand. They are instruments of percussion, which, when struck one against the other, produce a loud harsh sound of no fixed pitch. They are of very ancient origin, and were used by the Greeks in the worship of Cybele. The best cymbals are those made in Turkey and in China. Attempts to discover and imitate the composition of the metal have all failed, the nearest approach to it hitherto discovered being an alloy of 80 parts of copper to 20 of tin. The cymbals sometimes play the same part as the bass drum, and in orchestras they are played by the same performer. One cymbal may be fixed on the drum, the other held in one hand, while the other hand wields a drumstick. Cymbals are, however, essentially military instruments.

**Cymbeline**, an ancient king of Britain in a well-known play of Shakespeare called by his name. By his first wife he had a daughter, Imogen, who married Posthumus Leonatus. His second wife had, by a former husband, a son named Cloten. Shakespeare borrowed the name from the half-historical Cunobelinus in Holinshed's *Chronicle*, of whom several coins are extant.

**Cyme**, a term employed in Botany to designate those forms of inflorescence which are *definite* or *centrifugal*—i.e. in which the main axis ends in a flower, but bears one or more lateral branches which again terminate in flowers, but not before producing secondary branches which continue the same process as far as growth permits. The various forms and varieties of cyme, which are not only of great morphological interest, but frequently also of systematic importance—e.g. Caryophyllaceæ, Labiate, &c., are described under Inflorescence (q.v.).

**Cymry**. See CELTS and WALES.

**Cynanchum**, a genus of Asclepiadaceæ, of which some species have been used medicinally—e.g. *C. monspeliacum* as a violent purgative, the so-called Montpellier Scammony, and *C. vincetori-cum*, formerly in repute as an antidote to other poisons. The Indian *C. extensum* yields fibre, and *C. ovalifolium* of Penang, rubber.

**Cynwulf**, an Old English poet of whom almost nothing is known. He has handed down his name wrapped up in runes in his poems *Christ*, *Juliana*, *Elene*, and *The Fates of the Apostles*. It seems most probable that he was a Northumbrian. Some, following Dietrich, identify him with Cynwulf, the Bishop of Lindisfarne (737–80); Professor A. S. Cook suggests Cynwulf, priest of Dunwich (fl. 803). Cynwulf's principal works may be referred with some degree of confidence to the second half of the 8th or the beginning of the 9th century. He possessed some learning, and was popular with his contemporaries. His poems are aglow with fervid Christian feeling, and show rich imagination and power of language. The chief works ascribed to him with any probability are the *Christ*, a subject borrowed from the old Latin homilies, in which his birth, his ascension, and the judgment are described, the last being particularly effective, but only the second undoubtedly Cynwulf's; *Andreas* and *Elene*, religious epics; *Guthlac* and *Juliana*, versified lives of those saints; and the *Phoenix*; possibly *The Dream of the Rood*. See Kennedy's *The Poems of Cynwulf* (1910; a translation, &c.).

**Cynics**, the name applied to a school of Greek philosophers, who were distinguished mainly for their morose and snarling ethics, and their ostentatious contempt of the ordinary pleasures of life. The name is due either to *Cynosarges*, the place where Antisthenes (q.v.), the founder, taught; or to their dog-like (*kynikos*) contempt for conventional manners. See also DIOGENES. MENIPPUS, &c.

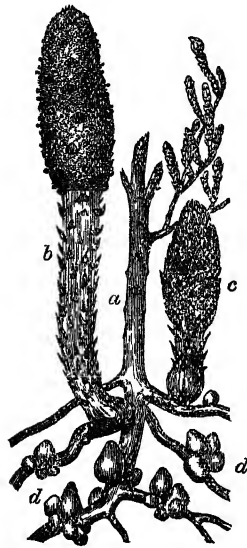

**Cynictis**. See MEERKAT.

**Cynips**. See GALL-FLY.

**Cynodon**, a genus of grasses of which one species, *C. dactylon*, is of peculiarly wide distribution, not only ranging from its British habitat on the sandy shores of Cornwall to fringe those of North America and the West Indies, where it is known as Bermuda grass, but also forming (on account of its great power of resisting drought) the most important fodder and pasture grass of India, where it is known as *Dhob*, *Doorba*, &c. Its creeping roots, and those of its congener, *C. lineare*, have medicinal virtues, and are sometimes used as a substitute for sarsaparilla.

**Cynomorium**, a genus of flowering plants of the order Cynomoriaceæ, consisting of one species,

*C. coccineum*, a plant of a strange fungus-like appearance, found in Malta and other Mediterranean lands. It was long known as *Fungus Melitensis*, and enjoyed the highest reputation as a styptic, besides being used as an astringent in dysentery and other maladies. These uses, however, depended on the doctrine of signatures alone, its scarlet colour and blood-like juice being interpreted as providential indications of its curative destination for all injuries or diseases accompanied by bleeding. So high a value was set upon this plant, that the knights of Malta took it under their particular care as one of their choicest possessions; it was carefully gathered and deposited in a government office, from which the grand-master sent it to friendly sovereigns, and to the hospitals of the island. *C. coccineum* is a parasite on the roots of shrubs, to which it attaches

*Cynomorium coccineum*, growing upon the roots of (a) its phanerogamous host; b, c, d, different stages of development.

itself by suckers; see PARASITIC PLANTS. The Cynomoriaceæ are allied to the Balanophoraceæ.

**Cynomorpha** (literally, 'dog-shaped'), the lower division of Old-World or Catarrhine monkeys. Baboon (*Cynocephalus*) and Magot (*Macacus*) are good examples. See MONKEYS.

**Cynoscephalæ** ('dog's heads'), two hills near Scotussa, in Thessaly, where Flaminius defeated Philip of Macedon, 197 B.C.

**Cynosure** (Gr. *kynosoura*, literally, 'the tail of the dog'), the Greek name for the constellation of the Little Bear, which contains the pole star, by which the Phœnician mariners steered their course, while the Greeks steered by the Great Bear. The name is metaphorically applied to anything that attracts attention, or to which all eyes are turned. Its use, with this meaning in reference to a lady, in Milton's classic poems *L'Allegro* and *Comus*, will be remembered. In the Greek mythology, Callisto, daughter of Lycaon, king of Arcadia, was changed into the Greater Bear (called also *Helice*), and her son, Arcas, into the Lesser (called also *Cynosura*).—The Dog's-tail Grass is called *Cynosurus*.

**Cyperaceæ**, the order of reeds and sedges, are nearly akin to grasses, but easily distinguished by their solid, unjointed, generally triangular stems, undivided leaf-sheaths, and absence of paleæ. There are about 2500 species, widely distributed throughout all climates, but more especially in temperate and cold regions, and in marshy soils, of which they often take almost entire possession. Dry and rough in texture, they furnish only the very poorest constituent of fodder or hay, nor with few exceptions (see BULRUSH, CYPERUS, PAPYRUS, CAREX, REED, COTTON-GRASS) have they any other use.

**Cyperus**, a large genus of Cyperaceæ, chiefly tropical. The tubers or root-stocks of some species are edible, notably *C. esculentus*, cultivated in southern Europe for its *amandes de terre*. *C. longus* and others are used in medicine and perfumery. *C. textilis* of South Africa yields fibre. In America,

*C. hydra*, a tuberous species, is an exceedingly troublesome weed in cultivated lands, such as cotton-fields. See PAPYRUS.

**Cy-près**, which, roughly translated, means 'as near as possible,' is applied to a well-known doctrine in the law of charitable trusts in England. This doctrine is to the effect that where a trust mentions a general purpose to which money is to be applied—e.g. higher education, and also some particular method—e.g. payment to an institution which ceases to exist, the court will direct the application of the money in some other particular method, as near as possible to the one mentioned, and consistent with the general purpose. The doctrine is closely connected with another—viz. that where only a general charitable intention is expressed—e.g. relief of the poor, the court will devise some particular scheme, and will not hold the trust void for uncertainty. These doctrines also exist in Scots law, though not under the name of cy-près. The expression is also applied to a principle on which the court acts, so as to avoid illegality in settlements of property. In the United States it is held that the equity courts cannot make valid charities which are uncertain, but where charitable trusts have once been set agoing, they will prevent the trust from being defeated by change of circumstances.

**Cypress** (*Cupressus*), a genus of evergreen trees or shrubs of the natural order Conifere, with small appressed, imbricated leaves and globular cones, the peltate woody scales of which bear numerous hard winged seeds. The cypresses are indigenous to southern Europe, North America, Mexico, Guatemala, Asia Minor, India, and China. One of the most widespread species is the Common Cypress (*C. sempervirens*), a native of Greece, Asia Minor, Persia, and Afghanistan, which was introduced into Britain in 1548, and is now acclimatised throughout southern Europe. In southern France and in Italy it is now one of the most frequent and characteristic trees, especially near the coast. One variety has spreading or drooping branches, while another is of a fastigate habit; and this latter is the more

Branch of Cypress.

frequent. Being of sombre aspect like our yew, it has been largely planted in churchyards and cemeteries. The ancient Greeks and Romans employed cypress twigs and branches as symbols of mourning, and planted cypress-trees around tombs. The vast Turkish cemeteries, of which European and American cemeteries may be regarded as imitations, are thickly planted with the fastigate variety, and are often growing into sombre forests. The wood of the cypress is yellow or reddish, and has a pleasant smell. It is very hard, compact, and durable; the ancients reckoned it indestructible; and the resin which it contains gives it the property of resisting for a long time the action of water. It is not liable to the attacks of insects, and being also of beautiful

colour and easy polish, was formerly much esteemed for the finest kinds of work in wood, even Cupid's arrows being traditionally made of cypress-wood. Some believe that the cypress is the true cedar-wood of Scripture, and it has also been identified by commentators as the *gopher wood* of Noah's ark. In any case, cypress and cedar have been prized for their timber in the East from the earliest times. The doors of St Peter's at Rome, made of cypress, lasted from the time of Constantine the Great to that of Pope Eugene IV., above 1100 years, and were perfectly sound when at last removed, that brazen ones might be substituted. Medicinal virtues were formerly ascribed to the wood and seeds of the cypress, and Oriental physicians have long been wont to send patients suffering from chest-diseases to breathe the air of cypress-woods, thus curiously anticipating the Western practitioner. The resin has had medicinal repute from classic times, while the Turks still use also the fruit and bark. The ethereal oil of cypress-wood was used by the ancients for embalming, and the coffins of mummies were made of the wood.

Three kinds of cypress are now commonly grown in Britain in ornamental grounds, and sometimes even in woodlands, viz. the Monterey or Large-coned Cypress (*C. macrocarpa*), introduced from California into Britain in 1838; the Lawson's Cypress (*C. Lawsoniana*), also from California, introduced in 1854; and the Nootka Sound or Alaska Cypress (*C. nothaensis*), introduced from the north-west coast of North America in 1850. These two last have been classed by some botanists as a separate genus (*Chamaecyparis*), to which also the Japan or Obtuse-leaved Cypress (*C. obtusa*) belongs. They grow well in the milder and damper parts of Britain, and yield good timber. They can all be easily raised from slips or cuttings, but are far better raised from seed if desired to grow into large trees. There are numerous gardener's varieties, which are propagated by cuttings.

**Cyprian**, St. Thascius Cæcilius Cyprianus, one of the most illustrious Fathers of the church, was born about 200 A.D., probably at Carthage, of heathen parents. After being a teacher of rhetoric at Carthage, he became a Christian, and was baptised probably in 245 or 246. Immediately afterwards he gave to the poor the greater part of his considerable fortune, and devoted himself assiduously to the study of Scripture and the writings of the church's teachers, especially Tertullian. After being successively a deacon and presbyter, he was made a bishop in 248. His zealous efforts for the restoration of strict discipline soon brought him a host of enemies. In the Decian persecution, which at Carthage was especially severe, the heathen people cried incessantly '*Cyprianum ad leonem!*' but Cyprian sought safety in flight, in his retirement still caring for his flock with the help of two *vicars*, and distributing large sums of money among the poor. He returned to Carthage in 251, and the rest of his life was a constant struggle to hold the balance between the two extreme parties—the adherents of Felicissimus and Privatus on the one hand, who favoured laxity in the treatment of the *Lapsed* (q.v.), and those who would exercise the utmost severity, such as the followers of Novatianus, on the other. Cyprian was excommunicated by the Roman bishop Stephanus for his opposition to the Roman view of the validity of heretic baptism. He rejected this doctrine as making the sacrament merely mechanical, and laid stress on the personal piety of the priesthood and their special authority for its administration, asserting that baptism could only be a reality when accompanied 'with the full and entire faith both of the giver and receiver. At a synod at Carthage in 256,

he maintained that the Roman bishop, spite of the primacy of Peter, could not claim a judicial authority over other bishops. His principle, that 'a priest of God, holding the gospel and keeping the commandments of Christ, may be put to death, but cannot be overcome,' Cyprian himself illustrated, on the 14th September 258, when he suffered martyrdom under the Emperor Valerian.

His character and conduct have been very variously judged. Both in his own and later times he has been accused of cowardice and pride. His zeal, fidelity, and self-denial were undeniable, and his courageous martyrdom frees him from the reproach of cowardice. His writings are all directed to practical ends. The earliest complete editions of his works are by Erasmus (Basel, 1520), Pamelius (Antwerp, 1568), and Bishop Fell (Oxford, 1682); and the best is that of Hartel (3 vols. Vienna, 1868-71). They consist of a collection of *Epistles*, and a series of treatises, which are themselves pastoral epistles of a bishop to his flock (see the translation by Wallis, 2 vols. 1869). His best-known work, *De Catholica Ecclesie Unitate*, laid the foundation of the hierarchical conception of the church. Cyprian holds that the unity of the church is founded upon the episcopate, not of Rome, but of the universal Church. In the Church alone can salvation be obtained ('he cannot have God for his Father, who has not the church as his mother'). See the Lives by Poole (Oxford, 1840), Peters (Ratisbon, 1877), and Fechtrop (Munich, 1878); and Archbishop Benson's *Cyprian: his Life, his Times, his Work* (1897).

**Cyprinidæ** ('carps'), a large family of fresh-water bony fishes in the order Physostomi, with open swim-bladders. Babel, Bream, Carp, Chub, Dace, Gold-fish, Gudgeon, Minnow, Roach, Tench, are familiar examples. They are distinguished from their neighbours by their small toothless mouths, naked head, usually scaled body, and by the absence of the adipose fin. The family includes about two hundred genera and a thousand species. They are widely distributed, most abundant in north temperate regions, absent from Australia and South America. They are voracious, very fertile, and frequently hibernates. See CARP, &c.

**Cyprinodontidæ** ('toothed carps'), a family of small bony fishes in the order Physostomi, with open swim-bladders. They are allied to the pike. The mouth bears teeth, the head and body are scaled, and there are never barbules. The family includes twenty genera and about two hundred species, widely distributed in the warm and tropical zones, both fresh-water and marine. They are in most cases ovo-viviparous, and the males are generally smaller than the females. The majority are carnivorous, but several forms are known as mud-eaters. Cyprinodon, Fundulus, Anableps (q.v.), and Pécilia are the more important genera.

**Cypripedium**, or SLIPPER-ORCHIS. See ORCHIDS.

**Cypris**, a very common small fresh-water crustacean, type of a family (Cypridæ) in the order Ostracoda. Like other ostracods, this small 'Water-flea' (q.v.) has an unsegmented body, seven pairs of appendages, a rudimentary abdomen, and a bivalve mollusc-like shell inclosing all. The shell of cypris is dainty and elastic; the posterior antennæ bear a long tuft of bristles on their second joint; the second pair of maxillæ have a small gill-appendage; the posterior limbs are very irregular. Various species of cypris are readily found in fresh-water pools, in which they swim very actively; the largest form (*C. pubera*) measures 2.7 millimetres in length. The reproductive relations are of some general interest. Some species—e.g. *C.*

*fusca* and *C. pubera*, reproduce parthenogenically in summer and autumn, the males being rare and transient; while in others—e.g. *C. ovum*, the males are found throughout the year, and parthenogenesis seems not to occur. The eggs are usually laid in masses on stones and water-plants; in *C. pubera* the egg remains as such throughout the winter. The males are remarkable for a peculiarly long and complex syringe-like modification of the reproductive duct. The adults are said to be able to survive desiccation, and this is certainly true of the eggs. Some species are very abundant as fossils in fresh-water strata—e.g. *C. waldensis*, in the English Wealden. See CRUSTACEA.

**Cyprus** (Gr. *Kypros*, Turk. *Gibris*, Fr. *Chypre*, Ital. *Cipro*) is situated in the north-east of the eastern basin of the Mediterranean, S. of Asia Minor, and W. of Syria, between 34° 30' and 35° 41' N. lat., and 32° 15' and 34° 36' E. long. The distance from Cape St Andreas, the north-easternmost point of the island, to the mainland of Syria near Latakia is about 52 geographical miles, while Cape Kormakiti on the north of the island is only 35 miles from Cape Anamúr in Cilicia. The familiar shape of the island was likened by the ancient Greeks to that of a deer's skin, of which the long and narrow peninsula of Carpas represented the tail. The extreme length is about 140 miles, of which 40 consist of this Carpas peninsula; the extreme breadth is 60 miles; and the area is 3584 sq. m., or a little larger than Norfolk and Suffolk together; it is the largest island of the Mediterranean. There are two principal ranges of mountains, which form the most remarkable natural feature of the country. The northern range, called the Kyrenia Mountains, extends from Cape St Andreas, at the extreme east of the island, almost as far as Cape Kormakiti, some 20 miles to the west of Kyrenia. The highest mountain of this range is Akromandra (3343 feet), lying to the north of Larnaca tes Lapethou; Buffavento (3135 feet), St Hilarion (3340), and Pentadaktylon (2405), are situated almost immediately north of Nicosia, and appear, owing to the extreme clearness of the atmosphere, to rise almost from the outskirts of the town, from which they are distant fully 12 miles. To the south of this range, and extending from Salamis to Morphu Bay, is the great Mesaorian plain, once famous for its crops of cereals. It produces good yields still, but suffers much from drought. In 1901 government irrigation works were set in operation, but these have hardly proved successful, and consideration continues to be given to the question of their extension and improvement. The western range occupies the greater part of the western and south-western districts of Cyprus, and extends to the east as far as the isolated peak of Santa Croce or Stavrovouni (2260 feet), only 12 miles to the west of Larnaca. The highest mountain of this range is Mount Troödos (6406 feet), of which one of the peaks bears the classic name of Olympus.

On the south-eastern slopes of Troödos, under gigantic pine-trees, are the summer quarters of the garrison and of the government officials. Cyprus had for long no good harbours; the seaports of Larnaca and Limassol are open roadsteads, unprotected against all but northerly winds, with such shallow water that steamers are obliged to anchor at a considerable distance from the shore. Moreover, a dangerous surf is raised in stormy weather, which renders landing difficult. At Kyrenia there is a little harbour fit only for small craft, and poorly protected in northerly winds; there is a small harbour also at Paphos, and in days gone by there was a harbour at Salamis. Famagusta is the only harbour suitable for large ships, and that only since its restoration

in 1903-6. It has often been proposed to construct a great commercial and naval harbour there, but at present the town is little more than a collection of ruins encircled by fortifications, though it is in process of being rebuilt and opened out.

The rivers flow only after heavy rain or the melting of the snow in the hills, but then overflowing their banks they flood the surrounding country with rich alluvial earth; none are navigable. Paralimne, near Famagusta, was formerly the only lake of importance, but it has now been drained for cultivation. It was noteworthy chiefly because, though entirely dry in summer, it abounded in fish during the winter, a phenomenon which was never explained, though it certainly could not be called in question. The chief towns are Nicosia (the capital), Larnaca, Limassol, Famagusta, Ktema, and Kyrenia, each giving its name to one of the six administrative districts of the island. Until 1885, when the map of the trigonometrical survey of the island appeared, the topography of Cyprus was by no means accurately known.

A census taken by order of government in 1921 showed the population to be 310,715, of whom more than four-fifths were Christians of the Independent Cypriote Church, a branch of the Orthodox Eastern Church; the remainder were Mohammedans. The Greek-Christian inhabitants speak as their mother-tongue a form of the Romaic or modern Greek; the Moslems, Turkish. The Cypriote Greek dialect is a poor as well as a corrupt idiom, neither expressive nor harmonious; but the language of the Cypriote Moslems is remarkably pure.

**History.**—Cyprus, rich in copper, had already passed from a Neolithic to a Copper and a Bronze Age, and had adopted the late Minoan culture (see CRETE) before its conquest by Thothmes III. of Egypt. Later it was inhabited by Phoenicians and Greeks. The Cyprian or Paphian goddess, answering to the Phoenician Astarte or Ashtaroth, was worshipped by the Greeks as Aphrodite. A syllabary, perhaps of Ægean or Hittite affinities, preceded the Greek alphabet. Early in the 6th century B.C. Cyprus was conquered by the Egyptian king Amasis; and a little later by Cambyses, who annexed it to Persia, 525 B.C. After the battle of Issus, Cyprus became a part of the Macedonian empire, but on the death of Alexander it passed into the possession of the Egyptian Ptolemy. In 58 B.C. Cyprus became a Roman province, and was administered by Cato the Younger and Cicero. The Cypriotes were one of the first Gentile peoples to embrace Christianity, and Cyprus was visited not only by St Paul but by many saints of the early church. At the division of the empire Cyprus naturally passed into the hands of the Eastern or Byzantine emperors, to whom it continued subject for over seven hundred years. In consequence of the alleged discovery by a shepherd of the original copy of the gospel of St Matthew near Salamis, in the 4th century, Cyprus was constituted by the empire a separate autonomous church, and to the archbishop was accorded the privilege, enjoyed only by the emperor himself, of signing his name in red ink, a privilege which has been uninterruptedly exercised to the present day. In 646 Cyprus was taken by the Saracens, under Othman, and again in 802 by Haroun al Rashid; but on each occasion it remained but a very short period under the sway of the Moslem. In 1195 Richard I., on his way to Syria for the third crusade, took the island from Isaac Comnenus, the representative or duke of the eastern emperor, and sold it to Guy de Lusignan, king of Jerusalem, in whose family the sovereignty of the island remained until 1487, when it passed under the dominion of the republic of Venice. In 1570 the Turks under Selim II. invaded Cyprus, and after long sieges and terrible massacres at

Famagusta and Nicosia, took possession of the country and ruled it for three hundred years. On the 10th July 1878 Cyprus was occupied by the British, under the provision of the celebrated Turkish Convention, by the terms of which the island was to be occupied by Great Britain until Batum, Kars, and Erzerum should be restored to Turkey by Russia, England paying £92,800 a year to the Porte as quit-rent. By a subsequent arrangement this 'tribute' was paid by Cyprus to England, and England paid one-half to the bondholders of the British-guaranteed Turkish Loan of 1855. In 1880 the administration of Cyprus was transferred from the Foreign to the Colonial Office, and in 1882 a constitution, with a partly elected council, was granted to Cyprus. During the Great War the convention was annulled on the outbreak of hostilities between Turkey and the United Kingdom in November 1914, when the latter annexed Cyprus. Cession to Greece was sought by the islanders and by the Greeks; but annexation by Britain was confirmed on the conclusion of peace.

Although just as under the convention the English still maintain the Mohammedan religious tribunals, or *sheri* courts, an admirable judicial system has been introduced, and English barrister-judges preside over courts which are highly appreciated by the people. The fiscal system, however, is well-nigh unreformed, and is most unsatisfactory, as is the system of land tenures. The Eastern Telegraph Company have stations throughout the island, the cable connecting with Alexandria and Syria. Postal communication with England is slow and unsatisfactory; within the island it is efficient. The police, about 900 (mostly Moslems) horse and foot, under English officers, is an admirable force. The Cypriotes are peaceable, orderly, and easily ruled. There are three gymnasiums, eleven high schools, at least 500 Christian elementary schools, and over 240 Moslem schools.

Cyprus produces wheat, barley, vegetables (especially potatoes), cheese, cotton, silk, flax, carobs, madder, wool, grapes, oranges, pomegranates, linseed, aniseed, sponges, gum-mastic, spirits, and wine. Tobacco-growing, which had greatly declined, has within recent years again become an important industry. Carobs, or locust-beans, are perhaps the principal export; others of importance are potatoes, raisins, wine, tobacco. Cattle, mules, donkeys, sheep, and poultry are also exported. Oats and wheat are grown in large quantities, mostly for home consumption. Barley is used as grain for horses and cattle, and as spring fodder, in a green state, in place of grass, of which none grows in the island. Wool and silk (cocoons) are exported, but a good deal of both is spun and woven in the country. The total value of all exports in 1906-21 varied from £484,000 to £918,000.

Cyprus was once celebrated for its copper-mines, which were worked by the Phoenicians and Romans; indeed, the word copper is derived from the name of the island. The industry has recently been revived on a considerable scale. Asbestos and marble are found, and much terra-umbra is burnt. Gypsum is mined, and plaster of Paris is manufactured at Larnaca in large quantities and exported chiefly to Alexandria. Salt was produced, under the Turks, to the value of £40,000 a year, by evaporation at the salines, near Larnaca, whence that town is sometimes called Salinas. At present, owing to prohibitive duties in the neighbouring countries, no salt is exported, and only a very small amount for island consumption is made by the British authorities. Cyprus imports (to the value of from £290,000 to £1,450,000) wheat-flour, barley, olive-oil, sugar, textile fabrics, iron and copper goods, rice, dried fish, coal, timber, cotton-yarn and piece-goods, tobacco, petroleum, leather, &c.

The annual revenue is about £660,000, of which nearly an eighth is produced by excise, and about a fifth by customs; while of the remainder, part is derived from land-tax, but by much the greater portion from the tithe on produce, an oppressive, antiquated, and expensive form of taxation. The tithe on grapes was abolished in 1884. The expenditure in the island amounts now to about £680,000. Since 1910 a fixed annual sum of £50,000 has been paid from imperial funds as a grant-in-aid of Cyprus revenues. The climate of Cyprus has been unduly vilified. Except on the seashore in summer, it is healthy, dry, and pleasant, and the death-rate is low. In the plains the summer heat is intense and exhausting, but the bracing cold of the winter months is sufficient to repair waste and restore vital energy. Previous to the British occupation malaria was prevalent, but prophylactic measures introduced since then by the government have done much to minimise the extent of the disease, which is now almost confined to the native population. Ophthalmia and intermittent fever of a mild type are the commonest forms of disease. Throat, chest, and lung complaints are exceedingly rare, but leprosy is not uncommon. The people are healthy and well grown; the men, as a rule, handsome, the women rarely so.

The *flora* and *fauna* are with few exceptions the same as those of the neighbouring coasts of Syria and Asia Minor. Among wild animals the moufflon or Cyprian sheep is the most interesting, but is becoming very scarce. Mules of peculiar excellence are bred in Cyprus, and command large prices. Goats are amongst the pests of the island. The forests (for which Cyprus was once famous) have well-nigh disappeared, and the climate and fertility of the country have greatly suffered in consequence. Under government protection, however, recovery has begun, though, notwithstanding the law of 1913, goats still do much damage by biting off the tops of the young shoots as fast as they appear. A still greater scourge earlier commanded the attention of the authorities, and the Locusts (q.v.) are now almost exterminated. The work of destruction has been thoroughly as well as economically performed (especially 1880-84), on the 'screen and pit' system invented by Richard Mattei, of Cyprus.

Since the English occupation the prosperity of the island has greatly increased. Roads have been improved, and an efficient system of motor transport introduced; the breeding of horses, mules, and other live-stock greatly encouraged; and under the Colonial Loans Act of 1899, £314,000 has been advanced by the home government for general improvements, irrigation, &c. Silk-culture has been revived. There are 240 miles of telegraph lines. There is a railway from Famagusta to Nicosia, Morphu, and Evrykhon.

Mallock (1889 and 1916), Mrs Lewis (1894), Ohnefalsch-Richter (1894, 1914; and with Myres, 1899), Luke and Jardine (1920), Orr (1918), Luke (1919); Macheras, *Chronique de Chypre* (Paris, 1891), and Cobham, *Excerpta Cypria* (1908), and *Bibliography* (1908); vol. iii. of Perrot and Chipiez's *History of Ancient Art* (trans. 1885); Jeffery (for ancient monuments, 1910); church histories by Duckworth (1900) and Hackett (1901).

**Cyrano.** See BERGERAC.

**Cyrenaica**, the name of the district in northern Africa whose capital was Cyrene (q.v.). In its widest limits it stretched from the borders of Carthage to the Chersonesus Magna or northern headland of the Gulf of Platea (Gulf of Bomba). The productions of Cyrenaica mentioned by ancient writers are corn, oil, wine, honey, fruits of all kinds, cucumbers, truffles, cabbage; flowers yielding the richest perfumes; a rare plant called

*silphium* (not identified), from which was obtained a famous medicinal gum-resin; and its horses. The first settlements in Cyrenaica were made by a Spartan colony in 631 B.C. The earliest cities were Teuchira and Hesperis, then Barca, a colony from Cyrene; and these, with Cyrene itself, and its port Apollonia, formed the original Libyan *Pentapolis*; subsequently, Hesperis became Berenice; Teuchira, Arsinoë; while Barca was eclipsed by its port, Ptolemais. Cyrenaica at length became Roman, and was called Libya Superior. In the 7th century it was conquered by the Arabs, in the 16th by the Turks, but was ceded by them as part of Tripoli (q.v.) to Italy in 1912, and now forms one of the two independent administrative and military districts of Italian Libya.

**Cyrené**, the capital of Cyrenaica (q.v.), founded in 631 B.C. by a colony of Spartans under Battus, whose dynasty ruled for nearly two centuries, and was replaced by a republic, which was far from prosperous, until the advent of Roman rule. Cyrene carried on a great commerce with Greece and Egypt, and to a less extent with Carthage. Its extensive ruins, the scene of important archaeological discoveries, still attest its former magnificence. It is repeatedly mentioned in the New Testament. Here were born the philosophers Aistippus (q.v.), Anniceris, and Carneades, the poet Callimachus, the astronomer Eratosthenes, and the Christian rhetorician and bishop, Synesius.

**Cyrenius**, a Grecised form of Publius Sulpicius Quirinus, named in Luke ii. as governor of Syria. He received his appointment as governor in 6 A.D., but the difficulty in harmonising this with Luke is got over by admitting that he had been governor also at an earlier date—according to Zumpt, from 4 B.C. to 1 B.C.

**Cyril and Methodius**, apostles of the Slavs, were brothers, and natives of Thessalonica. Cyril was the name adopted as a monk by Constantine, born in 827. He had been a disciple of Photius, and for his learning was surnamed 'the philosopher.' The Khazars, a Tatar people who inhabited the country from the north-east of the Black Sea to the lower Volga, having about the year 860 asked the Emperor Michael III. to send them Christian missionaries, Cyril was sent in answer to their appeal, and made many converts. The Bulgarians of Thrace and Moesia were evangelised by Methodius, who baptised their king Bogoris in 861. At the request of Ratislav, Duke of Moravia, the brothers then turned to the countries on the March and Danube. They prepared a Slav translation of the Scriptures and chief liturgical books (which became the foundation of the literature of the Slavs), and by their services in the mother-tongue won the hearts of the people from the Roman missionaries. The two brothers were summoned to Rome to explain their conduct, and Cyril died there in 869. Methodius, who in the same year was consecrated at Rome Bishop of the Moravians, completed the evangelisation of the Slavs. Called to Rome a second time in 879 to justify his celebration of the mass in the native tongue, he succeeded in gaining the approval of Pope John VIII., returned to his diocese in 880, and (according to the most probable account) died at Hradisch on the March, 6th April 885. Bohemia and Moravia celebrated the millenary festival of their two apostles on the 5th July 1863. Both brothers are recognised as saints by the Roman Catholic Church, after having been condemned as Arians by several popes (including Gregory VII.). Their festival falls in the Roman Catholic Church on the 9th of March, in the Greek Church on the 11th of May. The Cyrillic alphabet, modified out of the Greek by Cyril, superseded the

more ancient Slavonic alphabet over a wide area. The history of Cyril and Methodius is still very obscure. The sources are collected by Schafarik in vol. ii. of his *Slavische Alterthümer*, and more completely by Ginzler in his *Cyril und Method* (1857). See also works by Dummmler and Miklosich (1870), Bonwelch (1885), Goetz (1897); Maclean's *Conversion of the Slavs* (1879); and the article in Herzog-Hauck.

**Cyril of Alexandria**, St., one of the Fathers of the church, was born at Alexandria, and brought up under the care of his uncle Theophilus, whom, after some years spent as a monk in the Nitrian desert, he succeeded as patriarch of Alexandria in 412. Cyril forthwith closed the churches of the Novatians, and in 415 expelled the Jews from the city. With the shameful murder of Hypatia (q.v.) he was at least indirectly connected. The latter part of his life was spent in his relentless persecution of Nestorius (q.v.), against whom, in the name of a synod held at Alexandria in 430, he hurled twelve anathemas for his refusal to apply to the Virgin Mary the epithet *Theotokos* ('Mother of God'). The œcumenical council of Ephesus in 431 condemned Nestorius, with his doctrine of the two natures in Christ. After this, John of Antioch, with his adherents (numbering from 30 to 40 bishops), who had arrived at Ephesus too late to take part in the discussion, constituted a synod of their own, which condemned Cyril. The emperor confirmed both of these depositions, but Cyril, notwithstanding, kept his patriarchate till his death in 444. On hearing of his death, Theodoret wrote, 'Envy is dead, and heresy is buried with her.' Among the extant works of Cyril are a defence of Christianity, in 10 books, written against the Emperor Julian in 433; a series of homilies and dogmatic treatises on the Trinity, the Incarnation, and on the Worship of God in spirit and in truth (17 books, written against the Anthropomorphites).

The standard edition of his works is that of Aubert (7 vols. Paris, 1638; closely followed in Migne's reprint). See Neander's *Church History*, Newman's *Historical Sketches* (vol. ii.), Kingsley's *Hypatia*, Hefele's *History of the Councils* (vol. ii.), Kopallik's *Cyril von Alexandria* (1881), Largent's *St Cyrille d'Alexandrie* (1892), and the article in Herzog-Hauck (1896-1909).

**Cyril of Jerusalem**, St., was born probably about 315, but his descent and birthplace are unknown. About 334 he was ordained a deacon, and about 345 a presbyter. During the Arian controversies he endeavoured to maintain a neutral attitude, and in 351 was ordained Bishop of Jerusalem by Acacius, Bishop of Cæsarea, who was an Arian. Cyril having repeatedly disregarded citations by Acacius, his metropolitan, was deposed by him in 358, and by a synod at Constantinople in 360; but on the accession of Julian in 361 he returned to his flock, which he ruled in peace till 367, when, by order of Valens, he was again expelled. He returned to Jerusalem on the death of Valens in 378, took part in the second œcumenical council at Constantinople, and died on the 18th (according to other accounts, on the 11th or 20th) March 386. The genuine writings of Cyril are his *Katecheseis* (or instructions to catechumens), eighteen of which are addressed to candidates for baptism, and five to the newly baptised. They are not in the form of question and answer, but are connected lectures, written in a style of great simplicity and clearness, and making constant reference to Scripture. The articles of the creed (called by Cyril *Pistis*, or the 'Faith') on which the teaching is based can be gathered with tolerable certainty from the last thirteen of the first series of the *Katecheseis*, and are distinguished from those of the Nicene Creed by the avoidance of its distinctive word *Homousios* ('of the same substance'). The best editions are

by Tontée (1720, 1844) and by Reischl and Rupp (1845-60). There is a translation by Dean Church in the *Oxford Library of the Fathers*, and by Gifford in *The Nicene and Post-Nicene Fathers*. See work by Delacroix (1865), and Herzog-Hauck (1896-1909).

**CYRUS THE GREAT** (*Kurus*, perhaps from *kur*, 'a mountain'), the founder of the Persian empire. He was the fourth in a line of kings of Anzan or Susiana (called by the Hebrews *Elam*) who formed a branch of the royal dynasty of the Achæmenides. According to Herodotus, Cyrus was the son of Mandane, daughter of Astyages, king of Media, and the Persian Cambyses. Moved by superstitious fears, Astyages attempted to destroy him in his infancy, but the child was saved by a herdsman, who brought him up as his own son. Being recognised in his boyhood by Astyages, he was sent to his parents in Persia. Cyrus in course of time rose against Astyages and conquered him. This narrative and the greatly varying accounts of Xenophon, Ctesias, Nicolaus of Damascus, Diodorus, and Trogus Pompeius, formerly regarded as the authorities for the life of Cyrus, have been superseded by the evidence of monuments discovered in modern times. Thus a new light has been thrown on his history by the discovery of his own cuneiform records on a clay tablet and cylinder which were brought from Babylon to England. Cyrus was the son of Cambyses I., grandson of Cyrus I., and great-grandson of Teispes, conqueror of Elam, who was also the great-grandfather of Hystaspes, the rather of Darius (q.v.). From the tablet-inscription we learn that in the sixth year of Nabonidus, king of Babylon (549 B.C.), Cyrus, 'king of Elam,' conquered Astyages, king of Media, made him a prisoner, and took his capital, Ecbatana. By the year 546 he had become 'king of Persia.' Year after year was idly spent by Nabonidus at Tema, a suburb of Babylon, while his son (doubtless Belshazzar) was with his army in Akkad (Northern Babylonia). In 539 Cyrus, favoured by a revolt of the tribes on 'the Lower Sea,' or Persian Gulf, advanced on Babylon from the south-east, and, after giving battle to the army of Akkad, took Sippara (Sépharvaim) and Babylon itself 'without fighting.' The account of the siege of Babylon by Cyrus recorded by Herodotus must therefore be erroneous. The Greek historian seems to have transferred to the reign of Cyrus events which took place in the reign of Darius. On the eighth day after Cyrus entered Babylon in person, he appointed Gobryas its governor, and that very day Nabonidus died. Nabonidus in his distress had brought the images of many local gods to Babylon, so as to protect it from the invader; and the cylinder-inscription shows very clearly that Cyrus was a polytheist and an idolater, for he there says, 'the gods dwelling within them left their shrines in anger when [Nabonidus] brought them to Babylon,' and, after telling how he had restored them all to their sanctuaries, prays them to intercede before Nebo and 'Merodach my lord,' for himself and Cambyses his son. Cyrus at once began a policy of religious conciliation. The nations who had been carried into captivity in Babylon along with the Jews were restored to their native countries, and allowed to take their gods with them. The empire of Lydia had fallen before the army of Cyrus eight years before (in 546), and after the conquest of Babylonia he was master of all Asia from the Mediterranean to the Hindu Kush. The conqueror's hold over Asia Minor and Syria was much strengthened by his friendly relations with the Phœnicians and also with the Jews, who received the news of his triumphs with enthusiastic sympathy as the confirmation of the prophetic aspirations for their national deliverance. In the

Old Testament he is called the Shepherd and the Anointed of Jehovah, because in 538 he gave the Jews who were living in captivity in Babylon permission to return; yet it is expressly said of him: 'For Jacob My servant's sake, and Israel My chosen . . . I (Jehovah) have surname (or *called*) thee, though thou hast not known Me . . . I will gird thee, though thou hast not known Me' (Isa. xlv. 4, 5). The favour which he showed to the Jewish people awoke the hope that he might be won over to faith in Jehovah as the one true God; but doubtless he was less moved by religious than by political motives to allow the Jews to return to their own land. After the great king had extended the boundaries of his empire from the Arabian desert and the Persian Gulf in the south, to the Black Sea, the Caucasus, and the Caspian in the north, he died in 528—according to Herodotus and Diodorus, during an unsuccessful struggle with Tomyris, queen of the Massagete, on the Jaxartes; according to Ctesias, of a wound which he had received while conquering the Derbices on the upper Oxus. The empire of Cyrus was organised under satraps and minor governors, after the manner of the second empire of Assyria. Three years before his death, Cyrus made his son and successor Cambyses 'king of Babylon.' His own title was 'king of the world.' The chief seat of his court was Ecbatana; during the spring months it was held at his old capital, Susa, or Shushan, in Elam. Cyrus takes a high rank among Asiatic conquerors; he was a wise and considerate ruler, whose aim was to soften by his clemency the despotism which he was continually extending by the sword. But he did little to consolidate the empire which he founded, contenting himself with a declaration of allegiance, and leaving the government nearly everywhere in the hands of native rulers. He brought the greater part of the Old World (Egypt excepted) under his sway, but left the organisation of his conquests to his successors. The *Cyropædia* of Xenophon is obviously an historical romance. See Professor Sayce's *Introduction to Ezra, Nehemiah, and Esther* (2d ed. Lond. 1887); also his *Fresh Light from the Ancient Monuments* (1883).

**CYRUS THE YOUNGER**, the second of the sons of Darius Nothus (or Ochus) and Parysatis, was born in 424 B.C. He conspired against his brother Artaxerxes Mnemon, who had succeeded to the throne (404 B.C.). The plot, however, being discovered, he was at first sentenced to death, but afterwards pardoned, and even restored to his dignity as satrap of Asia Minor. Here he employed himself in making arrangements for war against his brother, although he concealed his purposes to the very last. In the spring of 401 B.C. he left Sardis at the head of 100,000 Asiatics and 13,000 Greek mercenaries, under pretence of chastising the robbers of Pisidia. Artaxerxes being warned of Cyrus's perfidy, made preparations to oppose him, and the two armies encountered each other in the plains of Cunaxa, 500 stadia from Babylon. Cyrus was defeated and slain, although the Greeks fought with the greatest courage, and even routed that portion of Artaxerxes' troops immediately opposed to them. The fortunes of the Greeks, on their retreat through the highlands of Armenia, in severe winter-weather, are recorded by Xenophon in his *Anabasis* (q.v.).

**Cyst** (*kystis*, 'a bladder'), a word sometimes used in the original sense as applied to hollow organs with thin walls, as the urinary bladder and gall-bladder; but commonly reserved for the designation of pathological structures or new formations within the body having the bladder form. Cysts may arise in two different ways: (1) either

by the accumulation or products within cavities normally present, or (2) by the independent formation of a cavity. Of the first, wens, collections of secretion in a sebaceous gland of the skin, are the commonest example; instances of the second are cystic tumours of the Ovary (q.v.) and the sacs developed in connection with certain parasites ('bladder-worms'; see HYDATIDS, ENTOZOA). The structure of their walls is still more variable than their mode of origin; sometimes they are thin and transparent, sometimes dense and fibrous. They are either simple or compound, unilocular or multilocular; they are sometimes small, numerous, and separate; in other cases they grow to an enormous size, and are very complex. Some cysts are present at birth, and remain through life almost unchanged; some increase rapidly in size, and form large and dangerous tumours. For Cystic Worms, Cysticercus, see BLADDER-WORM, CESTOID WORMS, TAPEWORM.

**Cystin**, or CYSTIC OXIDE, forms a rare variety of urinary Calculus (q.v.). Its chemical composition is  $C_3H_7NSO_2$ , and it forms a whitish or dirty yellow deposit of six-sided crystalline tablets. It is soluble in ammonia, and is thereby distinguished from the similar crystals of uric acid.

**Cystitis**, inflammation of the Bladder (q.v.).

**Cystoidea** (Gr. *kystis*, 'a bladder'), a group of fossil echinoderms, so called from their spherical or bladder-like form. The spherical body was inclosed by calcareous plates, and resembled that of the crinoids in general form. It was borne on a short stalk, or was sessile. See CRINOIDEA.

**Cythera**. See CERIGO.

**Cytisus**, a large genus of Leguminosæ, sub-order Papilionaceæ, small trees or shrubs, with ternate leaves, and yellow, white, or purple flowers, natives chiefly of the warmer temperate parts of the Old World, but frequently introduced on account of the beauty of their flowers; see BROOM. In its widest sense the genus may include the Laburnum (q.v.).

**Cytology**. See CELL.

**Cyzicus**, the ancient name of a peninsula of Asia Minor, projecting into the Sea of Marmora, which lies immediately to the SE. of the island of Marmora, and is about 9 miles in length. It was at one time an island. In early times Cyzicus was a Milesian colony, and the city of Cyzicus, which was not finally ruined till its conquest by the Arabs in 675, is described by Strabo as one of the first cities in Asia, alike for extent and splendour. See Hasluck, *Cyzicus* (1911).

**Czar**, better *Tsar* or *Tzar*, the title of the emperors of Russia and kings of Bulgaria. The word occurs in Old Slavonic, equivalent to king or *kaiser*, and is connected with the Latin *Cæsar*, continued in the Roman empire as a title of honour long after the imperial house itself had become extinct. In the Slavonic Bible the word *basileus* is rendered by *czar*; *Cæsar* (*kaisar*) by *Cesar*. In the Russian chronicles also the Byzantine emperors are styled czars, as are also the khans of the Mongols who ruled over Russia. The title of the Russian princes was *kniaz* ('prince') and *veliki kniaz* ('great prince'): and the princes of Moscow took the title of czar as rulers of the Mongolians. As individual subkhans made themselves independent of the kingdom of the Golden Horde, they also assumed the title of czar; thus, there were czars of Siberia, of Kasan, and of Astrakhan. The conquest of the Golden Horde by the khan of the Crimea in 1480 made the grand-princes of Moscow completely independent; and upon them devolved the absolute power which the czars had exercised over all Russia. Ivan IV. the Terrible first caused him-

self to be crowned czar in 1547; from that time the title of czar became the chief title of the Muscovite rulers, and became practically the equivalent of emperor. The wife of the czar was named *tsaritz*a (czarina); the sons, *tzarevitch*; the daughters, *tzarevna*; but after the death of Alexei—Peter I.'s son—these titles were abolished, and the imperial princes were called grand-dukes, and the imperial princesses grand-duchesses. In 1799 the Emperor Paul I. introduced the title of *cesarevitch* (not *czarevitch*) for his second son, the Grand-duke Constantine. The heir-apparent and his wife continued to be called *cesarevitch* and *cesarevna*. Among the Russian people themselves, the emperor was more frequently called *Gossudar* (Hospodar, 'Lord') than czar. The term White Czar, *belyj zar*, comes down from Mongol times, and is merely equivalent to an independent, non-tribute-paying czar. The czardom ended in the revolution of 1917. See RUSSIA.

**Czardasch**, or CSÁRDÁS, a Hungarian national dance, in two sections—a slow movement called a *lassu* or *lassan*, and a quickstep, the *friss* or *friska*. Both are always in  $\frac{3}{4}$  or  $\frac{2}{4}$  time, and in the same key. Examples on an extended scale occur in Liszt's 'Rhapsodies Hongroises.'

**Czartoryski**, ADAM GEORGE, son of Prince Adam Czartoryski (1734–1823), was born at Warsaw, 14th January 1770. Educated at Edinburgh and London, he returned to Poland, and took part against Russia in the war of 1794. Sent to St Petersburg as a hostage, he gained the friendship of the Grand-duke Alexander and the confidence of the Emperor Paul, who made him ambassador to Sardinia. When Alexander ascended the throne, he appointed Czartoryski assistant to the Minister of Foreign Affairs; and he took an active part in official life until after the peace of Tilsit. As curator of the university of Wilna (1803) he exerted all his influence to keep alive a spirit of nationality; and when some of the students were sent to Siberia on a charge of sedition, Czartoryski resigned his office. His successor reported to the emperor that the amalgamation of Russia and Lithuania had been delayed a century by Czartoryski. Russian favours could not deaden or even dull Czartoryski's pure patriotism. Into the revolution of 1830 he threw himself with all his heart. He was elected president of a provisional government, and in this capacity summoned a national diet, which in January 1831 declared the Polish throne vacant, and elected Czartoryski head of the national government. He immediately devoted half of his large estates to the public service, and adopted energetic measures to meet the power of Russia. In August he resigned his post, but continued to fight as a common soldier. After the suppression of the rising (see POLAND), Czartoryski—specially excluded from the general amnesty, and his estates in Poland confiscated—escaped to Paris, where he afterwards resided, the liberal friend of his poor expatriated countrymen, and the centre of their hope of a revived nationality. In 1848 he liberated all his serfs in Galicia, and during the Crimean war he ineffectually endeavoured to induce the allies to identify the cause of Poland with that of Turkey. He refused the amnesty offered to him by Alexander II., and died 15th July 1861. See his *Memoirs*, translated by Gielgud (1888), and Morfill's *Poland* (1893).

**Czaslau** (Bohemian *Cáslav*), a town of Bohemia, 40 miles ESE. of Prague by rail, with manufactures of beet-sugar and alcohol. Its church, in which the Hussite leader Ziska was buried, is surmounted by the highest steeple in Bohemia (290 feet). The place was the scene of

an important victory gained over the Austrians by Frederick the Great, 17th May 1742. Population, 10,500.

**Czechoslovakia**, a republic of central Europe, established in 1918 out of the ruins of the Austro-Hungarian monarchy. It consists of the Czech territories (Bohemia, Moravia, Silesia) of former Austria, together with the Slovak territory (Slovakia), and the Little Russian territory (Carpathian Ruthenia) of former Hungary. In shape and size not unlike Great Britain, it lies from west to east, and, situated at the heart of Europe, borders on Germany, Austria, Hungary, Rumania, and Poland. It is some 600 miles in length, and about 55,000 square miles in area (Bohemia, 20,333 sq. m., Moravia, 8580 sq. m., Silesia, 2026 sq. m., Slovakia, 19,148 sq. m., Ruthenia, 4958 sq. m.). Geographically the country may be divided into two main sections, separated roughly by the valley of the March (Morava): the first comprises the whole of Bohemia, the western and north-western part of Moravia, and the Silesian district of Troppau (Opava); the second includes Slovakia, the adjoining portion of Moravia, the Silesian district of Teschen (Těšín), together with Carpathian Ruthenia. The first part, sloping downwards from south to north, forms the basin of the upper Elbe, and is a network of waterways drained by the Moldau (Vltava) and the Elbe (Labe), both of which are navigable far inland. On the south and south-west this region is enclosed by the Sumava and the Bohemian Forest, on the north-west by the Ore Mountains (Krušné Hory, Erzgebirge), in the north and north-east by the Giant Mountains (Krkonoše, Riesengebirge) and the Sudetic Mountains; in the east the Czecho-Moravian plateau allows of easy communication with the second geographical section of the country. This section consists of the western and northern range of the Carpathians, and slopes not northwards but southwards from the heights of the High Tatras to the Danube and the plain of Hungary; the March of Moravia and Slovakia, and the Vah, Nitra, Hron, and Ipola of Slovakia flow southwards to the Danube; while the rivers of Carpathian Ruthenia, mostly of small importance, run mainly south-westwards to the Theiss (Tisza). The principal lakes of Czechoslovakia are the Lagenbrücher Teich of Bohemia and Lake Csorba of Slovakia. The climate of the republic is a mean between the maritime and the continental, its continental character increasing from west to east. Rainfall is generally even, and temperature varies with altitude, the warmest part being the large plain crossed by the tributaries of the Danube in their lower reaches. The winter in Bohemia, Moravia, and Silesia lasts only two and a half months, but in Slovakia and Carpathian Ruthenia winter is severe and summer hot, while spring and autumn are short.

**Agriculture.**—In Slovakia is to be found some of the richest soil in Europe, and throughout Czechoslovakia agriculture is highly developed, the country being almost self-supporting. Wheat, rye, barley, oats, maize, sugar-beet, and potatoes are the principal crops, while the Saaz (Žatec) district of Bohemia is famous for its hops. Much live-stock (cattle, horses, pigs, sheep, and goats) is raised. In many districts fruit-growing, especially the culture of the vine, is largely carried on. The forest wealth of the country is great. The question of land reform was tackled early by the republic, and by an act of 1919 the state was empowered to expropriate and break up large estates, many of which for almost three centuries had lain in the hands of German nobles.

**Manufactures.**—Despite its agricultural importance Czechoslovakia is, however, essentially an

industrial country, and at that one of the richest in Europe, about 80 per cent. of the mines and industrial enterprises of the former Austro-Hungarian monarchy now lying within the republic. Sugar, alcohol, beer malt, textiles (cotton, wool, flax, jute, &c.), porcelain, pottery, glass (window, mirror, bottle, lamp chimney, electrical globe, cut and crystal, chemical, watch, fancy), chemicals (manures, dyes, soap, candles, glue, &c.), timber, leather (gloves, boots), furniture, fancy goods, paper, machinery (agricultural, sugar, brewery), steel, iron, and other manufactures in metals are the principal industries. The sugar industry is very great, Czechoslovakia being among the first beet-sugar producing countries of the world, and the only European sugar exporter. The industry centres chiefly in Bohemia and Moravia, as does also the famous (Pilsner) beer-brewing industry. The important distilling-industry is pretty generally distributed. The textile industries are highly developed; cotton, the most important, is concentrated chiefly in north-eastern Bohemia and in Slovakia; the woollen industry centres in Bohemia and Moravia, and the flax and jute industries in these provinces and also in Silesia. Silk, hemp, lace, embroidery, and hosiery are also manufactured. The great glass and porcelain industries are localised mainly in Bohemia, the first in the sandy districts near the coalfields of the north-west, the second round Carlsbad and in the smaller towns and villages of the west. The iron and steel industry, with its principal centres in Bohemia, Moravia, Silesia, and Slovakia, is greatly hampered by insufficient native supplies of iron ore. Czechoslovakia abounds in water power, and since the establishment of the republic the state has undertaken the systematic utilisation of that power for the industrial electrification of the country.

**Minerals.**—The minerals of Czechoslovakia are as varied as they are extensive. Coal is the chief, and, though not exported, forms a most important source of supply for native industry. The great field is in Silesia (Ostrava-Karvin), but large supplies are got also from Bohemia (Kladno, north of Prague) and to a lesser extent from Moravia. Lignite in large quantities is mined mainly in Bohemia, but also in Slovakia and Carpathian Ruthenia. Bohemia and Slovakia are the principal sources of iron ore, while in the first of these provinces and in Moravia graphite is an important industry. Apart from these minerals, gold, silver, wolfram, uranium, radium, copper, tin, antimony, lead, zinc, sulphur, manganese, aluminium, kaolin, and quartz are all found in different parts of the country, but mostly in Bohemia. In some parts mineral oils are worked, while in Carpathian Ruthenia there are great mines of salt. Garnets are obtained in Bohemia and opals in Slovakia. Round the many mineral springs of the country numerous health-resorts have arisen, the most famous Carlsbad (Karlov Vary), Marienbad (Mariánské Lázně), Franzensbad (Františkovy Lázně), Teplitz-Schönau (Teplíce-Sanov), Luhačovice, Priesnitz, Gräfenberg, Postyén (Píšťany), Vyhne, and Sliač.

**Commerce.**—As an essentially industrial state, Czechoslovakia imports chiefly raw materials and foodstuffs, and exports finished manufactured goods. Corn, flour, wool, cotton, ores, oils, &c., are the principal imports; and sugar, glass, timber and wooden goods, beer, iron, machinery, paper, leather and leather goods, textiles, &c., the leading exports. Though hampered commercially by lack of seaboard, Czechoslovakia's position at the heart of Europe, and in close proximity to the agricultural states of Poland, Hungary, and Rumania, is economically advantageous. With most of the countries

of Europe commercial treaties were concluded soon after the emergence of the republic.

*Communications.*—An inland state, Czechoslovakia is peculiarly dependent on the efficiency of her internal means of communication. The road-system generally is well developed, but that can hardly be said of the waterways, no real systematic attempt having been made to turn to advantage the potentialities of the country for canalisation. While the navigable rivers are few, those there are of great importance. The Elbe, with its navigable tributary the Moldau, and the Danube are the chief, while the Oder is navigable from Czechoslovakia to the Baltic. By the Elbe, Prague (Praha), the capital, is linked with Hamburg, while by the Oder the industrial regions of Silesia are joined to Stettin; in both ports Czechoslovakia by the Treaty of Versailles (1919) enjoys special commercial privileges. In Carpathian Ruthenia the Theiss provides in part a navigable highway. Operations for linking up the Elbe and the Danube by canal have been begun, while an Oder-Danube canal scheme is also to be undertaken. The railways of Czechoslovakia, owned partly by the state and partly by private enterprise, form a dense network, more especially in the western provinces of the republic. As an integral part, however, of the former system of Austria-Hungary they run mainly from north to south, whereas the circumstances of the new state demand rather a system with connections from west to east. For the improvement of railway communications along those lines national funds have been allocated. Internationally Czechoslovakia may be regarded as the railway centre of Europe; thus Prague, standing on the great trans-continental routes, is joined by rail to the capitals of almost every European state.

*Population.*—The population of Czechoslovakia in 1921 was about 13,610,405, including 8,761,834 Czechs and Slovaks, 3,122,892 Germans, 746,809 Magyars, 459,349 Ruthenes, 180,337 Jews, 75,705 Poles. The Czechs and Slovaks form two branches of the same Slav stem, and constitute the western vanguard of their race. The Czechs occupy central and southern Bohemia and the central districts of Moravia and Silesia. The Slovaks inhabit northern Slovakia and central Silesia. The German population centres mainly on north-western Bohemia, in western Silesia, and in a small district on the boundary of Bohemia and Moravia. The Magyars inhabit southern Slovakia and south-western Ruthenia. The Ruthenes of Little Russian (Slav) stock are to be found on the eastern border of Slovakia and in Carpathian Ruthenia, on a strip of about forty miles wide running along the Carpathians. The Jews are widely distributed, but are most numerous in the east, and are for the most part town-dwellers. The Polish population is concentrated mainly in eastern Silesia.

*Education.*—Under Austrian rule education, both general and technical, was always widespread and of a high standard in Bohemia, Moravia, and Silesia, the race rivalries of Czech and German having proved beneficial in this regard. In Slovakia, however, teaching in the national language was forbidden under the Magyars, and the percentage of illiteracy was high, while in Carpathian Ruthenia education was even more backward. From the year of its establishment, however, the furtherance of education was one of the first cares of the Czechoslovak state, and instruction became compulsory in primary, secondary, commercial, and agricultural schools. In Slovakia, in the first year of the republic, three thousand Slovak schools were opened, while educational improvement was also undertaken in Carpathian Ruthenia. Of higher learning there are numerous institutions in Czechoslovakia. Apart from a school of mines, an academy of arts,

and two high schools of agriculture and veterinary science, there are four high schools of technical studies (two Czech, two German), two academies of law, and three faculties of divinity, all of university standing. Of universities there are four, two in Prague, one Czech, one German; the former founded in 1348, the latter in 1882. A new Czech university was established at Brünn (Brno) in 1918, and a Slovak university was instituted at Pressburg (Bratislava) in 1919.

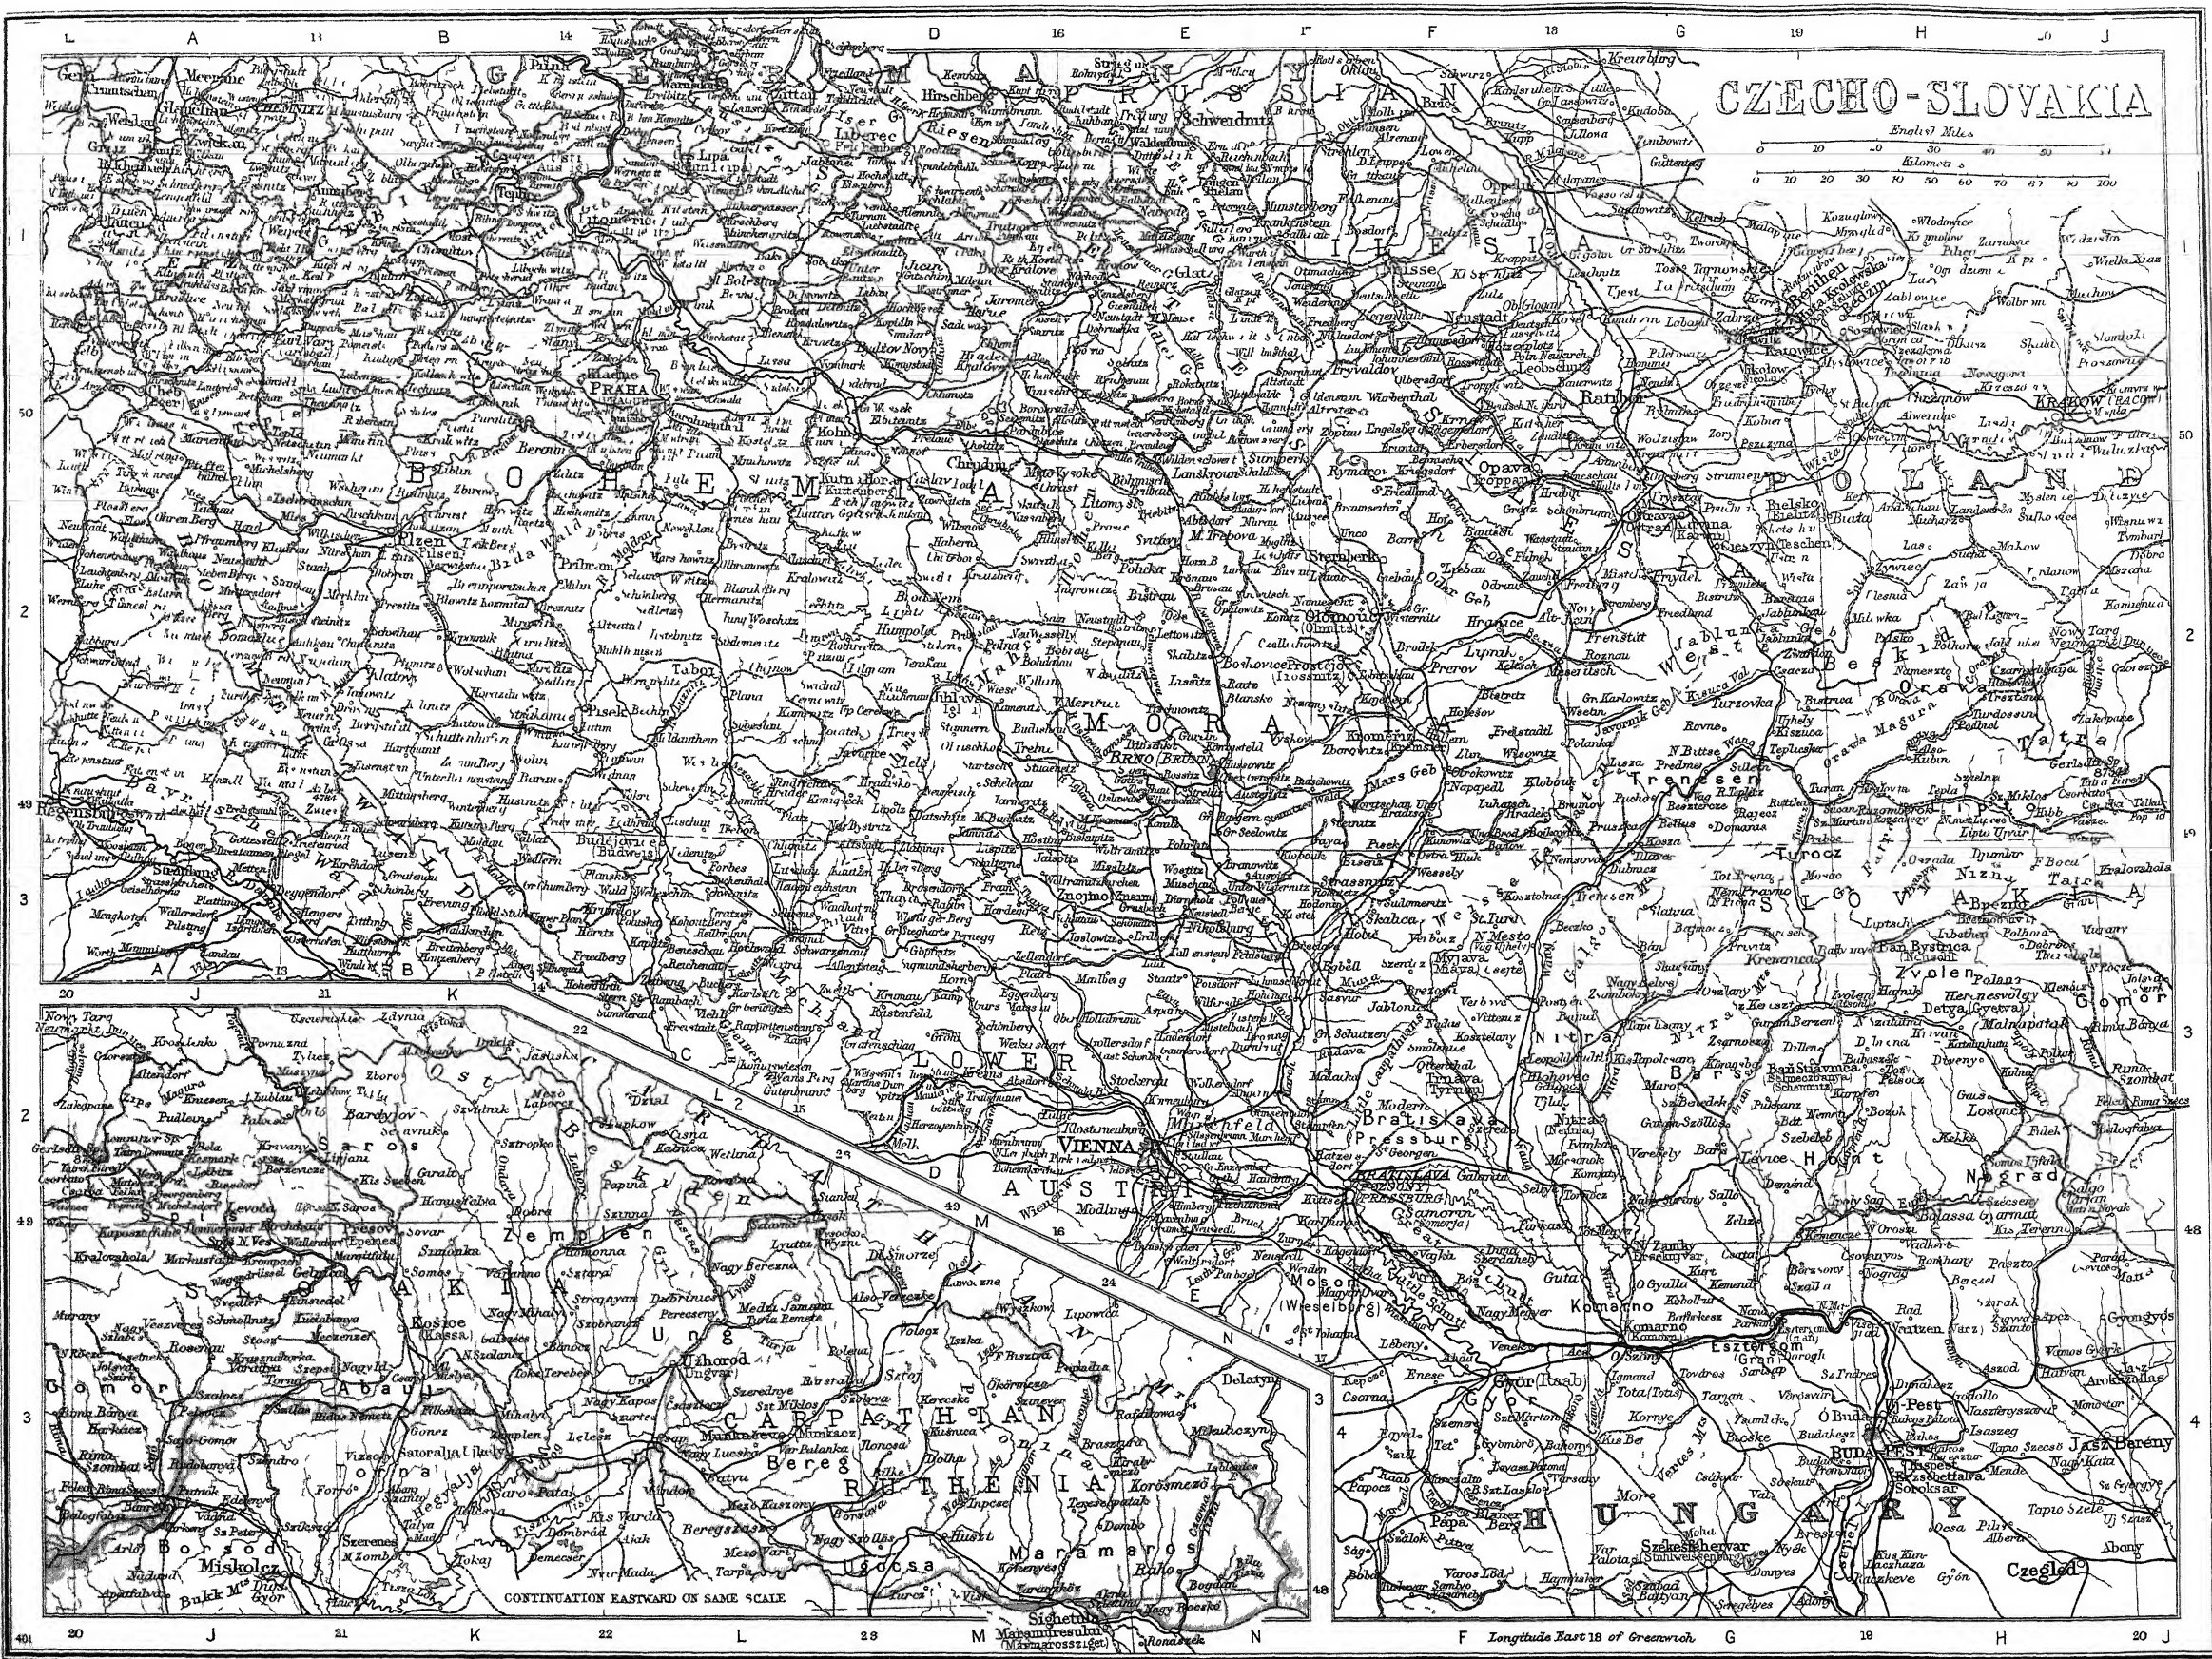

*Religion.*—By the Czechoslovak constitution liberty of conscience and of religious creed is guaranteed, while in the eyes of the law all religious confessions are equal. The state, by means of financial grants, supports the various ecclesiastical communities in their moral and educational activities, and allows the churches to organise their work freely, according to their own principles and needs. Owing to the Counter-Reformation of the Hapsburgs in the 17th century, the nation which led the Reformation in central Europe is to-day overwhelmingly Roman Catholic, the percentage of Protestants (Lutherans and Calvinists) being altogether insignificant. The adherence of the Czechs to the Roman Catholic Church is, however, often merely nominal, and in the 20th century a strong tendency to secession became manifest, more especially among the intellectual and working-classes. The republic gave strength to the movement, and in the first three years of its existence over a million persons forsook the Roman faith, the greater part joining a newly-formed National Church. This church arose out of the Holy See's rejection of a request for reform put forward by a considerable section of the Czechoslovak priesthood, the reforms demanded including the abolition of celibacy, the introduction of the vernacular into the services, and a more democratic administration of church affairs. The Ruthenes belong to the Uniat Church, to which also belong some of the Slovaks in the eastern districts of Slovakia.

*History.*—The emergence of the independent state of Czechoslovakia represents the last stage in the revolt of the Slav people of central Europe against the Germanising and Magyarising influences which surrounded them. For the first stages of that revolt one must turn to the earlier history of the various territories which came later to constitute the republic.

*Bohemia.*—The Celtic Boii, from whom the country derives its name, were the first known inhabitants of Bohemia. They were expelled about the beginning of the Christian era by the Teutonic Marcomanni, who yielded in turn to the great Slav invasion, and as early as the 5th century Bohemia was peopled by Czechs. Under Samo, a mysterious alien, their kingdom attained in the 7th century to large dimensions. During the 9th century Bohemia formed part of the great Moravian realm of Svatopluk, and was converted to Christianity by the Greek monks Cyril and Methodius. On the fall of Svatopluk's empire in the 10th century, Bohemia was ruled by a line of dukes of the Czech dynasty of Přemysl. These dukes owned the overlordship of Germany, and from 1086 their kingship was acknowledged, Bohemia being regarded as a state in the German empire. In 1306 the last of the dynasty was assassinated. Under its sway the growth of German influence, in many ways beneficial, was very marked, and the country became bilingual. Reaction came, however, with the succeeding house of Luxemburg (1310-1437), and under Charles I. of Bohemia, IV. of Germany, the Czech movement first took definite shape in both its aspects, religious and political. The great movement for church reform, inaugurated in the following reign by John Huss (q.v.) and Jerome of Prague (q.v.), became with the martyrdom of Huss

(1415), and the employment of Germany as the crusading force of the Roman Church, as much national as religious in character, and the Hussite wars (1420-36) were racial wars in large degree. Victory lay with the Hussites, but the country was grievously weakened. Many difficulties stood thereafter in the way of the erection of a permanent Slav monarchy, Bohemia became an elective kingdom, and in 1458 the Protestant noble, George of Podiebrad, ascended the throne. With his successor, the Polish prince Ladislaus (1471-1516), came association with the kingdom of Hungary, for in 1490 Ladislaus was elected to the Hungarian throne. Under him the royal residence was removed to Ofen (Hungary), where also his son and successor, Louis (1516-26), resided. After Louis's death in battle against the Turks at Mohacz, Bohemia and Hungary passed into the hands of the Hapsburgs under Ferdinand I. of Austria, who had married Louis's sister, and from that time till the rise of the Czechoslovak republic the history of Bohemia merges in that of Austria (q.v.). The Reformation was tolerated under Maximilian, and religious liberty was formally granted by Rudolf II. (1609); but under Matthias, and especially Ferdinand II., this freedom was later withdrawn. This reactionary religious policy of the Hapsburgs, joined to the centralising absolutism of their house, produced the revolution of 1618, and saw the election of Frederick V. of the Palatinate (q.v.) to the Bohemian throne (see THIRTY YEARS' WAR). With the disastrous battle of the White Mountain (1620), however, the Hapsburgs were restored. There followed the merciless extirpation of Protestantism, the triumph of Jesuitism, the ruin of the country, the suppression of Bohemia as a nation. But in the latter part of the 18th century the reforms of Josef II., and the influence of patriotic writers, stirred up a revival of national feeling, more especially in the departments of language and literature. And so in the earlier part of the century following, till in 1840 the movement became definitely political in character. A continuous demand for the restoration of political independence ensued. In 1848 a Pan-Slav congress was held at Prague, and in the same year a revolutionary rising was swiftly suppressed in that city. A return to absolutism followed, but in 1861 a more liberal constitution was granted; Bohemia enjoyed a diet (*Landtag*) of its own, while it also sent members to the imperial parliament (*Reichsrat*) at Vienna. Under the new constitution a Bohemian diet made the Czech language a compulsory subject even in German secondary schools. In 1867, however, the Czechs refused to send their complement of members to the Reichsrat, on the ground that that body encroached on the rights of the Bohemian diet. In other ways the Czechs showed their growing sympathy with Pan-Slavism. About this time the industrial revolution, which was beginning to transform Bohemia, gave a new stimulus to the national cause, in so far as Czech workmen now massed together in factories gained a new sense of racial solidarity. From 1871 a policy of conciliation was followed by the Austrian government, and in 1879 the Bohemian delegates resumed attendance at the Reichsrat, and as a section of the Right secured important concessions to the cause of nationalism. Solution by compromise was attempted in 1890, and at various later dates right up to the outbreak of the Great War, but all without success.

**Moravia.**—Moravia was anciently occupied by the Quadi, who were succeeded after the 5th century by the Rugii, the Heruli, and the Longobardi, and finally in the 6th century by the Slavs. Charlemagne brought the people under nominal subjection, and about 864 Christianity was first

introduced by Cyril and Methodius. In the late 9th century Svatopluk, king of Moravia, established a powerful empire, which fell, however, in the century following, before the onslaughts of the Magyars. In 1029 Moravia became incorporated with Bohemia, and from that time till 1849, when it was formally separated and declared a distinct province and crown-land of Austria, the history of the two countries is for all intents and purposes one. As part of Bohemia, Moravia had shared in the national aspirations of the Czechs, and even after her formal separation in 1849 her growing and active sympathy with the nationalist and anti-Teutonic movement of the Bohemians was the most outstanding feature of her history.

**Austrian Silesia.**—Austrian Silesia came into being as a result of the Treaty of Berlin (1742), confirmed by the treaties of Dresden (1745) and Hubertsburg (1763), whereby there passed from Austria to Germany 'all Silesia except Teschen and the district beyond the river Oppa and the high mountains.' In the 13th century the Slav inhabitants of Silesia (q.v.) were largely Germanised, and from 1331 to 1742, during which time the country remained almost continuously a province of Bohemia, similar forces were at work. After 1742 the portion of Silesia remaining to Austria was counted, not as a Bohemian, but as an Austrian province. In 1848, however, and in 1868, the Bohemians included Austrian Silesia in their demand for the reconstitution of the ancient kingdom of Bohemia.

**Slovakia.**—The Slovaks reached central Europe probably about the same time as the Czechs, in the 5th or 6th century A.D., and at once came into contact with German tribes, to whom they were subject for a time. Later they formed part of the great Moravian empire. After being conquered by the Magyars in the 10th century, the Slovaks, except for a brief period of connection with Poland under Boleslav the Brave (973), remained till 1918 the subjects of Hungary, their history in its main lines being contained in the history of that country (see HUNGARY). Despite the Magyar influences to which from the 10th century they had been subject, the growth of a conscious feeling of nationalism was slow amongst the Slovaks. Not till the second half of the 18th century, indeed, did a national movement arise—the response to the Magyar attempt to express their own nationalism at the expense of a Slovak minority. The wave of national feeling which, after the Treaty of Vienna (1815), began to sweep over Europe, later gave strength to the movement, and when in 1848-49 the Magyars attempted to throw off the Austrian yoke, the Slovaks took the opportunity of rising against their oppressors. Their failure resulted in their continued subjection, while the feeling of hostility between the two races was increased. The compromise of 1867 sacrificed the interests of the Slovaks, leaving them more completely at the mercy of the Hungarian government. Though the Law of Nationalities of 1868 was conciliatory in spirit, in practice the forcible suppression of the Slovaks continued—political and administrative office was closed to them, their children were reared as Magyars, their language was banished, their schools were closed. Right up to the Great War the Magyars, in defence of their own political predominance, checked Slovak nationalism at almost every point.

**Carpathian Ruthenia.**—The origin of the Ruthenes is obscure, but by the 10th century Ruthenian tribes are to be found both to the north and to the south of the Carpathians, inhabiting a country which came to be known as Red Russia. There they were ruled by a number of independent princes, whose various states soon became the battle-ground of contending Pole and Hungarian, falling in whole

on in part, now to the one, now to the other. From 1382, however, till 1918 the region on the south-western side of the Carpathians (Carpathian Ruthenia) remained continuously in the possession of the crown of Hungary, its history being the history of that country. Under Hapsburg rule, Ruthenian nationalism in Carpathian Ruthenia, as in the other Ruthene territories of the empire, was for long encouraged, partly as a means of checking the Galician Poles, partly with a view to creating a national nucleus, to which in course of time might be attracted the Little Russian subjects of the Russian empire. In the later 19th century, however, and in the first years of the 20th, this policy was in large measure reversed. Thus the imposition of the Magyar liturgy was attempted, while a general attitude of hostility to the Uniat Church was adopted. It was in these circumstances that in the decades before the Great War a strong nationalist and anti-Magyar movement arose amongst the Ruthenes. See GALICIA, POLAND, RUTHENIANS, UKRAINE.

While the tide of national feeling among the Slav peoples of central Europe continued to rise as the 20th century advanced, the outbreak of the Great War found the national aspirations of Czech, Slovak, and Ruthene still unsatisfied. It fell, however, to the war to provide the circumstances in which the realisation of national ambitions became possible. From the very outset Czechs and Slovaks were unconcealed opponents of the Austrian cause. In the field they surrendered in battalions to the Russians and the Italians, and joined with them and with the French to fight the Central Powers; at home they suffered persecution for pro-Ally sympathies; abroad, in the countries of the Allies, especially under Professor Mašaryk and Dr Beneš, they instituted a political campaign against the empire of which they formed so unwilling a part. Over three years elapsed, however, before events at home began to move directly towards the institution of an independent state. In December 1917 the Czech deputies of the Reichsrat declared that, on the conclusion of the war, the only possible terms of peace must include the recognition of the right of the Czechoslovak nation to self-determination. This announcement was followed on 6th January 1918 by a Declaration of Independence, issued at Prague by the Czech deputies of the Reichsrat, and by the deputies from the diets of Bohemia, Moravia, and Silesia. In the Declaration, amongst other things, union with Slovakia was claimed. On 13th July following, in the interests of an independent state, a National Council was instituted at Prague. Thereafter, at different times, the Czechoslovak claim to independence was virtually acknowledged by France, Italy, Great Britain, the United States, and Japan. On 14th October the National Council was constituted as a provisional government, and on the 27th, the rights of the Czechoslovaks were recognised by the Austro-Hungarian government, following the rejection of its offer of a measure of national autonomy within an Austrian federation. So it came to pass that on 28th October 1918 the National Council, without resistance, took over the government of Bohemia, Moravia, and Silesia, the ancient kingdom of Bohemia being in this way once more reconstituted. Two days later the independence of Slovakia was also proclaimed, and political union with that country accomplished. On 14th November following the first representative body of the Czechoslovak people—the National Assembly—met at Prague, where the Czechoslovak state was formally declared a republic, and Professor T. G. Mašaryk was elected as its first president. On 8th May 1919 Carpathian Ruthenia, in a National Central Council, unanimously approved of incorporation

with Czechoslovakia on special terms of autonomy, political action in this direction having previously been undertaken by emigrant Ruthenes in the United States. The request was later granted, and so, by the express will of their several peoples, the Slav territories of central Europe united to form one state, with a single government. The frontiers of Czechoslovakia were fixed by the peace treaties of Versailles (1919), St Germain (1919), and Trianon (1920), and in the case of the ancient principality of Teschen, part of which passed to the republic, part to Poland, by a decision of the Ambassadors' Conference, 28th July 1920, and not by plebiscite as originally intended.

*Constitution.*—The constitution of the Czechoslovak republic was passed by the National Assembly on 29th February 1920, and in its main provisions was largely influenced by the constitutions of France and of the United States. Thus the Czechoslovak state is declared to be a democratic republic, having an elected president at its head; the state, with the partial exception of Carpathian Ruthenia, is to be unified and not federative; the legislative body is to consist of two chambers—a chamber of deputies of 300 members and a senate of 150 members—both elected by a universal, equal, direct, and secret suffrage, according to the principles of proportional representation; complete and absolute security of life and of personal freedom are to be guaranteed to all; in respect of civic rights, no privileges of sex, birth, or vocation are to be recognised; liberty of speech, press, instruction, and religious profession are assured; all religious confessions are to be equal in the eyes of the law; all citizens are to be equal whatever their race, language, or religion, while special provisions are to be made for the protection of national, religious, and racial minorities.

*Language.*—Linguistically as racially the Czechs and Slovaks are one people, and by the constitution of Czechoslovakia, the Czechoslovak language in both its forms, the Czech and the Slovak, is declared to be the official language of the republic. Czech and Slovak as tongues are mutually intelligible, and are so similar that one might almost be said to be a dialect of the other. In reality they represent two branches of the same Slav language, but branches exposed to divergent influences. Till the 19th century Czech was the literary language not only of Bohemia, Moravia, and Silesia, but also of Slovakia. Czech is one of the most cultivated dialects of the Slavonic, and in its complicated and difficult forms reminds one of the Latin and Greek accident. Its peculiarities are the sibilated *r*, which is harsher than the *rz* of the Poles, and the distinct possession of both quantity and accent, so that Latin and Greek metres can be exactly reproduced in it, though such imitations are purely artificial, the native poetry being accentual. Its syntax resembles Latin. It has one guttural, *ch*. It has a passive participle, but no formal passive voice, and makes a very free use of reflexive verbs. In their Uniat Church the people of Ruthenia have preserved the Slav liturgy, but their language is a dialect of Little Russian.

*Literature.*—The literature of Czechoslovakia is mainly Czech, though also Slovak to some extent. There is no Ruthenian literature of importance.

*Czech.*—The Greek Church is represented by a Glagolitic (q.v.) fragment (c. 900), the Latin by a fragment of St John's Gospel with an inter-linear Czech translation of somewhat later date. Between 1240 and 1250 the Latin *Alexandreis* was freely translated into rhyme, and legends of Christ and of several saints were current towards the close of the century. A manuscript containing

an unrhymed poem, the *Judgment of Libussa*, and another containing epic and lyric poems were found by V. Hanka in 1817; the work has been ascribed to the end of the 13th century, but both manuscripts are now usually regarded as forgeries. The greater part of the Bible was translated by the end of the 13th century, and in the 14th the whole was completed, the Czechs being the first Slav nation to possess a complete translation of the Scriptures in their native language. The first half of the 14th century, important as witnessing the foundation of the university of Prague by Charles IV. in 1348, presents a rhymed chronicle called that of Dalimil, the earliest complete manuscript of which (c. 1350) was unearthed at Pembroke College, Cambridge, in 1876. In this century didactic and satirical poetry were well represented. The rhymed legend of St Catherine (discovered at Stockholm in 1850) is of considerable beauty, and that of St Prokop is amusing. The travels of Marco Polo were translated early, and those of Sir John Mandeville late in the same century. A cycle of chivalry was also current. A complete Life of Christ was written. Romances of Alexander the Great and of Troy were translated. Tkadleczeck's dialogues between 'The Complainer' and 'Misfortune' are a model of terse and elegant Czech. Thomas of Stitný (Tomáš ze Stitného, 1325-1404), one of the earliest precursors of the Reformation, wrote in order that there might be a literature of the soul as generally accessible in the Czech as in the Latin tongue. Theologian, homilist, and philosopher, his equal cannot be found in English literature before the time of Elizabeth. From Stitný, as a writer, it is impossible to separate John Huss (Jan Hus), who, though inferior in style, yet in his religious writings in the vernacular created the Czech literary language as it is written to-day. The Hussite wars were hardly favourable to any but controversial literature, though a few songs, satirical and didactic poems and ballads were produced, among them a spirited ballad on the battle of Aussig, and the marching song of the soldiers of Žižka. Žižka was the inventor of modern strategy, and his military arrangements, which still exist in writing, are in every way remarkable. In this period, too, appeared Peter Chelčický, the peasant philosopher, and probably the most original religious thinker of the time. His writings, anticipatory of Tolstoi in their doctrine of non-resistance, are an expression of the innermost spirit of the Czech people, and subsequently formed the basis on which was founded the Union of the Bohemian Brethren, a union which in the later 16th century developed a highly successful literary activity. During the Polish dynasty John Hasensteinský wrote *Travels in Palestine* (1492) and *Advice to his Son* in excellent Czech, and Nicholas Konacz a fine book on the *Plaint of Justice, the Queen and Lady of all the Virtues*. Under Ferdinand I. and Maximilian II. (1526-75) many of the Jesuits from the Jesuit academy, established at Prague in 1555, wrote in Czech with great success. Sixtus of Ottersdorf's *Memoirs of the Years 1546-47* are very valuable. But the literary glory of the period is the *Kronyka Ceska* of V. Hajek of Liboczan (1541), which in style rivals Herodotus, though its historical statements are so untrustworthy, that Palacký terms the author 'the corrupter of Bohemian history.' The time of the emperors Rudolf II. and Matthias (1576-1619), or rather of the former, marks the highest point of development of the older Czech literature. In Rudolf's time the printer, Adam of Veleslavin, was the centre of literary activity. Translations were more abundant than original works, and it was during this period that the great Kralitz (Kralická) Bible, translated by the

Bohemian Brethren, appeared at Kralitz in Moravia (6 vols. 1579-93). Matyas Gryll (1592) wrote the only good original poem, *On the Providence and Government of God*, of this era. The travels of Harant of Polzie in Palestine, Egypt, and Sinai, have been translated into German, and the adventures of Wratislav of Mitrovitz in Turkey into German, English, and Russian. Of Jirzik Zaveta's *Schola Aulica*, Balbinus said that 'if translated into Latin it need fear no criticism.' Amongst the Brethren the outstanding literary figure was Jan Amos Komenský (Comenius, 1592-1671), the great humanitarian teacher of the nations, and author of the *World in Pictures* and the *Labyrinth of the World*. From Ferdinand II. (1619) to Josef II. (1781) is a period of literary decline. The Jesuits from the school of Ferdinand I. gradually died out, and their successors, far from studying Czech, carried on a ruthless crusade against the native literature. The Jesuit Konias boasted of having burned 60,000 volumes with his own hand, and in no modern literature are so many books known to have disappeared.

But with the end of the 18th century came a period of unexampled revival. The Abbé Josef Dobrovský (1753-1829) was the pioneer; the father of Slavonic comparative philology, he devoted his life to grammatical, philological, and historical research in the interests of the Czech tongue. In 1795 Fr. V. M. Kramerus established a printing-press in Bohemia, which, till his death in 1808, was the centre of Czech literary activity. In 1818 Count Kaspar Sternberg and others succeeded in fully establishing and endowing the Bohemian Museum, which became the centre of literary and linguistic, and also scientific research and progress. In 1825 Josef Jungmann (1773-1847) published his *History of Bohemian Literature*, and in 1827 the magazine (*Czasopis*) of the Bohemian Museum appeared under the editorship of Fr. Palacký (1798-1875). In 1831 the *Matice Ceska*, the Czech Literary Society, a by-committee of the Museum, was instituted for the republication of old, and the publication of new books of value in the Czech language. By its aid Jungmann's great Czech dictionary, the work of thirty years, appeared (5 vols. 1835-39), and in 1837 the Slovak, P. J. Safarik's (1795-1861) *Slavonic Antiquities*, the first Czech work to obtain a European reputation. The first volume of Palacký's famous *History of the Czech Nation* appeared in German in 1836, in Czech in 1848; the work to 1826 was completed in German in 1867, and in Czech in 1876, and was later continued by Gindeley (1829-92). In the revival of poetry, A. J. Puchmajer (1795-1814) was an important influence, as was also V. Hanka (1791-1861) with his successful imitations of the popular songs and ballads of the peasantry (1815-16), and his publication of the *Starobyta Skladanie*, 'Ancient Collections' (1817-24)—a reproduction of the poetic stores obtained by the researches of Dobrovský. By the publication of Macpherson's *Ossian* (1761) and Percy's *Reliques* (1765) interest in folk-songs had been aroused, but the greatest impulse to Czech poetry was given by the appearance of Hanka's 13th-century manuscripts, the authenticity of these manuscripts quite apart. In 1819 Polák in his *Sublimity of Nature* produced the first great poem of the revival. Next came the Slovak, Jan Kollár (1793-1852), the poet of Pan-Slav idealism, and F. L. Čelakovský (1799-1852) and K. J. Erben (1811-70), writers of folk-songs and national ballads. K. H. Mácha (1810-36) was, however, the greatest poet of the revival; his *Máj* is a lyrical epic tinged with romantic melancholy. In Karel Havlíček (1821-56), the first great Czech publicist, Mácha's lyrical spirit had its satirical counterpart.

By the middle of the 19th century the Czech literary revival had passed far beyond its rudimentary stages, and continued to gather in strength. Jan Neruda (1834-91), in verse a Czech Heine, and in prose a Czech Dickens, is the greatest figure of the time. Both in prose and in verse the literature of these years is rich in purely popular elements. This is to be seen in the simple and delicate verses of V. Hálek (1835-74), in the strongly racial poems of A. Heyduk (b. 1835), and in the patriotic songs of J. V. Sládek (1845-1912), E. Krasnohorská (b. 1847), S. Čech (1846-1908), and F. S. Procházka (b. 1861). The progress of the novel was an outstanding feature of the time. Thus in the early fifties appeared *The Grandmother* (*Babíčka*) of B. Němcová—a rustic story and standard work of Czech literature. K. V. Rais (b. 1859), A. Stašek (b. 1843), K. Klostermann (b. 1848), the brothers Alois (b. 1861) and Vilém (1863-1912) Mrštík, and K. Světlá (1830-99), all followed in the tradition of Němcová. The social novel, generally humanitarian in purpose, also found many exponents, as G. P. Moravský (1833-75), M. Šimáček (b. 1860), J. K. Šlejhar (1864-1914), F. Herites (b. 1851), and I. Heilmann (b. 1854); while the historical novel was represented by V. B. Třebízský (1849-84), Z. Winter (b. 1846), A. Jirásek (b. 1851). J. Arbes (1840-1916) and F. X. Svoboda (b. 1860) are other novelists of note. In the poetry of the later 19th century J. Vrchlický (Emil Frida, 1853-1912), perhaps the greatest name in Czech literature, was the leading influence; a prolific writer, his many lyric, epic, and dramatic poems enriched the Czech language, and introduced almost every variety of metrical form, while his numerous translations were of great intrinsic and historical value. Vrchlický gathered round him a large group of poets, who followed him in his leanings towards perfection of form, and also in his activities as a translator; of the number are A. Klášterský (b. 1866), who completed the translation of Shakespeare begun by Sládek, J. Borecký (b. 1869), J. Kvapil (b. 1868), F. Kvapil (b. 1853), and A. Černý (b. 1864). The rallying point of the group was the *Lumír*, a literary periodical founded in the seventies, to which J. Žeyher (1841-1901), though hardly a follower of Vrchlický, was a most important contributor. Since the appearance of Vrchlický the progress of Czech poetry is associated in particular with the realist J. S. Machar (b. 1864), the impressionist A. Sova (b. 1864), and the symbolist Otakar Březina (V. Jebavý, b. 1868), three poets whose joint achievements it would be difficult to equal among modern European singers.

In the last years of the 19th century the general European revolt against prevailing artistic and moral standards made a deep impression on Czech literature. The effects of this new movement were concentrated especially in the columns of the *Modern Review*, founded in 1894. Among representatives of these modern tendencies are J. Karásek ze Lvovic (b. 1871), K. Hlaváček (1874-98), V. Dyk (b. 1877), S. K. Neumann (b. 1875), F. Srámek (b. 1877), E. Lešetický z Lešehradu (b. 1877), K. Toman (b. 1877), O. Theer (1880-1918), Jan z Wojkowicz (b. 1880), and O. Fischer (b. 1883).

The beginnings of Czech drama are to be found in the early part of the 19th century, and are associated with such names as V. Klicpera (1792-59) and J. K. Tyl (1808-56). After an interval of romanticism due to Shakespearean influences and exemplified in the plays of J. J. Kolár (1812-90), the French tradition of Scribe was followed by E. Bozděch (1841-89) and L. Stroupežnický (1850-92), the last-named introducing a more racial element in the form of village drama. By the opening of the National Theatre at Prague, 19th November 1883, a new stimulus was given

to the play. Thereafter the influence of Ibsen, together with the realism of the Russian and German stage, produced the modern social dramas of F. X. Svoboda, M. A. Šimáček, J. Hilbert (b. 1871), J. Kvapil, and K. Čapek, two of whose satirical plays, *From the Life of Insects* and *R. U. R. (Rossum's Universal Robots)* have been done in translation in London. The more recent developments of the Czech theatre have led, on the one hand, to the romantic treatment of national subjects, as in the brothers Místík, and on the other to the cultivation of historical drama, as by J. Karásek ze Lvovic, V. Dyk, J. Maria (b. 1870), A. Dvořák (b. 1880), and J. Mahen (b. 1882).

*Slovak*.—During the 15th century the spread of Hussite doctrine, from Bohemia through Moravia to Slovakia, brought with it the Czech language. Slovak at this period was still an unwritten tongue, and Czech, used at first for the new religious teaching, became, and for long continued to be, the only written language of the country. But towards the end of the 18th century tendencies became apparent making for the displacement of Czech by Slovak. It was in the work of A. Beňolák (1762-1813) that these tendencies first assumed a concrete form. Additional impetus to the use of Slovak as a literary language was given by L. Štur (1815-56) and his followers, J. Kral (1822-74) and J. Botto (1829-81). The realists Sladkoví (1822-72) and Kalinčák (1822-71) were, however, the most remarkable writers of the period. Towards the close of the 19th century closer intellectual touch with the Czechs was resumed, one of the most prominent names connected with the movement being J. Vlček, whose history of Slovak literature is a standard work. The greatest poet of Slovakia is Hviezdoslav (Pavel Oszag, 1849-1921), and the best prose writers S. Hurban-Vajanský (b. 1847), who is also a distinguished lyric poet, and M. Kukučín, famous for his realistic stories of village life. The literary renaissance of the present day is associated in particular with the names of the two poets J. Jesenský and I. Kiško.

*Painting*.—The history of Czech painting begins with the illumination of manuscripts. In the 14th century, following the founding of an artistic brotherhood, a school arose in which Dutch and Italian influences were associated under the Hapsburgs. In the reign of Rudolf II. brilliant progress was made till interruption came with the Thirty Years' War. Between 1640 and 1674 Skreta was the leader of a revival of artistic activity; together with the religious decorator Brandl, and the painter Reinier, he is the forerunner of modern Czech painting. Under Josef II. all art fell into decay. But revival came in the 19th century with the awakening of national aspirations. Hellich, Lhota, Javůrek, Maixner, and Čermák combined to arouse interest in national art, but they were no more than imitators of the school of Düsseldorf, and it remained for the great artist Joseph Manes (1820-70), whose style varies from the classic and romantic to impressionism, to lay the logical foundations of a national school. Since Manes, artists of note have been M. Aleš (1849-1913), painter of Czech popular life, Brožík, historical painter, Knupfer, marine painter, Slavíček and Chitussi, landscape painters, Mucha and Hynais, decorative painters, Preisler and Švabinský, painters of portraits and allegorical subjects, Liška, painter of sombre pictures, and Boettinger and Strejti, painters of society and fashion. In Slovakia, Úpkra and his school have devoted themselves to representation of peasant life.

*Sculpture*.—The originator of Czech sculpture was Petr Parler, architect of the 14th-century cathedral of St Vitus. In Matthias Rejsek the

Renaissance produced another remarkable artist. In the 14th century the style of the Jesuits dominated. There followed a long period of decline, till in the 19th century Czech sculpture revived and developed along similar lines to Czech painting. Joseph Myslbek (b. 1848) is the great name, but Levý (1820-70), Max, Schnirch, Sucharda, Saloun, and Bílek are also important. Of more recent sculptors the chief are Štursa, Mařatka, Beneš, and Kafka.

**Architecture.**—Prague, the Florence of central Europe, is evidence in itself of the architectural genius of the Czechs. Czech architecture was first Roman, e.g. the basilica of St George at Prague, then Gothic, e.g. the magnificent cathedral of St Vitus, also at Prague. The 14th century saw the intrusion of the Jesuit style, and witnessed the triumph of baroque architecture. Under Ladislaus (1471-1516) flamboyant Gothic rose high in favour, revealing itself in Prague, in the churches of St Mary of Týn and St Charles, in the town hall, and in the towers of the Bridge of Charles IV. There followed in the 16th century an Italian period, when the Renaissance stamped itself everywhere. The 18th century brought a return to the baroque, while the 19th witnessed the restoration of old Gothic structures, and the erection of new buildings in neo-renaissance style; of new buildings the National Theatre at Prague is the crowning example. Both in the 19th and the 20th centuries Czech architecture came under the influence of the popular art of Moravia and Slovakia.

**Music.**—From 1348, the year of its foundation, music formed part of the curriculum of the university of Prague, while at a comparatively early date the subject was taught along with reading and writing in the elementary schools of Bohemia. In these circumstances the Czechs early gained fame as musicians. It is from the 19th century, however, that the period of great development dates. Chmelenský, Tovačovský, and Křižovský were forerunners, but Bedřich Smetana (1824-84), the creator of Czech opera, was the great figure. He was succeeded by Antonín Dvořák (1841-1904), whose compositions have become classics, by Fibich (1850-1900), and by Kovařovic. Among contemporary composers are Foerster, Novák, Ošeděl, and Suk, while exponents of note are Kubelík, Stěpán, Heřman, Kocian, Ševčík, and Ondříček. On Czech music the folk-songs of Slovakia have had a powerful influence, while within that country itself great musical progress has also recently been made, as reflected in the work of Janáček, Bella, Fügus-Bystřý, Schneider-Trnavský, and Moyzes.

**Science.**—The founding of the university of Prague in 1348 marks the real beginning of scientific activity among the Czechs. In the reign of Rudolf II. (1576-1612) Prague became a centre of science with which the names of Kepler, Tycho Brahe, &c., were associated. In mathematics, in medicine and surgery, and in exploration and geography, the Czechs were also distinguished, till decline set in with loss of independence in 1621. Restoration began with the mid-18th century. Purely scientific at first, emphasis came in the 19th century to be laid on the purely national aspects of learning. Landmarks in the revival were the founding of the 'Royal Learned Society' and the Bohemian Museum, and the establishment of the scientific periodicals, *Krok* in 1821, and *Ziva* in 1849, the first by J. S. Presl, who also created a Czech terminology for chemistry and other sciences; the second by J. E. Purkyně (1787-1869), a physiologist of European reputation. To this period also belongs Mendel (1822-84). In 1882 a fresh impetus was given to the scientific movement, when the university at Prague, Germanised from 1621,

was divided into two universities, one Czech, one German. Since then there have been few departments of science in which the Czechs have not risen to distinction.

**Czechs** (also spelt *Tzechs*, *Tschechs*, *Ceshs*, *Cheskians*, &c.). See CZECHOSLOVAKIA.

**Czegled**, a market-town of Hungary, 47 miles SE. of Budapest by rail. The inhabitants, 37,000 in number, follow principally agricultural pursuits, the district around yielding much grain and red wine.

**Czermak**, JOHANN NEPOMUK, physiologist, was born, 17th June 1828, in Prague; studied at Vienna, Breslau, and Würzburg; was professor successively at Cracow, Budapest, Jena, and Leipzig; and died 16th September 1873. He was the founder of laryngoscopy. His principal work is *Der Kehlkopfspiel* (2d ed. 1863), and his collected works were published in 1879.

**Czerno'witz** (Rumanian *Cernauti*), the capital of Bukovina, stands 720 feet above sea-level, near the right bank of the Pruth, 165 miles SE. of Lemberg by rail. Among its buildings are the palace of a Greek archbishop (1875); his cathedral (1864), on the model of St Isaac's at Petrograd; the Armenian church (1875); the synagogue (1877). The university was founded in 1875, refounded 1920. The manufactures and trade are steadily developing. The town changed hands repeatedly in the Great War. Pop. (1869) 33,884; (1910) 86,870; (1920) 90,000—Germans, Ruthenians, Rumanians, Poles, Jews, Armenians, and Gipsies.

**Czerny George**. See KARADJORDJE.

**Czerny**, KARL, pianoforte teacher and composer, born at Vienna in 1791, was the pupil and friend of Beethoven, and gained much from Clementi and Hummel. Besieged by pupils, he would teach only those of especial talent; among these were Liszt, Thalberg, and Döhler. Living in great retirement, he devoted much of his time to composition; a mass of MS. is preserved in the archives of Vienna; while his published works number over 900, of which his *Theoretical and Practical School* is the best known, and probably also the most valuable. He died 15th July 1857.

**Częstochowa** (Ger. *Tschenstochau*), or CZENSTOCHOWA, a town of Poland, 148 miles SW. of Warsaw by rail. A Catholic monastery, founded here about 1382, is visited yearly by fifty to sixty thousand pilgrims, as possessing the famous 'Black Virgin,' a murky painting of Byzantine origin, but ascribed by legend to St Luke himself. In 1655 the town was the only place in Poland which offered resistance to Charles Gustavus of Sweden, when 70 monks and 150 soldiers for 38 days held out against 10,000 men. The place has become the rival of Łódź for textile manufactures, and there is a great iron industry. Pop. 80,000.

# D

the fourth letter of our alphabet, descends from the fourth letter of the ancient Semitic alphabet, called in Hebrew *dāleth*, in Syriac *dōlath*; some early Semitic dialect had the name in a form which the Greeks adopted as *delta*. These forms are alterations of the Semitic word for 'door' (Assyrian *daltu*, Hebrew *dēleth*), and some have thought that the earliest known shape of the letter, Δ, represents the triangular 'door' (Gen. xviii. 2) or opening of a tent. It is unlikely that the inventors of the alphabet were tent-dwellers; but the doors of other kinds of habitation may have been triangular. In some early inscriptions the letter is written Δ; in the Aramaic variety of Semitic writing this character was opened at the top and erected, becoming 4, whence the Hebrew 7.

The Greeks adopted the letter in its original shape, which survives in the modern printed capital Δ. In some parts of the Hellenic world this form was altered to Δ, of which there was a rounded variant Δ. This was adopted by the Romans, who called the letter *dē*, on the analogy of their name for the second letter (see the article B). In rapid writing the letter was formed with a single stroke of the pen, and the curve continued backwards, producing the type Δ, whence, by rounding the outline, the Roman cursive Δ. A variant of this, with the upper stroke straightened, d, is found as early as the 1st century. All the various modern forms of the letter, script and printed, are recognisably derived from the Roman capital and cursive forms, with modifications adopted either for facility of writing or for ornament.

The normal phonetic value of the fourth letter, from the beginnings of the alphabet down to modern times, has (speaking generally) been the voiced stopped consonant produced by contact of the tip of the tongue with the roots of the teeth, the gums, or the portion of the palate behind the gums. This general description obviously leaves room for considerable diversity of articulation; thus the French *d*, which may be correctly described as dental, differs appreciably in formation and sound from the English *d*, for which the point of contact is farther back. In many languages this sound tends in certain positions to change into the corresponding open consonant (=th in *this*); and as this change was not always indicated in writing, the letter *d* or its equivalent acquired in such cases a second value. It is sounded as the open consonant in late Hebrew and Aramaic after vowels; in modern Greek in all positions except after *n*; in Spanish between vowels (at the end of a word *d* is sounded as the voiceless *th* in *thin*). In some languages, in which the letter at one time had both values, they were afterwards distinguished by diacritics or combinations of the letter; in pointed Hebrew and Aramaic the points show which sound is to be given; in Welsh the open consonant is expressed by *dd*; in Irish written in the native character the dotted S (in transliterated texts and in Scottish Gaelic rendered *dh*) had originally this value (the later pronunciation need

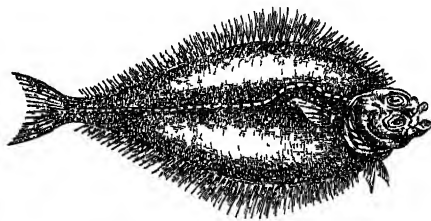

not be noticed here). In Old English the two sounds of our *th* (in *this*, *thin*), for which the Roman alphabet had no symbol, were expressed by *፥* (an altered form of *ð* = *d*), which was used indifferently with *p*. In Icelandic these symbols have been adopted, but with a phonetic distinction: *፥* = *th* in *this*, *p* = *th* in *thin*.

In some German dialects the sound of *d* differs from that of *t* only by having a less degree of force, both being alike voiceless. (Compare the article on B.)

In German, final *d* (preserved in spelling for historical reasons) is pronounced as *t*. The same unphonetic use occurs in English, in the past participles of verbs ending in voiceless consonants (as *miss*ed, *miss*'d), and rarely in French (as in *un grand honn*me).

D, in Music, is the second note in the natural scale. See MUSIC, SCALE.

**Dab** (*Pleuronectes limanda*), a species of Flounder (q.v.), common on European coasts, but not occurring in the Mediterranean. It is distinguishable from plaice and flounder by its light-brown or ashen-gray colour, with small irregular dark spots, by the roughness of its small, close-set scales, and by its more arched lateral line. Its length is from 8 to 16 inches. It is common all

Dab (*Pleuronectes limanda*).

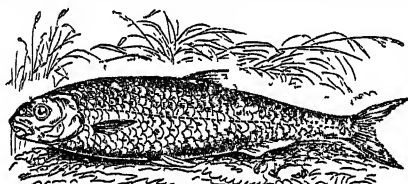

round Britain, and in the Firth of Forth is known as the Salt-water Fluke. Its flavour excels that of flounder. A rather larger species, of even more northern distribution, is the Lemon or Smooth Dab (*P. microcephalus*). It may be distinguished from the common dab by the fact that the first ray of the anal fin is not spiny. The brownish colour is sometimes prettily mottled.

**Dabchick.** See GREBE.

**Dacca**, a town of Bengal, on the Burhiganga, connecting the Ganges and the Brahmaputra, 150 miles NE. of Calcutta, consists of a dull esplanade and one long cross street, with a network of narrow, crooked lanes. Commanding the principal waterways of the delta, it was from about 1610 to 1704 (with an interval of twenty years) the seat of the Mohammedan government of Bengal. The suburbs extended 15 miles northward, where mosques and brick buildings are still found buried in thick jungle. In the 18th century it became widely celebrated for the delicate texture of its muslins, and the French, Dutch, and English had extensive establishments. In the 19th century, however, the change in the river system deprived it of its facilities for transit;

and this, with the competition of Manchester, almost completely ruined it. The population fell from 200,000 in 1800 to 69,212 in 1872. A small colony of muslin-weavers still survives, and other manufactures are coarse cotton cloth, embroidery, silver-work, shell-carving, and pottery. Besides Dacca University (founded 1921), there are many good schools, and a fine hospital; a system of water-works opened in 1878 improved the sanitary condition of the town. Pop. (1901) 90,542; (1911) 108,551; (1921) 119,450.—DACCRA DISTRICT has an area of 2777 sq. m., and consists of a level plain, intersected by a network of levees and artificial water-courses. Floods and droughts are never serious, but earthquakes are common. Food-crops, oil-seeds, jute, cotton, safflower, and sugar-cane are grown. Trade is carried on chiefly by water, and the rivers are crowded at all seasons with steamers and native craft; the adventurous boatmen of the district have a name throughout Bengal.

**Dace**, DARE, or DART (*Leuciscus vulgaris*), a fresh-water fish in the carp family Cyprinidae (q.v.), and of the same genus as the roach, chub, minnow, &c. It chiefly inhabits the deep and clear water of quiet streams. It is found in Italy, France, Germany, &c., and in some of the rivers of England, but is very local. In form it is not unlike the roach, but rather more elongated; the mouth is rather large, the scales smaller. The upper parts are dusky blue, becoming paler on the sides, and

Dace (*Leuciscus vulgaris*).

passing into white on the belly, the cheeks and gill-covers silvery white. It measures about 8 inches in length, and never exceeds a pound in weight. The dace is gregarious, and swims in shoals. It spawns in early summer. Its flesh is preferred to that of the roach, but is not highly esteemed. The dace is perhaps the liveliest and most active of the Cyprinidae, and affords the angler fair sport both with fly and bait.

**Dachshund**, a name adopted from the German, signifying 'badger-dog.' The dachshund has been common in Germany for many years, but was unknown in England until introduced by the Prince Consort towards the middle of the 19th century; it then became very fashionable and popular, but is not now so common. The dachshund is a small dog, weighing about 20 lb., with short crooked fore-legs, and an extremely long body, its head rather resembling that of a miniature bloodhound. Its strong, large paws enable it to dig rapidly. Its colour should be black and tan, or brown. On the Continent the dachshund is extensively used for covert-shooting, but rarely so in Britain, as his headstrong disposition somewhat spoils his usefulness. The dachshund is closely akin to the old English *Turn-spit*, employed to drive a wheel by which roasting-spits were turned.

**Dacia**, the land of the ancient Daci or Getae, including the country between the Danube, the Theiss, the Carpathians, and the Pruth. The Dacians were the most valiant of all the tribes of Thracian origin (see THRACE). In the reign of Augustus they began to molest the Roman allies, and indeed from this time there was almost continual fighting between the Romans and the Daci,

who actually, under their brave king, Decebalus, compelled their civilised enemies, in the reign of Domitian, to purchase peace by paying tribute. In 101 the Emperor Trajan crossed the Danube, and after five years' desperate fighting, conquered the whole country, and formed it into a Roman province. Roman colonists were sent into the country, great roads were opened up, and a bridge was built over the Danube—the ruins of which are still extant. Under Aurelian the Danube was made the boundary of the empire, and Dacia was resigned to the barbarians, its Roman colonies being transplanted to Mœsia.

**Dacier**, ANDRÉ, a French scholar, born of Protestant parents at Castres, in Upper Languedoc, 6th April 1651, studied at Saumur under Tanneguy Lefebvre; and in 1672 came to Paris, where in 1683 he married Anna (1654–1720), his old preceptor's daughter, and two years later was admitted with her to the Roman Catholic Church. Dacier subsequently became royal librarian, member of the Academy of Inscriptions and of the French Academy, and perpetual secretary of the latter. He died 18th September 1722. His works include a Delphin edition of Festus and Verrius Flaccus (1681), as well as indifferent translations of Horace, the *Poetics* of Aristotle, some of the Dialogues of Plato, Epictetus, and Plutarch's *Lives*. His wife's works include Delphin editions of Florus, Aurelius Victor, Eutropius, Dictys Cretensis, and Dares Phrygius; and translations of Anacreon, Sappho, some plays of Plautus and Aristophanes, Terence, the *Iliad* and the *Odyssey*. Her admiration of Homer was more unbounded than discriminating, and involved her in many controversies.

**Dacoits**, or DAKAITS, a name used for brigands herding in gangs in various parts of India, and living by *dakaiti* or robbery with violence, long specially the curse of Central India. The annexation of Burma in 1885 increased for a time the labours of the Thaggy and Dakaiti Department, but systematic dakaiti, which in the later decades of the 19th century had still some 9000 representatives, has steadily been suppressed. Like the Thugs (q.v.), the Dakaits proper recognised specific religious sanctions. See HERVEY, *Some Records of Crime* (1892), and books named at BURMA.

**Da Costa**, ISAAC, a Dutch poet, born at Amsterdam, the son of a Portuguese Jew, 14th January 1798. He studied at Leyden; and in 1822, a year after receiving the degree of doctor of philosophy, he embraced Christianity. His poems speedily gained him such reputation that, on the death in 1831 of Bilderdijk, whose warm friendship he had enjoyed, Da Costa succeeded him in the first place among the poets of Holland, which he held till his death, on 28th April 1860. His principal works are to be found in his *Poezij* (2 vols. 1821–22), *Politieke Poezij* (1854), and *Hesperiden* (1855). His *Battle of Neupoort*, the last of his poems, is one of his masterpieces. Da Costa also made essays in the domain of history and theology, the most important of which, *Israel and the Gentiles*, was translated into English.

**Dacotahs**, or DAKOTAS, a branch of the Sioux Indians. See SIOUX.

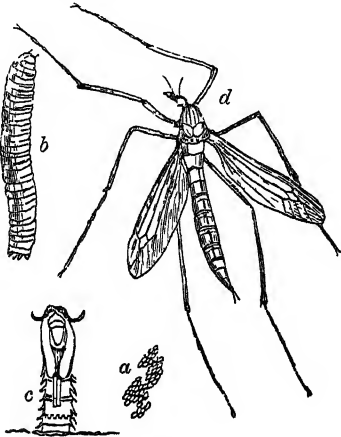

**Dacrydium**, a genus of coniferous trees of the yew family, but more allied to Podocarpus. There are twelve species—Malayan, Tasmanian, and of New Zealand. *Dacrydium cupressinum* of New Zealand is best known in Britain, on account of the beauty of its pendulous foliage. *D. franklinii*, the so-called Huon Pine, and *D. taxifolium*, the Kakaterata tree, yield valuable timber.

**Dactyl** (Gr. *dactylos*, 'finger'), the name of a measure or 'foot' in Greek and Latin versifica-

tion, consisting of a long and two short syllables, as in the word *omnibits*. It was so called from its resemblance to the finger, which consists of three joints—one long and two short. The same name is sometimes applied to a trisyllabic measure in English verse, consisting of one accented syllable and two unaccented syllables, as in *destiny* (see VERSE). Dactylic verse consists of dactyls and spondees, and includes both hexameter and pentameter verse.

**Dactylogy**, the art of communicating thoughts by the fingers. See DEAF AND DUMB.

**Daddy-long-legs**, or CRANE-FLY (*Tipula oleracea*), a familiar insect in the order Diptera, and a good type of its family Tipulidæ. The body, the legs, and the antennæ are very long. The latter have an arched curvature, and are longer in the males; the front of the head projects prominently; the posterior body, which is connected with

Daddy-long-legs (*Tipula oleracea*):

a, eggs; b, larva; c, pupa case as left by the insect sticking out of the earth; d, perfect insect.

the thorax by a very thin bridge, is broader in the females. The middle of the body is gray, with brown stripes, the abdomen reddish-brown, the legs brownish-yellow, and in part blackish, the wings brown, varying to red and white. This common European insect is towards an inch in length, is abundant from July to October in meadows and gardens, and is familiar to every one. The female is often seen laying her numerous eggs in damp places on the ground; the eggs are small, black, and shining; the larvæ, known as 'leather-jackets,' live in the ground, and often do damage in vegetable gardens and fields; the pupæ have spines on their abdominal segments, by which they push their way out of the ground. Of the genus *Tipula* about ninety European species are known. The largest form (*T. gigantea*) measures over an inch, and is not uncommon in Britain. *T. hortulana* is very common in gardens. The genus *Ctenophora*, commoner in wooded districts, is nearly allied. They have stouter bodies, and usually brighter colours. See GNAT, MIDGE.

**Dado** (Ital., 'a die'), in classical Architecture, the term applied to the cubic block which forms the body of a pedestal. It is also applied to the plane face and the series of mouldings which, in the interiors of buildings, form, as it were, a continuous pedestal. The interior dado is formed of wood, and, running round the bottom of the walls of a room, serves to protect the plaster or paper from injury. Dados and wall-linings were much used in Elizabethan and subsequent styles till the 19th century, when under the classic regime, they

were dispensed with. The revival of the 'Queen Anne' taste, however, led to the reintroduction of dados not only in the form of wooden panelings, but also in the painting and papering of the walls.

**Dædalus**, a figure in Greek Mythology who personified the beginning of the arts of sculpture and architecture. He was of the old Athenian royal race of the Erechtheidæ. Having killed his nephew and pupil in envy at his growing skill, he had to flee to Crete, where he made the well-known cow for Queen Pasiphaë, and afterwards for King Minos the famous labyrinth to confine the Minotaur. Minos next imprisoned Dædalus, but he escaped with the help of Pasiphaë, and formed wings for himself and his son Icarus, with which to fly across the sea. He himself flew safe across the Ægean, but unhappily Icarus flew too near the sun, the heat of which melted the wax that fastened his wings to him, so that he dropped into the sea, and left his name to be borne by that part of the Ægean into which he fell. Dædalus made his way to Sicily. Some accounts made him first alight at Cumæ in Italy, where he dedicated his wings to Apollo. Works of art were freely ascribed to Dædalus in Greece, Italy, Libya, and the Mediterranean islands. The name *Dædala* was applied to the earlier painted and gilded wooden statues of the gods.

**Daendels**, HERMAN WILLEM, a great Dutch general, was born in 1762 at Hattem, in Gelderland, took part in the revolutionary disturbances that broke out in Holland in 1787, and was in consequence compelled to seek refuge in France. In the campaign of 1793 he rendered important service to Dumouriez, and was elevated to the rank of a general of brigade. In 1799 he commanded one of the two divisions of the army of the Batavian republic, and in 1806 took service under the king of Holland. From 1808 to 1811 he was governor-general of the Dutch East Indian possessions, and published a work on them. On the overthrow of Napoleon, the new king of Holland, William I., intrusted Daendels with the organisation of the Dutch colonies on the coast of Africa, and there he died in June 1818.

**Daffodil** (corrupted from Lat. *asphodelus*), the English name of those species of *Narcissus* which have a large bell-shaped corona. The Common Daffodil (*N. pseudo-narcissus*) is a native of England and of most parts of Europe, growing in woods and hedges, and often cultivated in gardens, where it not unfrequently becomes double. It is naturalised in many places in Scotland and Ireland, but seems scarcely indigenous. From Herriek's lament to Wordsworth's dancing verse we have widely varied recognitions of the familiar golden cups of the daffodil as a source alike of poetic wealth and inspiration. See NARCISSUS.

**Dafydd ab Gwilym**. See GWILYM.

**Dag**, a thick pistol, of the 15th and 16th centuries. The word sometimes means a dagger.

Common Daffodil  
(*Narcissus pseudo-narcissus*).

**Dagger**, a weapon resembling a sword, but considerably smaller, being used for stabbing at close quarters. Daggers are generally two-edged, and very sharp towards the point. The *dagger of lath* was the Vice's weapon in the old moralities.

**Daghestan** ('mountain-land'), a triangular territory of Ciscaucasia, between the Caucasus and the west coast of the Caspian Sea, was by decree of the Moscow government in 1921 made a republic in federation with Russia. Area, 14,000 sq. m.; pop. 800,000. The surface is generally mountainous, being traversed by offsets from the Caucasus; the level tracts are chiefly near the coast, and here and in the valleys the land is very fertile. The country is well watered, the climate generally mild in the lowlands, and dry, except along the coast, where the rainfall is considerable. In the highlands large flocks of sheep are herded. The capital is Derbend (q.v.). See CAUCASUS, and SHAMYL.

**Dagö** (Hiiumaa), an island near the entrance of the Gulf of Finland, forming part of Esthonia, and separated by the narrow channel called Selsund from the island of Oesel on the south. Area, 367 sq. m. The inhabitants include many Swedes and Germans. The coast is rugged, and the soil fertile only in the south and south-west; inland there are large forests and swamps (54 sq. m.).

**Dago**, an American slang name for a Spaniard, Portuguese, or Italian (perh. from Sp. *Diego*, 'James').

**Dagoba**, the common name in Ceylon for a Buddhist Tope (q.v.).

**Dagobert** was the name of several of the Merovingian kings of France, the first of the name reigning from 631 to 638. See FRANCE.

**Dagon**, the national god of the Philistines, half-man, half-fish, is mentioned in the Old Testament as having temples at Gaza and Ashdod. There is evidence that Dagon was worshipped too in Phœnicia and some districts of south Palestine. He seems to have come to Canaan from Babylonia, the Assyrian monuments presenting a figure with the body of a man and the tail of a fish, and the cuneiform inscriptions containing the name of a god *Dakan* or *Dagan*, which is probably identical with Dagon. Most scholars favour the old derivation of the name from *dag* ('fish'); but others, following Philo Byblius, connect it with the word *dagan* ('corn'), and regard Dagon as the god of agriculture.

**Daguerreotype** is the name of the photographs fixed on a plate of copper thinly coated with silver by the successive action of the vapours of iodine, bromine, and mercury. Louis Daguerre, after whom the invention is named, was born in Normandy in 1789, was a scene-painter in Paris, made a famous diorama in 1822, and devoted the rest of his life mainly to perfecting the processes of photography, from 1826 till 1833 in conjunction with M. Niepce. He wrote two works on the subject, and died in the neighbourhood of Paris, 12th July 1851. The history of the invention is given at PHOTOGRAPHY.

**Dahabiyah**, a boat used by voyagers on the Nile, which varies in size, has one or two masts, and accommodation for from two to eight passengers, including a raised cabin on the after-deck. The boat sails, is rowed, or is dragged by ropes, according to circumstances.

**Dahl**, JOHANN CHRISTIAN CLAUSEN, a Norwegian landscape-painter (1788-1857), born at Bergen, from 1821 onward was professor of Painting at Dresden.

**Dahlak**, a group of three islands, with many smaller rocks, in the Red Sea, off the Bay of Massowah. They were famous in Roman times for their pearl-fisheries, which have been revived

in modern times. The inhabitants carry on a trade with the Arabian coast. The islands form part of the Italian colony of Eritrea.

**Dahlgren**, FREDRIK AUGUST (1816-95), Swedish poet, wrote many popular dialect songs and ballads, and some successful dramas.

**Dahlgren**, JOHN ADOLF (1809-70), born in Philadelphia of Swedish parents, served in the U.S. navy, being attached after 1844 to the ordnance department. In 1850 he invented the muzzle-loading, smooth-bore, cast-iron gun, called after him, which, strengthened by wrought-iron cores or coils, remained in use in the navy till 1880-85.—His wife, SARAH MADELINE VINTON DAHLGREN (1835-98), wrote many poems and sketches.

**Dahlgren**, KARL FREDRIK (1791-1844), Swedish poet, born at Stensbruk in Östergötland, studied at Uppsala, and from 1815 was a preacher at Stockholm. One of the best Swedish humourists, he published songs, odes, a satire, a comedy, idyls, and a novel, and edited a literary annual.

**Dahlia** (*Dahlia variabilis*, &c.)—after Dahl, a Swedish botanist, and pupil of Linnæus—a genus of large perennial composites (sub-order Tubulifloræ, family Helianthææ). It was first brought from the botanic garden of Mexico to that of Madrid in 1784, whence it reached England in

Dahlia :  
A, single; B, double varieties.

1789, and France in 1802, while in 1804 Humboldt sent a fresh supply of seed to Berlin. Its extraordinary variability soon attracted the attention of florists, who brought to bear on it all the resources of selection and crossing, with so much success that by about the middle of the 19th century no fewer than 2000 varieties had been described, all from *D. variabilis* or *D. coccinea* or their hybrids, and chiefly from the first named. For a long time only 'double' dahlias were cultivated, but of late years the single dahlia, in which the florets of the disc remain tubular, has again come into fashion; while among double dahlias the less regular cactus dahlia is highly esteemed. They are easily cultivated, and propagated by seeds, cuttings, or tubers; but the tubers may require to be taken up and stored in a dry place out of the reach of frost. They flower luxuriantly in autumn, until cut off by the first frosts. On account of the quantity of inulin in their tubers, they are cultivated for food in Mexico, but similar attempts in Europe have failed

because of their unpalatableness. See Nicholson's or other *Dictionary of Gardening*, also any florist's catalogue.

**Dahlmann**, FRIEDRICH CHRISTOPH, German historian, was born May 13, 1785, at Wismar. His earlier studies in Copenhagen and Halle were devoted to archæology and philology; but his attention was subsequently directed to the study of politics and the history of the middle ages. From 1813 on, he filled the chair of History at Kiel, and in 1829 was appointed to that of Political Science in Göttingen, where he published (1830) his invaluable *Quellenkunde der deutschen Geschichte*. Banished in 1837 by King Ernst August of Hanover, on account of his protest against the abolition of the Hanoverian constitution, he went to Leipzig, next to Jena, where he wrote his historical masterpiece, *Geschichte von Danemark* (3 vols. 1840-43). In 1842 he became Professor of History at Bonn, and took a prominent part in the political affairs of Germany after the movement in 1848, heading the constitutional liberals, who were unfortunately too reasonable to be successful. At the close of the struggle, he returned to his academic duties, to which he devoted himself till his death, 5th December 1860. See *Life* by A. Springer (2 vols. Leip. 1870-72).

**Dahn**, JULIUS SOPHUS FELIX, publicist, historian, and poet, was born at Hamburg, 9th February 1834, the son of a well-known actor and actress. He studied law, philosophy, and history at Munich and Berlin, became extraordinary professor at Munich (1862), next year ordinary professor at Würzburg, in 1872 professor of German Jurisprudence at Königsberg, and in 1888 at Breslau. Amongst his contributions to public law are *Das Kriegerrecht* (1870), *Handelsrechtliche Vorträge* (1875), *Deutsches Rechtsbuch* (1877), and *Deutsches Privatrecht* (1878). Of his historical works the chief are *Prokopius von Casarea* (1865), *Die Könige der Germanen* (1861-1908), *Westgotische Studien* (1874), *Langobardische Studien* (1876), *Urgeschichte der germanischen und romanischen Völker* (3 vols. 1881-90), and *Geschichte der deutschen Urzeit* (1885). He died 3d January 1912. His versatility is remarkable; he wrote also a series of popular historical romances, and of lyrical and dramatic poems. Of the former may here be named *Ein Kampf um Rom* (1876), a powerful novel, *Odhins Trost* (1880), and *Die Kreuzfahrer* (1885). See his *Erinnerungen* (1892-93).

**Dahna**. See ARABIA.

**Dahomey** (the native name of the people being *Dawma* or *Dahomé*) is since 1892-94 a French protectorate in Western Africa, between Lagos (British) and Togoland, with an area stated at 40,000 miles. The frontiers of the 'hinterland,' always vague, were matters of disagreement and debate, but were finally settled by the Franco-German convention of 1897 and the Anglo-French convention of 1898; and in 1907 about 24,000 sq. m. in the north-west were transferred from Dahomey to the French colony of Upper Senegal and Niger. The long lagoon which, shut in from the ocean by a protecting bank of sand, affords an easy route along nearly the whole of this coast, extends in Dahomey, from its western frontier almost to the Denham lagoon, in the east. About midway is the port of Whydah, whence a road extends inland to Abomey, a distance of 65 miles. Dense forests and dismal swamps cover nearly two-thirds of this distance, but from the Great Swamp of Agrimé vast undulating plains rise for many miles, in the direction of the Kong Mountains. The Avon and Denham lagoons receive the rivers of the country, none of which are very important. The soil is a rich, red-coloured clay, and is extremely fertile.

Groves of oil-palms encircle each town, and palm-oil is made in large quantities. Maize, beans, and peas, as well as cassava, yams, sweet potatoes, limes, oranges, pine-apples, and other tropical fruits, grow luxuriantly; cotton, sugar, and spices are also grown. Cotton cloth is made, and weapons and tools are forged from native iron.

The people are negroes, of the Ewe group, generally of small stature, but very robust and active. The Dahoman kingdom dates from the beginning of the 18th century, and reached its zenith under Gezo, who ruled from about 1818 to 1858. An army of about 10,000 existed, 1000 of whom were Amazons (devoted to celibacy), who were distinguished for their bravery and ferocity. Fetish-worship prevailed, taking the form of serpent-worship along the coast. The king was the most absolute of despots, and wholesale murder was one of the chief features in religious and state ceremonies, as many as 500 human victims having been sacrificed at one of the grand 'customs' which took place annually. The revenue formerly depended greatly upon the sale of slaves. In 1876 the coast of Dahomey was placed under a strict blockade by Great Britain, on account of an outrage on a British subject. In 1892 a French expedition under Colonel Dodds, after several victorious engagements, took Cana and dictated terms to King Behanzin in his capital. The French established a footing on the coast in 1851, and gradually extended their influence till, in 1894, the whole kingdom was taken in. The colony comprises, besides the native kingdom of Dahomey, all the French possessions bounded on the north by the French colonies of Upper Volta and of the Niger, on the east by British Nigeria, on the south by the Gulf of Guinea, and on the west by Togoland. Pop. 842,000. There are about 70 miles of coast. The chief port is Kotonu, terminus of a railway to the Niger. The French capital is Porto Novo (pop. 20,000). Other centres are Abomey, the former capital; Allada; Agone; Grand Popo; Whydah (Ouidah), a port; and Nikki. The chief exports are palm kernels and oil. Steamers ply along the coast lagoons, and Kotonu is in communication with Europe. The foreign trade is chiefly British. The colony has its own budget, and is self-supporting. It is under the governor-general of French West Africa.

See works by Burton (new ed. 1864), Skertchly (1874), Bouche (Paris, 1885), and Aubley (Paris, 1894); Ellis, *The Ewe-Speaking Peoples* (1890); and the British Foreign Office handbook *Dahomey* (1920).

**Dahra**, a district of Algeria, to the east of Mostaganem. In June 1845 Pélissier (q.v.) suffocated 500 refugee Kabyles in caves here.

**Dáil Eireann**. See IRELAND (*Government, History*).

**Daimiel**, a town of Spain, 28 miles ENE. of Ciudad Real by rail, with manufactures of woollens, brandy, &c.; pop. 16,000.

**Daimler Motor**, a specially modified petroleum oil-engine (see INTERNAL-COMBUSTION ENGINE, MOTOR-CARS), perfected by the inventor, Gottlieb Daimler of Cannstatt (who assisted Otto of Deutz in perfecting his gas-engine), for use in automobiles. Such carriages could, even when, noisy and smelly, they were first put upon the roads, easily do twelve and a half miles an hour, and carry supplies of petroleum for four or more hours' running.—Daimler (1834-1900) was born at Schorndorf, and took charge of the Deutz factory in 1872. The Daimler Motor Company was founded in Cannstatt in 1890, with subsequent headquarters in Untertürkheim and Berlin.

**Daimyos**, the old nobles of Japan (q.v.).

**Dairen**, or TAIREN (Russian *Dalny*, Chinese

*Ta-lien-wan*), a great port of Manchuria on the SE. coast of the Liao-tung peninsula, 20 miles ENE of Port Arthur, created by Russia in the last years of the 19th century as one of the Pacific termini of the Trans-Siberian railway. The deep and spacious harbour is ice-free throughout the year. Early in the Russo-Japanese war (May 1904) Dairen was occupied by the Japanese, who declared it a free port. It is the seat of administration of the Japanese leased territory. It exports soy beans, bean products (oil-cake, fertilisers, &c.), wild silk-cocons, and silk thread. Pop. 50,000.

**Dairy** is a word derived from the old *dæge*, *dase*, *dey*, or *deye*, a maid-servant or dairymaid. The dairy or milk-house of a farm should be an entirely detached structure to avoid contamination from cow-house, stable, or other farm buildings. A free current of air in the dairy must be arranged for by a careful system of ventilation. In order to facilitate the washing of the building the walls should be of glazed brick and the floor of cement, with all internal drains in the form of open channels. A butter-dairy is best divided into three compartments—a separating and butter-making room, a cream-ripening room, and a scullery or covered yard for washing milk-cans and other utensils. The first essential in a dairy is the absolute cleanliness not only of the floors and walls of the building, but of all its furnishings. This is secured by daily washing and by the scalding or steaming of all vessels or implements which come in contact with milk or its products. The thermometer in the dairy should stand at 55° F. in summer, and 60° F. in winter. At temperatures higher than these milk is liable to spoil, owing to the greater activity of the microbes in it; many degrees below this it gets chilled, and will not manipulate satisfactorily. An abundant supply of pure water is necessary, and means for boiling water must also be provided, not only to secure scalding water for washing, but to raise, when necessary, the temperature of the products of milk during manufacture, or maintain a suitably high temperature in the air of the cheese-room or the milk-house. A small steam or gas engine is frequently employed in a dairy conducted on a large scale to supply the power necessary for a centrifugal cream-separator, also for churning whole milk or cream.

*Dairying* has developed much within recent years. The growing demand for milk in large towns has increased the volume of the milk-trade, and modified the system of management. Summer dairying, while suitable for the making of cheese, and so far for butter also, must be supplemented by winter dairying to keep up the supply of milk and fresh butter throughout the year. For summer dairying it is usually arranged that the cows calve during March, April, and May, so that they go to pasture when they are coming to the period at which, with a proper supply of succulent food and suitable surroundings, they should develop their greatest yield of milk. They lie out day and night, and have the whole summer and early autumn before them—the period in which grass, the natural food of a cow, is most abundant, best, and cheapest. In some instances the grass is supplemented by 2 or 3 lb. a day of cotton-seed or other cake, and when the grass begins to fail in autumn, some variety of green food, as cabbages, rape, vetches, &c. As frost begins to appear the cows are housed at night, and in spite of liberal and careful feeding, fall off in their yield of milk. Nevertheless it is the better practice to house them in good time, because they keep in better condition during winter than if left out too long, and for the few remaining weeks of the milking period they give a larger average return. All naturally 'dry off,' some more rapidly than others; and milking should be stopped at the end of the

year. After two or three months of rest the cows calve, and this goes on year by year from the age of two or three (depending upon size and condition) until they are ten years old, when all should, without exception, be replaced by heifers. This class of dairy-farming is now only found on cheese-farms where distance from town or station renders the daily sale of milk or butter impossible.

Where winter dairying is practised the cows are so managed as to calve in rotation, and thus keep up a constant supply of milk throughout the year. With the introduction of winter dairying the practice of keeping cows entirely housed day and night came into vogue. As this affected the constitutions of the cows, they were only kept during one period of lactation and then sold. The building up of a good milking herd by the selection of calves from the best milkers was under this system impossible, and it has therefore disappeared, except where cows are kept in towns. In country dairies the cows live entirely in the open during the summer, and are also turned out for a part of each day during the winter months. In order to force the milk-yield in winter the temperature of the cow-houses was kept high, which resulted in an increase in bovine tuberculosis; now sanitary regulations demand an air-space of 600 cubic feet per cow in country districts and 800 cubic feet in towns, with a free current of air by ventilation.

Eight to ten cows is a sufficient number for each milker, and the operation should be performed as quietly and as expeditiously as possible. Men are usually employed in England, and women in Scotland. Efficient milking-machines can now be purchased, and the proper cleaning of these, which was originally a difficult matter, has been rendered easy by simplification of parts. They effect a great saving in wages paid to milkers, and are an especial boon where labour is not easily obtained. The initial cost of a milking-machine, with necessary engine and vacuum-pump, precludes its use in dairies of under twenty cows. When cows give a large flow of milk, or when it is wanted for town consumption, milking is done thrice daily; but in the great majority of cases throughout the country it is only performed morning and evening. Heavy milking cows consume a large quantity of water, which should be supplied to them at least twice daily. Cows consuming a large amount of sloppy food and roots do not require much water.

It is important that the water should be pure and clean. Outbreaks of typhoid fever among children have been traced to cows drinking water contaminated with the germs of this disease, which was communicated to children who drank the milk. No injurious results have been traced to the use of sewage irrigation grass, which has been largely superseded by Italian ryegrass. In some parts clover and vetches take the place of ryegrass. Succulent food is essential for the production of large returns of milk. As the grass season ends in October, the succulent portion of food may be derived from brewers' and distillers' grains (1 bushel per day being a full allowance for a large cow), and from turnips. Turnips, when given in excessive quantities, produce an objectionable taste in the milk and butter; but as an ingredient in a liberal and well-balanced diet they may be used with impunity where milk is the product wanted. Swedes and mangels are not so liable as common turnips to taint cow products. Cows in full milk require a daily allowance of perhaps 5 to 8 lb. of concentrated food—a mixture of various farinaceous meals and oil-seed cakes along with bran, which acts as a corrective as well as a food substance. Bean meal is prominent among the meals for encouraging a flow of rich milk and at the same time maintaining the condition of the cow. Turnips, unless liberally supplemented, are

apt to reduce the condition. There is a decided advantage in giving a mixed food, as compared with one variety, provided a proper proportion is secured between the albuminoids and the carbohydrates—one to five is a good average to aim at under ordinary circumstances, having estimated oil as equivalent to two and a half times its weight of starch. Not only must the proportion of the components of a food mixture be adjusted, but the total bulk of the food must be great enough to distend the stomach sufficiently to promote healthy action in the digestive system. About 30 lb. of dry food substance is a good allowance for a healthy milking cow of one of our large breeds. If that were given entirely in the form of concentrated food, such as meal and cake, the animal could not chew the cud, and impaction of the rumen would result. The practice of chaffing straw into very short lengths is associated with the same danger. Dry fodder, more especially straw, is vastly improved for milk cows by cooking—either steaming it, or throwing warm water over it, and covering it up for a few hours. In spring, before the grass comes, the flow of milk in newly calved cows is often largely developed and maintained by treating hay in this fashion. When very large quantities of concentrated food are used, it is safer to add to the daily allowance of each cow from 1 to 2 lb. of treacle, which not only supplies a valuable ingredient of food, but is also beneficial as a laxative. Epsom salts should never be given to a cow in milk; where an aperient is required, it is safer to give 8 to 10 lb. of warm treacle. Bought concentrated food has another function than the above to perform; its ash ingredients, which pass away in the manure, make good to the land the considerable loss of phosphate and other valuable substances which are removed in dairy products—more especially milk. Education in dairy husbandry and practice holds an important place in the curriculum of the various agricultural colleges in Britain, the United States, and the dominions, and in Britain and elsewhere there are numerous dairy schools.

The Contagious Diseases (Animals) Acts (q.v.) and other acts allow the Ministry of Health and the Scottish Board of Health to make special orders for the purpose of procuring supplies of pure and healthy milk. The registration of all cowkeepers, dairymen, and purveyors of milk is required, and their premises must be open to inspection. The authorities, through an inspector, can enforce rules regarding the necessary lighting, ventilation, and water-supply of dairy buildings. It is also required that cowsheds be properly cleansed by limewashing the walls and ceiling at least twice a year. No person suffering from an infectious disease may milk cows or handle vessels used to contain milk for sale. Buildings converted for use as dairies or cowsheds, or new buildings erected for that purpose, must be passed by the local authority before being occupied. Under the Food and Drugs Act, 1899, the Board of Agriculture made certain regulations known as the Sale of Milk Regulations, 1901, by which milk containing less than 3 per cent. butter-fat and 8·5 per cent. solids other than fat was regarded as adulterated. The Public Health Act, 1907, and later acts control the use of preservatives in milk, as the excessive use of some of these is injurious, especially to children.

The principal breeds of Cattle (q.v.) used in the British Isles for dairy purposes are as follows: Dairy Shorthorns, Jerseys, Guernseys, Devons, and Red Polls in England; Ayrshires in Scotland and north of England; Kerrys in Ireland; and a few other breeds confined to small districts. The Channel Islands breeds are especially suitable for the production of butter, as the fat globules in their

milk are large, and therefore separate easily from the liquid. Ayrshire cattle give milk best suited for the manufacture of cheese, as the fat globules are small and do not readily rise to the surface. There are two types of Shorthorn, the first having been bred by selection with a view to producing a good beef animal; whilst the milking properties of the second class have been the aim of the breeder. This dairy Shorthorn is an excellent combination of qualities for general dairy purposes, and is the breed most extensively distributed throughout England.

Dairying on the factory system is carried on in the United States, chiefly in New York, Wisconsin, Iowa, Ohio, Pennsylvania, Illinois, Vermont, Minnesota, Michigan, and Kansas. The cattle used are chiefly imported breeds—Dutch or Holstein, Channel Islands, Ayrshire, and Brown Swiss. Cows which have been produced by crossing the native cattle with imported bulls are known as 'grade' Shorthorns, 'grade' Jerseys, &c. The 'grade' Shorthorns are fairly numerous, although the pure breed is not popular in America for dairying, as the specimens introduced to that country were rather of the beef type. The methods of feeding dairy stock in America are similar to those in use in Britain; but for winter-feeding, turnips and the various meals are replaced by maize silage and ground maize, while the hay is largely made from alfalfa or lucerne (*Medicago sativa*). The governments in the various states have brought into force stringent sanitary regulations.

In Canada the dairy industry is carried on extensively in many provinces, and it is from this country that Britain mainly draws her imports of cheese, this article being chiefly of the type known as 'Canadian Cheddar.' Ontario, especially in the eastern parts, is the province which supplies the bulk of the cheese exported from Canada; whilst in Quebec butter is the chief dairy product. In southern New Brunswick dairying is on the increase; and other provinces where this type of farming is found to considerable extent are British Columbia, Manitoba, Alberta, Nova Scotia, Prince Edward Island, and Saskatchewan. The conditions of dairying in Canada have shown marked improvement since the appointment of a Dairy Commission in 1890. The government, by opening and staffing with officials several factories and creameries, did much to further the adoption of this system. The factories thus started were afterwards bought up by members of co-operative societies, who still had access to advice from government experts. A service of trains, equipped with facilities for cold-storage transit, was also arranged, and this proved of great benefit for the removal of produce to the towns and for export. The most popular breeds of cattle on dairy-farms in the Dominion are Holstein, Ayrshire, and Jersey; whilst the Shorthorns are also numerous, being more in favour than in America. As in America, maize silage and alfalfa hay are foods largely in use for dairy stock.

New Zealand has the reputation of sending the best class of butter to Great Britain, the quality being sufficiently high to enable it to compete with the Danish butter, which formerly brought the highest price of any imported. Originally the difficulty of obtaining labour checked the spread of the dairy industry; but the introduction of efficient modern milking-machines has led the colonists to convert sheep-runs into pasturage for dairy herds. The co-operative system is largely adopted in New Zealand for the manufacture of butter and cheese, and the establishments producing the former are greatly in the majority. All butter for export is carefully graded by government officials. The crops grown for the winter-feeding of dairy stock are

much the same as those in use in Great Britain, but the American system of growing maize for silage is rapidly increasing in popularity. The usual pure breeds are Dairy Shorthorn, Ayrshire, Holstein, and Kerry; whilst large numbers of crosses between Shorthorn and Ayrshire blood are found on many farms.

The industry of dairying in Australia is carried on chiefly in the states of Victoria, New South Wales, Southern Queensland, and South Australia, and the exports are chiefly composed of butter, with cheese forming a small part. Australia uses the co-operative system, and all butter so produced is government graded, although the Australian article hardly enjoys so high a reputation as that of New Zealand. The Shorthorn is the principal dairy breed, but Ayrshires, Kerrys, and of late years Holsteins have been imported, and crosses between these various strains made with considerable success. The establishment of State experimental and advisory stations has led to the improvement of the natural pastures by the introduction of the seeds of more valuable grasses. The feeding of stock on ensilage during the dry season is becoming common.

In South Africa dairying has as yet not been practised to any great extent, owing to the fact that the native cattle were better suited to beef production, and the efforts of breeders went to improve the animals in this direction. The importation and use in crossing of Dutch cattle gave rise to a general-purpose cow, which was used as a milk-producer. Pure herds of Ayrshires and Jerseys are now found in Cape Province, and the bulls have been used for crossing purposes with benefit to the stock of the district. The Transvaal has imported pure strains of British dairy stock to its experimental farms, whence farmers procure good bulls to improve their stock.

DAIRY FACTORIES originated in the Jura districts of France and Switzerland, but first came into prominence in America. The first American factory was organised in New York state by Jesse Williams in 1860, being for the production of cheese only. The result of the system was so favourable with regard to the uniformity of quality and increased market value that the number of factories increased rapidly in other states and in the Dominion of Canada. The cheese produced in these factories is made on an adaptation of the Cheddar system (see CHEESE), and quickly took a high position in the markets of England and other European countries, being known as 'Standard American' or 'American Cheddar.' The production of butter on the co-operative principle in the States began at a later date, the name creamery being used to distinguish such institutions from the factories producing cheese. The method of dealing with milk in factories spread from America to Denmark, Sweden, and Holland, where its introduction was attended with excellent results. The first cheese factory in England was established in Derby in 1871, and in the same year a new building modelled on those existing in America was erected on the estate of the Hon. E. W. Coke at Longford, Derbyshire. Subsequent institutions have been organised on lines copied from the factories of America and Denmark, which countries have been visited by deputations, and reports issued.

Co-operative dairies may have as their object the selling of milk, the production and sale of butter, or the manufacture of cheese. The last, however, are not increasing to any great extent in England. In forming a co-operative dairy for any of the three above-named purposes, the farmers supplying milk are usually shareholders to the extent of at least £1, but proprietary factories are also found which purchase milk from the farmer, who has no further interest in the business. The

members of a co-operative factory of the milk-selling variety appoint a manager; they receive payment as their milk is delivered, and also participate in the profits of the factory. On becoming shareholders they voluntarily bind themselves under stringent regulations to produce and place on the market milk which is above suspicion. Inspectors from the factory make periodical visits to the farms in the combine, and it is therefore almost impossible for a farmer to supply milk from unhealthy cows, to make use of improper cow-houses, or to carry on the milking without due attention to cleanliness. The presence of an infectious disease in a farm-house from which milk is supplied to a factory is notifiable, and no milk is delivered until the buildings are pronounced free from infection. These precautions are of great benefit to consumers, who are certain of obtaining milk of excellent quality, for which they are willing to pay a slightly increased rate. The advantage to the farmer lies in obtaining a higher price, both on account of the high standard of quality and the factory being in a position to control the market owing to the large output. The milk on arrival at the factory is filtered through sterilised cotton, and cooled to 40° F.; after which it is placed in airtight bottles and supplied to the consumer. These bottles are returnable, and are carefully steamed and cleaned, often with electrically driven brushes, before being refilled. The factories for butter-making have been of special particular service in Ireland.

Where the production of butter is the object of a combine, the regulations as to stock, housing, &c. are the same as for the milk-selling dairy. This system of butter production has the advantage of economy of labour and the manufacture of large quantities under the supervision of one skilled operator. The milk is brought to the creamery by the farmers, or in some cases a motor-van is sent round to the various farms to collect supplies. On arrival at the factory the milk is weighed and tested for butter-fat percentage, as payment is based on the amount of fat present. The payment for milk on its fat content is obviously the only reasonable method where the percentage of fat entirely controls the amount of butter produced from a given quantity of milk. Another advantage of this system of purchase is that, in selecting cows to build up a herd, the farmer must purchase and breed from cattle which are not only heavy milkers, but are known to produce milk of a high fat percentage. This will in time increase the efficiency, as milk-producers, of the dairy cattle of Great Britain. The Cream (q.v.) is removed from the milk received at the factory by centrifugal separators, and the separated milk returned to the farmers. In order to avoid the introduction of deleterious bacteria, the whole of the cream received is pasteurised. As the process of pasteurisation kills the living germs, which would produce ripening, as well as those of a dangerous nature, it is necessary to add a 'starter' (see BUTTER). This is done by adding a pure culture of the lactic acid bacteria, which produces an even condition of ripeness throughout the whole quantity of cream received.

Cheese factories, though not numerous in England, are conducted under the same initial regulations as milk-selling or butter factories, the type of cheese usually produced being the Cheddar (see CHEESE). Factories producing condensed milk are not usually on the co-operative system, but simply purchase their supplies by contract. It is rare for a factory to be built to deal with the milk of less than 300 cows. The average cost of building and erecting a factory for about 500 cows was approximately £2 per cow, but the cost per cow increases as the number decreases,

and for this reason the above-mentioned 300 may be taken as a minimum for economic working.

See CATTLE, MILK, CREAM, BUTTER, CHEESE, AGRICULTURE.

**Daisy** (*Bellis*), a genus of tubulifloral composites (family Asteroidae) characterised by its conical receptacle and absence of pappus. The twelve or fifteen species are palaearctic, save *B. integrifolia*. The familiar species in Britain and Europe is *B. perennis*. The yellow button-like disc is composed of a myriad of small perfect flowers, with yellow five-cleft tubular corolla, and ring of fused stamens surrounding the pistil. The marginal or ray flowers have no stamens, and are female; their corolla is white, and largely expanded outwards. Of calyx there is hardly a trace; but the head is surrounded by a close-fitting double ring of small leaves, the involucre, which encloses the whole when in bud. Double varieties, crimson, pink, white, or striped, are common in gardens, and frequently produce smaller heads in the axils of the involucre bracts of the main capitulum (*Hen-and-chickens*). It has been sparingly introduced into America, where there is a native species (*B. integrifolia*) in Kentucky, Tennessee, Arkansas, and the south-western states. The plant commonly called daisy in the United States is the Ox-eye Daisy, really a *Chrysanthemum* (q.v.). Christmas and Michaelmas Daisies are species of aster. In pastures daisies are unhappily noxious weeds, eaten by no kind of farm-stock, and exhausting the soil; and their spreading clusters cover up and supersede the grass around each centre.

**Dāk**, or DAWK, the mail-post of India; also travelling by Palanquin (q.v.). See BUNGALOW.

**Dakar**, a port of Senegal, and since 1903 capital of French West Africa, is on the southern side of the peninsula of Cape Verde, on the bay of Goree and sheltered by the island of Goree, on which till after the middle of the 19th century the main French settlement was situated. The port has safe anchorage for large vessels, and since 1904 great harbour works have been carried out, so that there are now commercial docks, a naval dock, an arsenal, with admirable quay and railway facilities. The port, the terminus of railways to St Louis and to the interior, commands the trade of the Upper Senegal and the Middle Niger, and, owing to its position, is a great port of call. Pop. with suburbs, 32,000. See SENEGAL, SENEGAMBIA.

**Dakota**. See NORTH DAKOTA, SOUTH DAKOTA; and for the Dakota Indians, see SIOUX.

**Dalai'-Lama**. See LAMAISM.

**Dalbeattie**, a town of Kirkcudbrightshire, near Urr Water, 15 miles SW. of Dumfries. Founded in 1780, it owed its importance to the neighbouring Craignair quarries (now almost exhausted), and to its polishing-works, which furnished granite for the Liverpool and Odessa Docks, the Thames Embankment, &c. Pop. 3000.

**Dalberg**, an ancient and noble German family which long held by hereditary right the office of chamberlain to the archbishopric of Worms. So great was its renown that at every coronation of a German emperor the herald exclaimed, 'Is there no Dalberg here?' whereupon the representative of the family knelt, and received from the new emperor the dignity of 'first knight of the empire.' One of the most eminent members of this family was Karl Theodor (1744-1817), the last prince-bishop of Mainz, who, trained for the church, held numerous high offices, and ultimately became elector of Mainz, chancellor of the empire, and primate of Germany. He was a friend of Wieland, Herder, Goethe, and Schiller, and wrote works on history, philosophy, and aesthetics.

**Dalbergia**, a tropical genus of papilionaceous trees and climbers. Some of them are valuable timber-trees, particularly the *Sissoo* of Bengal (*D. Sissoo*) and *D. melanoxylon* of Senegal (Senegal Ebony, q.v.). *D. monetaria*, of Surinam, yields a resin very similar to Dragon's Blood.

**D'Albert**, EUGEN, musician, born in Glasgow, 10th April 1864, studied under Pauer, Richter, and Liszt, and made his début in Berlin in 1883. Kapellmeister for a short time at Weimar, he lived mostly in Berlin and Lucerne, famous first as a pianist, later as a composer of operas (*Tiefhand* the best known), piano concertos, a symphony in F, and many songs.

**Dale**, DAVID, was born 6th January 1739 at Stewarton in Ayrshire. Early apprenticed to a Paisley weaver, he afterwards travelled some time round the country, buying up homespun linen yarn, next became clerk to a silk-mercator, then an importer of French and Dutch yarns. On Arkwright's visiting Scotland it was agreed that he and Dale should engage in cotton-spinning together at New Lanark near the Falls of Clyde. There Dale built mills, and became prosperous. In 1799 he sold these mills to Robert Owen (who became his son-in-law) and his partners. Dale spent his last years in active works of benevolence in Glasgow, and in preaching to a church of his own which called itself the 'Old Independents.' He died at Glasgow, 17th March 1806.

**Dalecarlia**, or DALARNÉ (signifying 'valley-country'), an old province of central Sweden, now forming the lan or county of Kopparberg. The Dalecarlians are celebrated for the part they took under Gustavus Vasa in freeing their country from the yoke of Christian II. of Denmark.

**D'Alembert**, JEAN LE ROND, mathematician and encyclopædist, was born in Paris, November 16, 1717, and was found the day after his birth near the church of St Jean-le-Rond, from which he derived his name—the surname he himself added long after. He was the illegitimate son of Madame de Tencin and the Chevalier Destouches, and was brought up by the wife of a poor glazier; but his father, without publicly acknowledging the paternity, secured to him an allowance of 1200 francs a year. At twelve the boy entered the Collège Mazarin, where he soon showed his lifelong passion for mathematical studies. On leaving college, he returned to the humble home of his kind foster-mother, where he continued to live and pursue his favourite studies for thirty years, broken only by two ineffectual attempts to earn a living by law and medicine. 'You will never,' said his foster-mother, 'be anything but a philosopher; and what is a philosopher, but a fool who torments himself during his life that people may talk about him when he is dead?' His first distinction was admission at twenty-three to the Academy of Sciences. Two years later appeared his *Traité de Dynamique*, which reduces all the laws of motion to the consideration of Equilibrium, thereby making an epoch in mechanical philosophy. Later works were *Réflexions sur la Cause générale des Vents*, which gained the prize of the Academy of Berlin, 1746, and which contains the first conception and use of the Calculus of Partial Differences; *Traité de l'Équilibre et du Mouvement des Fluides* (1744); *Recherches sur la Précession des Équinoxes et sur la Mutation de l'Axe de la Terre* (1749); and *Recherches sur Différents Points Importants du Système du Monde* (1754). His *Opuscules Mathématiques* (8 vols. 1761-80) contain an immense number of memoirs, some on new subjects, some containing developments of his previous works.

But D'Alembert did not confine himself to

physical science. For the great *Encyclopédie* planned by Diderot he wrote the famous *Discours Préliminaire*, a noble tribute to literature and philosophy, a model of lucid and eloquent exposition, although its classification of the sciences is open to question. Besides numerous articles in the *Encyclopédie* (the mathematical portion of which he edited), he published books on philosophy, literary criticism, the theory of music, and a treatise, *Sur la Destruction des Jésuites* (1765), which involved him in controversy. He became secretary to the Academy in 1772, and thereafter he wrote the lives of all the members deceased between 1700 and that year—one of the most pleasing of his works. His literary works have been published in a collected form, new edition, by Bossange (Paris, 5 vols. 1821). This edition contains his correspondence with Voltaire and the king of Prussia. His scientific works have never been collected.

So genuine was D'Alembert's love of independence that wealth and rank had no fascination for him. Frederick II. of Prussia offered him the presidency of the Academy of Berlin in 1752, but he declined to leave France, and only accepted a subsequent offer of a pension of 1200 francs. The king of France granted him a similar sum. In 1762 Catharine II. of Russia invited him, through her ambassador, to undertake the education of her son, with a salary of 100,000 francs; and when he declined, she wrote him an autograph letter, urging that to refuse to contribute to the education of a whole nation was inconsistent with his own principles; and inviting him, if he could not reconcile himself to the breaking-off of his pursuits and friendships, to bring all his friends with him, and she would provide both for them and for him everything they could desire. But he remained steadfast. D'Alembert never married. He was tenderly attached for many years to Mademoiselle Lespinasse (q.v.), with whom he lived in the same house in Platonic affection for nearly a dozen years, but who was scarce worthy of his devotion. Her death in 1776 was a crushing blow to the philosopher. He died October 29, 1783. See his *Œuvres et Correspondances inédites*, edited by Charles Henry (1887); the Life by J. Bertrand (Par. 1889); and Ducros, *Les Encyclopédistes* (1900).

**Dalgarno**, GEORGE, an almost forgotten but very able author, was born at Aberdeen about 1626, studied at Marischal College, and afterwards kept a school in Oxford for thirty years, where he died August 28, 1687. He deserves to be remembered for two remarkable works—the *Ars Signorum*, *vulgo Character Universalis et Lingua Philosophica* (1661), and *Didascalocophus, or the Deaf and Dumb Man's Tutor* (1680). The former is a very ingenious attempt to represent and classify ideas by specific arbitrary characters irrespective of words. It contains the germs of the 'Universal Language' (q.v.) of Bishop Wilkins (q.v.). See DEAF AND DUMB.

**Dalgety**, formerly called BUCKLEY'S CROSSING, was in 1904 proposed as Federal capital of the Commonwealth of Australia. In the south-east corner of New South Wales, the township is 296 miles SW. of Sydney. It was set aside in favour of Canberra.

**Dalhousie**, JAMES ANDREW BROWN-RAMSAY, MARQUIS OF, Governor-general of India, and 'greatest of Indian proconsuls,' was the third son of the ninth Earl of Dalhousie, and was born April 22, 1812, at Dalhousie Castle, Midlothian. He was educated at Harrow, and graduated at Christ Church, Oxford. In 1832, by the death of his only remaining brother, he succeeded to the courtesy title of Lord Ramsay. In 1835 he stood unsuccessfully for Edinburgh in the Conservative interest; in 1837

was elected for Haddingtonshire. On the death of his father in 1838 he entered the House of Peers as Earl of Dalhousie. In 1843 Sir Robert Peel appointed him Vice-president of the Board of Trade, and in 1845 he succeeded Mr Gladstone as President of the Board. The 'railway mania' threw an immense amount of labour and responsibility upon his department; but the energy, industry, and administrative ability he displayed in his office, no less than his readiness and fluency in parliament, marked him out for the highest offices in the state. When Peel resigned office in 1846, Lord John Russell paid the Earl of Dalhousie the rare compliment of asking him to remain at the Board of Trade, in order to carry out the regulations he had framed for the railway system. In 1847 he was appointed Governor-general of India, as successor to Lord Hardinge, and arrived in Calcutta, January 12, 1848—the youngest governor-general ever sent to that country. His Indian administration was not less splendid and successful in regard to the acquisition of territory than in the means he adopted for developing the resources of the country, and improving the administration of the East Indian government. Pegu and the Punjab were conquered; Nagpur, Oudh, Sattara, Jhansi, and Bejar were annexed—together, four great kingdoms, besides a number of minor principalities, were added to the dominions of the Queen. Railways on a colossal scale were planned, and partly commenced; 4000 miles of electric telegraph were spread over India; 2000 miles of road between Calcutta and Peshawar were bridged and metalled; the Ganges Canal, the largest of the kind in the country, was opened; important works of irrigation all over India were planned and executed; and the department of public works was reorganised. Among other incidents of his beneficent administration may be mentioned his energetic action against suttee, thuggee, female infanticide, and the slave-trade; the organisation of the Legislative Council; the improved training of the civil service, which was opened to all natural-born subjects of the British crown, black or white; the successful development of trade, agriculture, forestry, mining; and a great reform in the postal service of India. In a minute which he drew up on resigning office, he reviewed with pardonable pride the events of his eight years' governor-generalship. His constitution had never been strong, and it gave way under the incessant labour and responsibility imposed upon him by his noble ambition. Meanwhile, honours had been showered upon him by his Queen and country with no sparing hand: in 1848 he was made a Knight of the Thistle; in 1849 he received the marquissate, the thanks of both Houses of Parliament and of the East India Company for the 'zeal and ability' displayed in administering the resources of British India in the contest with the Sikhs; in 1852, on the death of Wellington, he was nominated by the then prime-minister, the Earl of Derby, to the office of Constable of Her Majesty's Castle of Dover and Lord Warden of the Cinque Ports. Dalhousie sailed from Calcutta in March 1856. On his arrival in England he was unable to take his seat in the House of Lords; and the remainder of his days was spent in much physical suffering and prostration of strength. On 19th December 1860 he died at Dalhousie Castle in his 48th year, leaving behind him a name that ranks among the highest in the roll of Indian viceroys for statesmanship, administrative vigour, and the faculty of inspiring confidence among the millions subjected to his sway. As he died without male issue, his title of marquis became extinct, the earldom of Dalhousie and other Scottish honours reverting to his cousin, Baron Panmure. His policy of annexation has been blamed for the

mutiny which broke out ere his death; but though, in Justin M'Carthy's words, 'he was a man of commanding energy and indomitable courage, with the intellect of a ruler of men and the spirit of a conqueror,' he was also of a most sensitive conscience, and entered on the Sikh and Burmese wars and embarked on a policy of annexation against his will.

See the articles **INDIA**, **ODDE**, **PEGU**, **PUNJAB**, **SIKHS**; the Duke of Argyll's *India under Dalhousie and Canning* (1865); Trotter's *Dalhousie* (1889); the Life by Lee-Warner (1904); and his *Private Letters* (ed. Baird, 1910).

**Dalhousie**, an Indian hill sanatorium in the Himalayas, at the altitude of 7700 feet, 93 miles N.E. from Amritsar. It was first occupied in 1860. Pop. 1600.

**Dalkeith**, a town of Midlothian, 6 miles S.E. of Edinburgh, on a tongue of land between the North and South Esks. There is a large corn exchange (1855); of nearly a dozen places of worship the only old one is the parish church, collegiate once, of which Norman Macleod was for three years minister. The chief glory of the place is Dalkeith Palace, a seat of the Duke of Buccleuch (see **SCOTT**). Standing near the end of the High Street, in a beautiful park of 1035 acres, it is a Grecian edifice, built in 1700 by Sir John Vanbrugh for Monmouth's widowed duchess. The castle, its predecessor, was the seat first of the Grahams, and then of the Douglasses from the 14th century till 1642, when the ninth Earl of Morton sold it to the second Earl of Buccleuch. Dalkeith thus has memories of the Regent Morton (the 'Lion's Den' the castle was called in his day), of General Monk (1654-59), and of visits from James IV., James VI., Charles I., Prince Charles Edward, George IV., and Queen Victoria. Professor Tait was a native; it is the scene, too, of Moir's *Mansie Wauch*. Pop. (1841) 4831; (1881) 6931; (1921) 7238.

**Dallas**, capital of Dallas county, Texas, on Trinity River, 265 miles NNW. of Houston by rail. It has schools and colleges, flour-mills and meat packing concerns, and manufactures of agricultural and cotton-gin machinery, cotton-seed oil-cake, petroleum, and much else. Pop. (1880) 10,358; (1900) 42,638; (1910) 92,104; (1920) 158,976.

**Dallas**, **GEORGE MIFFLIN**, an American diplomatist and statesman, was born in Philadelphia, July 10, 1792. His father, A. J. Dallas (1759-1817), was a distinguished lawyer of West Indian birth and Scottish descent, who filled with credit the positions of secretary of the treasury and acting-secretary of war under President Madison. The younger Dallas graduated at Princeton College in 1810. In 1813 he was admitted to the bar, and soon after entered the diplomatic service. In 1831 he was sent to the United States senate by the Pennsylvania legislature. He was United States minister to Russia from 1837 to 1839, and in 1844 was elected vice-president of the United States. In 1846 his casting-vote as president of the senate repealed the protective tariff of 1842, though he had previously been considered a Protectionist. His course on this question aroused much indignation in Pennsylvania. He was sent to Great Britain as United States minister at St James's from 1856 to 1861. He died at Philadelphia, December 31, 1864. His principal published writings were posthumous; they include a very readable and entertaining series of *Letters from London* (1869), and a *Life of A. J. Dallas* (1871). His life was marked by assiduous devotion to official duties, which left him little leisure to look after his own private interests, and he lived and died a poor man.

**Dalles**. See **COLUMBIA RIVER**.

**Dalling**, **LORD**. See **BULWER**.

**Dalmatia**, a narrow strip of Yugo-Slav territory extending along the Adriatic Sea, and bounded on the N. by Croatia, on the E. by Bosnia, Herzegovina, and Montenegro; area, 5000 sq. m.; pop. (1921) 621,429. The coast of Dalmatia and numerous adjacent islands is everywhere steep and rocky, and the chief towns, all of which are on the coast, are Sebenico, Lissa, Spalato, Brazza, Ragusa, and Cattaro. The country is mountainous, chiefly dry moorland, with numerous small lakes and rivers, most of which dry up in summer. The highest mountain is Orjen, near Cattaro, 6235 feet. The climate is uncertain; mean temperature about 60°; rainfall about 28 in. The Bora (q.v.) wind is much dreaded. About one-ninth of the land is arable, and produces wheat, barley, oats, maize, rye, and potatoes. Wine and olives are also produced. Nearly half of the land is in pasture, and wood occupies about a third. The islands are not very fertile, but supply good timber for shipbuilding. Cattle-rearing, seafaring, and the fisheries are the chief industries. The exports consist principally of wine, oil, brandy, hides, wool, wax, honey, and fruits. The population includes a considerable (but disputed) number of Italians, with some Albanians, Germans, and Jews, and the remainder consists of Southern Slavonians—chiefly Dalmatians and Morlaks. The Dalmatians are a fine race of men, bold and brave as seamen and soldiers, and formerly were the main support of the military power of Venice.

In ancient times Dalmatia was a considerable kingdom, first subjugated, after many attempts, by the Romans in the time of Augustus. On the fall of the Western Empire, Dalmatia, which had formed the southern part of Illyricum, was captured by the Goths, from whom it was taken by the Avari (490), who in their turn yielded it to the Slavonians about 620. The state founded by these continued until the beginning of the 11th century, when King Ladislaus of Hungary incorporated part with Croatia, while the rest (as a duchy) placed itself under Venetian protection. The Turks afterwards made themselves masters of a small portion; and by the peace of Campo-Formio (1797) the Venetian part, with Venice itself, became subject to Austria. When Austria, in 1805, had ceded this part to Napoleon, it was annexed to the kingdom of Italy; afterwards (1810) to Illyria. From 1814 Dalmatia formed part of Austria, the commune of Spizza being added by the Congress of Berlin in 1878. Italy looked upon Dalmatia as part of Italia Irredenta. The Slavs of Dalmatia, on the other hand, shared in the Illyrian nationalist movements of the 19th and 20th centuries, aspiring either to incorporation in a Greater Serbia or Yugo-Slav state, or to equal status with Austria and Hungary in a trial monarchy. The Great War and the break-up of Austria-Hungary brought the Yugo-Slavs their opportunity; Dalmatian independence was declared in October 1918, and representatives sent to a Yugo-Slav National Council.

**Dalmatian Dog**, or **CARRIAGE-DOG**, a variety of dog closely resembling in size and shape the modern pointer. It is often kept in stables, becomes attached to the horses, and may be seen running after carriages. Its colour should be white with black spots not more than an inch in diameter regularly distributed over its body, including its ears and tail. Its origin is uncertain; the name Dalmatian is probably altogether misleading; and it is supposed that it may have been brought from India, where a very similar kind of dog exists.

**Dalmatic** (*Dalmatica*), the deacon's robe in the Roman Catholic Church. The most ancient form of the dalmatic is exhibited in the annexed

woodcut, after an early Christian painting on a wall in the catacombs at Rome. It was originally

of linen, but it is now generally made of the same heavy silk as the Chasuble (q.v.). In Italy it is still a tunic with wide sleeves, but open up the sides; in most countries it is rather a cloak open at the sides, and instead of sleeves has square-cut lapports falling over the top of the arm. It is worn by deacons at High Mass, processions, and benedictions. It was originally the Dalmatian under-garment of

civilians, and was made of native white wool.

**Dalmellington**, an Ayrshire village, near the Doon, 15½ miles SE. of Ayr, with large collieries and ironworks.

**Dalny**. See DAIREN.

**Dalri'ada** ('the home of the descendants of Riada'), the ancient name of a territory in Ireland, comprehending what is now called 'the Route,' or the northern half of County Antrim. Its inhabitants were Gaelic Scots living in the midst of a Pictish population, and a number of them crossed over to Argyll in 498 and founded there another Dalriada, the nucleus of the kingdom of the Scots of Alban, who ultimately gave a dynasty to North Britain. See SCOTLAND.

**Dalry**, a town of Ayrshire, on the Garnock, 23 miles SW. of Glasgow. Pop. 4000. It increased rapidly in size after the establishment of neighbouring ironworks in 1845.—For the skirmish at Dalry, near Tyndrum, see BRUCE.

**Dalrymple**, ALEXANDER, hydrographer, was a younger brother of Sir David Dalrymple, Lord Hailes, and was thus a member of an old and illustrious Scottish family (for its chief members, see STAIR and HAILES); he was born at New Hailes, near Edinburgh, 24th July 1737. At fifteen he sailed for Madras as writer in the East India Company's service, and after a few years' dreary work began to attract the notice of his superiors by his industry and intelligence. In 1759 he made a voyage of observation among the eastern islands, and after returning to Madras in 1762, was sent to open up the trade with Sulu, reaching Canton late in 1764. In 1775 he went to Madras as a member of council, but was recalled two years after on an unfounded charge of misconduct. He became hydrographer to the East India Company in 1779, and to the Admiralty in 1795, and died, three weeks after his summary dismissal from the latter office, 19th June 1808.

**Dalrymple**, SIR JAMES, was the second son of Sir James Dalrymple, baronet, afterwards first Viscount Stair. He was called to the Scottish bar in 1675, and ultimately became one of the chief clerks of the Court of Session, and a Nova Scotia baronet in 1698. He was a sound antiquary, and his work entitled *Collections concerning the Scottish History preceding 1153* (Edin. 1705) is still of value.

**Dalton**, JOHN, chemist and physicist, born about 6th September 1766, at Eaglesfield, near Cockermouth, in Cumberland, was the son of a Quaker weaver. He received his early education at a

Quaker school in his native place, and, after 1781, in a boarding-school kept by a relative in Kendal, of which three years later he and a brother became the proprietors. Here his love of mathematical and physical studies was first developed. He wrote several mathematical essays, and in 1787 commenced a journal of meteorological observations, which he continued throughout his whole life, recording in all 200,000 observations. He collected butterflies, and gathered a great hortus siccus and herbarium. In 1793 he was appointed teacher of mathematics and the physical sciences in New College, Manchester: after the removal of the college to York in 1799, he supported himself in Manchester by private tuition. In 1803 he lectured at the Royal Institution. His *Meteorological Observations* (1793), dealing largely with auroras, contained the germs of many of his future discoveries. In 1794 he first described the phenomena of colour-blindness, observed by him in his own case and that of his brother, and often called Daltonism. In 1808–10 he published his *New System of Chemical Philosophy*, to which he added the first part of a second volume in 1827. In 1817 he was appointed president of the Manchester Philosophical Society. He was also a member of the Royal Society, and an associate of the Paris Academy, and of several other foreign societies. In 1833 he received a pension of £250, afterwards raised to £300. In the same year Dalton's friends and fellow-townsmen collected £2000, to raise a statue to his honour, which was executed by Chantrey, and placed at the entrance of the Royal Institution in Manchester. Oxford gave him its D.C.L., and Edinburgh, LL.D. He was twice a vice-president of the British Association. In 1837 he had a shock of paralysis, and he died, universally respected, at Manchester, July 27, 1844. His chief physical researches were on the constitution of mixed gases, on the force of steam, on the elasticity of vapours, and on the expansion of gases by heat. In chemistry, he distinguished himself by his development of the atomic theory, as also by his researches on the absorption of gases by water, on carbonic acid, carburetted hydrogen, &c. Dalton was unquestionably one of the greatest chemists that any country has produced. Profound, patient, and intuitive, he had precisely the faculties requisite for a great scientific discoverer. His atomic theory elevated chemistry into a science. In his habits, Dalton was simple; in manners, grave and reserved, but kindly, and distinguished by his truthfulness and integrity of character. He 'never found time' to marry. See LIVES by Angus Smith (1836); Henry (1854); Lonsdale (1874); and Sir H. Roscoe (1895); and the article ATOMIC THEORY.

**Dalton-in-Furness**, a town of Lancashire, 16 miles WNW. of Lancaster, communicating with the sea by a canal (3½ miles). It has extensive malting and ironworks; and the ruins of Furness (q.v.) Abbey are in the vicinity. Romney was a native. Pop. (1861) 2812; (1921) 12,303.

**Daltonism**. See COLOUR-BLINDNESS.

**Dalyell**, or DALZELL, THOMAS, a Scottish general famed for his zeal in the repression of the Covenanters, was born about 1599, the son of Thomas Dalyell of Binns, Linlithgowshire. He served in the Rochelle expedition (1628) and in Ireland, was taken prisoner at Worcester (1651), but escaped. In 1655 he entered the service of Russia, and distinguished himself in the wars against the Tatars and Turks. At the request of Charles II. he was permitted to return home, and in 1666 was appointed commander-in-chief in Scotland with the view of repressing the Covenanters. On 28th November he defeated them at Rullion Green, in the Pentlands, and, in Burnet's

words, 'acting the Muscovite too grossly,' made his name a byword of terror. A very devoted royalist, he is said never to have shaved his beard after the execution of Charles I. He died 23d August 1685.

**Dam.** See WATER, COFFERDAM.

**Damages**, in Law, are the pecuniary reparation due for loss or injury sustained by one person through the fraud or negligence of another. Where a sum ascertained in amount is due, the action is one not properly for damages, but of debt. But where the sum is not ascertained, as where an injury has been done to a man's character or property, the action can in general only be for damages the amount of which the injured party estimates, and which is determined by the judgment of the court or verdict of a jury. When parties to a contract agree that if the contract be broken, a specified sum of money shall be paid, this sum is spoken of as liquidated damages, a sum agreed upon to save the trouble of ascertaining the actual damage done. Nominal damages are those given to a plaintiff who establishes his right, but has not shown that he has suffered actual loss. Exemplary or vindictive damages are given not only to compensate the injured party, but to punish the offender, as in actions for damages by fraud, seduction, and the like. Damages *ultra* are additional damages claimed by a plaintiff over and above those paid into court by a defendant. Every person is liable in damages for injuries caused by culpable neglect or ignorance. Professional persons are liable to make reparation of loss occasioned through their want of ordinary skill in their calling. Employers are liable for injuries to person or property caused by the fault of themselves or their servants. The principal rules according to which damages are awarded are, that they are given only for actual pecuniary loss (in Scotland, however, also for wounded feelings); that the injury suffered must be the immediate consequence of the faulty act or omission; and that all the parties concerned in committing a wrong are liable each for the full amount of damages to the injured party.

The growth of corporations, such as limited liability companies, has necessitated the settlement of many difficult points; but now a corporation is liable in damages for fraud, negligence, or even slander on the part of one of its officials or employees, if the act was done within the scope of their authority or employment, in the same way as an individual employer would be. A corporation may even be prosecuted for an official's crime if the offence is one where guilty intention is not an essential, and where the penalty is a money fine. See COSTS.

**Daman'**, an outlying portion of the Punjab and of the NW. Frontier Province, extending along the Indus, and as far back as the Suliman Mountains.

**Daman'**, a Portuguese settlement and port in the province of Gujarat, on the Gulf of Cambay, 100 miles N. of Bombay. The settlement consists of Daman proper (22 sq. m.), and the *pargana* of Nagar Havili (60 sq. m.), to the east. Pop. of the former, 56,084; of the latter, 12,636, nearly all Hindus. The climate is generally healthy, the soil moist and fertile. The magnificent teak forests of Nagar Havili provide excellent timber for shipbuilding, for which Daman has some celebrity. The port, guarded by two forts, stands at the mouth of the Daman-Ganga, a deep, navigable stream, with a bar at its mouth, while outside is an excellent roadstead. Although the Portuguese have held Nagar Havili since 1780 only, Daman has been occupied by them since 1558. It formerly was noted for its weaving and dyeing, and exported its own fabrics to the

coast of Africa, besides opium to China; but now the chief industries are fishing and weaving.

**Daman.** See HYRAX.

**Damanhur**, a town of Lower Egypt, capital of the province of Beherah, 10 miles from Alexandria, is an important station on the Cairo to Alexandria railway. Pop. 50,000.

**Daman-i-Koh** ('skirts of the hills'), a tract of hilly country in Bihar, reserved for the Santals and other equally primitive races. Area, 1351 sq. m.; pop 360,000.

**Dam'araland**, a territory in the west of South Africa, between Namaqualand and Ovampoland proper, extending from the Atlantic to about 19° 45' E. long. Behind the waterless coast region (100 miles) rises a mountain district, with peaks over 8500 feet above the sea; and farther inland stretch wide prairies. The mountains are rich in minerals, especially copper; vegetation is confined to their valleys, and to the prairie region, which in the north enjoys a fine rainfall. Damaras is a Hottentot name for the Ova-Hereio, a Bantu (q.v.) stem, who may number 70,000, and own large flocks and herds. Distinct from the Cattle Damaras are the lower Hill Damaras, who are largely Hottentot in blood and speak Hottentot. Walvisch Bay (q.v.), the best port, belongs to the Cape Province; Swakopmund was improved by the Germans, who from 1884-90 owned the territory. With the rest of German South-west Africa, Damaraaland was conquered by the Union, to which the mandate for its administration was given in 1919. Windhoek is capital of the whole.

**Damascening**, or DAMASKENING, is a name which is given (1) to the watered or striated structure seen in certain sword-blades and other weapons, and (2) to the ornamental incrustation with gold and silver of steel and iron surfaces. The term in both its applications originates from the city of Damascus, whence the crusaders brought into Europe swords and other weapons of remarkable strength, elasticity, and keenness of edge, the surfaces of which were beautifully striated with waved dark and light lines. The hilts of such weapons, and the whole surface of defensive armour from the same source were in many cases elaborately ornamented with incrustated gold, and hence one term came to be applied to the peculiar structure of the metal, and to its ornamental treatment. It is probable that even in the crusaders' times the making of the so-called Damascus blades and the art of damascening were Persian, and to this day they remain characteristic of that country, the practice having spread thence eastward into India, while the Persians still supply the Turks on the west with their best and most highly ornamented weapons. The production of a watered or damascened surface is illustrated by the manufacture of 'Damascus twist' barrels for sporting-guns. The metal for the barrels is prepared from rods of iron and steel, piled alternately and forged and welded together into a single solid rod of small section. Three of these composite rods are used in forming a barrel. They are separately twisted in contrary directions till each has the appearance of a fine threaded screw, then they are welded together into a solid ribbon, which in its turn is spirally wound and welded by the edges till the requisite length and bore of barrel are formed. The result of the intertwisting of fine laminæ of steel and iron is a beautifully damascened surface which shows itself when the barrel has been treated with acid. The incrustation of arms, armour, and other objects of steel and iron with gold, and more rarely with silver, is very extensively practised in the United Provinces of India, as well as in Persia. In India it is known as Kufi work or Kufigari. The

design to be worked out is undercut in the metal, into this the gold or silver wire is laid, and the scarp edge is beaten down with a hammer, thus securing the wire in its position. Another method consists in scratching the surface, and beating into the scratched lines the gold or silver wire, after which the whole surface is burnished to remove the incisions. See GUN.

**Damascenus.** See JOANNES DAMASCENUS.

**Damascus** is the capital of the state of Damascus in Syria. It is called by the natives *Dimashk es-Sham*, or simply *es-Sham*, the name which is generally applied to all Syria. It stands  $1\frac{1}{2}$  mile from the mouth of the gorge through which the Barada, the *Chrysorrhoea* of the Greeks, forces its way into the plain; and it is connected with Beyrout on the Mediterranean by an excellent road (70 miles) and a railway. The plain of Damascus, 500 sq. m. in area, is dotted by over a hundred towns and villages. It is bounded on the north-west by the Anti-Libanus range, on the south by the Black Mountains, beyond which are the hills of Bashan, and on the east by the marshes of the plain. Damascus is situated on the western side of the great plain at an elevation of 2260 feet above the level of the sea, and immediately to the north-west of the city the Anti-Libanus rises to a height of 3840 feet. This elevated part of the mountain, called Jebel Kasyún, is crowned by the Kubbet en-Nasr ('Dome of Victory'). From the base of this dome the best view of Damascus is obtained. Its exquisite beauty, as seen from the mountain, is greatly enhanced by contrast. Towards the west there are the bare chocolate sahara and the storm-bleached, lime-streaked mountains. But the Barada, having forced its way through the mountain, spreads fan-like by seven rivers over the plain of Damascus, 'and everything lives whither the river cometh.' A beautiful green meadow, the joy of all orientals, extends almost from the mountain to the city; gardens, in which all the trees of the forest and the field blend their many shades, extend for many a mile and hold the desert at bay. From out this bower of soft green the city lifts to heaven its forest of minarets towering above pearly domes. The rivers of Damascus are the constant source of the city's perennial existence. According to tradition, Abraham on his westward march lingered by the crystal waters, and ruled the city in peace.

The seven canals by which water is drawn off from the central Barada are called rivers. The most important on the right side is Nahar Abanias. This is the river Abana, and it flowed through the fashionable west-end suburb in the palmy days of Damascus. The most important canal on the left side of the Barada is Nahar Taura—the Pharpar of 2 Kings, v. 12. Both rivers flowed through the residential parts of the city, and were largely used for bathing purposes.

The appearance of Damascus as viewed from the mountain resembles a tennis-racquet. The handle, which lies in a south-westerly direction, is the Meidan, a suburb which extends along the Mecca pilgrim-route for about a mile, and ends at the Bawabat Alla ('Gate of God'). The other part is concentrated on the rivers, and is inclosed within ancient walls and encompassed by luxuriant gardens which seem to surge around and over the pearl-coloured city like a sea. At the western side of the city within the walls stands the citadel. It is a large quadrangular structure about 300 yards long and 250 wide, with projecting towers, and surrounded by a moat. It was erected in 1219 by Melik-el-Ashraf, and has a massive appearance, but it is a good deal dilapidated. The palace stands outside the walls west of the citadel, and about 400

yards east of the citadel stands the Great Mosque, burnt in October 1893. The Mosque was erected by Walid 'Abd-el-Melik at the beginning of the 8th century on the site of the church of St John, just as that church had been erected by Arcadius about the beginning of the 5th century on the site of a pagan temple, which probably occupied the site of the ancient *Beit Rimmon*. The church was constructed from the splendid material of ancient temples, and the mosque is made up of the materials of ancient churches. The old walls and many of the columns of the church are still in position, and on a portal, older than Mohammedan or Christian times, is carved a cross, followed by the 13th verse of the 145th Psalm in Greek, from the Septuagint, with the abbreviation X $\epsilon$  added. The mosque is adorned by three minarets, one of which, called the minaret of Jesus, rises to a height of 250 feet, and on this minaret, according to Mohammedan tradition, Jesus will appear when he comes to judge the world. Near to the pulpit there is a richly gilded dome, beneath which the head of John the Baptist is said to rest, and in the court there is another dome which contains precious fragments of Kufic, Syriac, and other manuscripts. Damascus contains 70 other mosques, and more than 150 chapels for prayer and instruction. The churches and synagogues have no architectural pretensions, and their internal decorations are gorgeous but tawdry. The tomb of Nûr ed-Dîn is one of the ornaments of the city, and the walls of the best baths are decorated with beautiful Kishani tiles, and the floors with parian marble. The public cafés, though picturesque when lighted up, are dirty and sodden.

The religious communities occupy different quarters of Damascus. The Jewish quarter (*Harat-el-Yahoud*) lies to the south of the 'street called Straight,' which runs east and west for about a mile, with Roman gateways at either end. The course of the *Via Recta* can be traced by the columns *in situ*. The Christian quarter (*Harat-en-Nasara*) lies north of the street called Straight in the eastern part of the city, and the remainder of the city is occupied by Mohammedans. It is spoken of as *Harat-el-Islam*. The Christians are superior in physique, in education, in enterprise, in skill, in industry to their Mohammedan neighbours.

The different industries are also carried on in separate quarters. There is the silversmiths' bazaar, where rough but very effective personal ornaments are made; the saddlers' bazaar, where scarlet saddles and horse-trappings are gaily decorated with gold and silver thread; the shoemakers' bazaar, where red and yellow slippers of gondola-form and gorgeous top-boots are made; the Greek bazaar, where imitation 'Damascus blades' and 'antiques' newly made are offered to the unwary. The book bazaar (the Paternoster Row of the East), the cloth bazaar, the seed bazaar, the silk bazaar, and all the other trades and commodities, have their distinct locations. The narrow and badly paved streets of Damascus are dusty in summer and muddy in winter. On either side are the rows of arched niches which are the shops of the place. Each shopkeeper sits cross-legged in his *dukkan*, with his spices or Manchester goods piled up around him, awaiting customers, whom he serves with great stateliness of manner. Behind the mud walls and mean entrances there are splendid houses in Damascus. On entering, one is dazzled by the barbaric grandeur—white marble pavements, tessellated with coloured stone; snowy fountains where the constant music of falling water mingles with the cooing of doves from their nests in the lemon-trees or trellised vines; walls frescoed and decorated with mosaics and Persian tiles, and slabs inlaid with coloured pastes and

precious stones; arabesque ceilings set with Venetian mirrors, and adorned with blue and purple and gold—all that oriental art can do has been done to attract and charm the eye.

Great and steady progress is being made in Damascus in education, especially by the Christians; but the Jews and Mohammedans are also awaking to the necessity of a higher standard of civilisation.

One of the sights of Damascus is the Hajj (q.v.). When it is starting for Mecca the whole city turns out to see the procession. For miles around there is a surging sea of human beings, dressed in the brightest and most striking colours. Circassians and Afghans, Kurds and Kalmuks, Turkomans and Tekkes, Bedawin from the desert, and shepherds from the steppes, and all the heterogeneous tribes and peoples of the East, are represented in that brilliant procession. Damascus is also one of the meeting-places between the East and West. Enormous caravans of camels pass to and fro between Bagdad and Damascus, exchanging the dates and tobacco and spices and carpets of the East for the produce of the looms and workshops of Europe. The chief exports are grain, flour, native cotton and silk manufactures, wool, apricot paste and stones, raisins, and liquorice-root; the imports include textiles, indigo, tobacco, coffee, sugar, and leather. In 1889 tramways were introduced into the city; and a railway to its port, Beyrout, was opened in 1895, and one to Medina in 1908. Pop. about 250,000, of whom 40,000 are Christians of various sects; 10,000 are Jews. In the great war of 1914-19 Damascus fell to General Allenby and the Allies, 30th September 1918. An Arab state of Syria was set up, and Feisal, son of the king of the Hejaz, was chosen as king. The French, however, claiming a mandate, occupied Damascus (August 1920), deposed Feisal, and heavily repressed the discontented Arabs. The sanjaks of Damascus and Hama were made a state of the Syrian federation (1922), and Damascus was united with Aleppo in 1925. See SYRIA.

**Damask** is a figured textile in which the pattern is due to the method of weaving. The name indicates that the knowledge of the fabric reached the Western nations through Damascus, which in early medieval times was famous for its figured silks, as well as for other industries imported from the East. But there is no doubt that damask-weaving originated in China at a very remote period. The manufacture of damask was introduced to the commercial towns of Italy in the 13th century; and in the 15th century, under Louis XI., it was planted in Lyons and Tours in France by workmen brought from Italy. Originally damask was a rich and costly silken fabric; but in modern times it is also made from linen, cotton, wool, and other fibres, plain or dyed. When the term is unqualified it is now generally understood to apply to figured linen, chiefly used for table-linen, towels, and napkins. The structure of damask, like diaper, is merely a variety of twilling. It is by the order in which the warp threads are raised and depressed for the interweaving with the weft that the pattern is produced; the weft, as a rule, intersecting the warp from every fourth up to every eighth thread. This is accomplished by a Jacquard apparatus attached to the loom. The pattern is first painted on a specially prepared paper, and then 'read off' and perforated on cards by a cutting machine made for the purpose, each card being made to control the arrangement for one shot or weft thread. These cards, which may be from 200 to 2000 in number, are laced into an endless chain, and made to revolve on a cylinder forming part of the apparatus. The holes in the cards correspond to a certain number of cross 'needles,' into which are looped upright wires

terminating in hooks for lifting the warp threads. The mechanism for raising such of these wires (and with them the warp threads) as are required for each throw of the shuttle, is explained in the article WEAVING. It requires four Jacquard-machines to complete some patterns of damask, and a greater number if the design is exceptionally elaborate.

Table-linen damask is perhaps the kind most largely made, the finer qualities of which are distinguished as eight-leaf or double damask. An inferior table damask is woven of a combination of linen and cotton. In Great Britain, the principal seats of this manufacture are Dunfermline, Kirkcaldy, and Perth in Scotland, Belfast and Lisburn in Ireland, and Barnsley in Yorkshire. At some of the linen-damask mills in England and Scotland coloured union damask, of wool and linen, is also made on a large scale. Cotton damasks, both dyed and undyed, are woven extensively at Manchester and its neighbourhood, as well as at Glasgow and Paisley. The mills where all-wool mohair and alpaca damasks, as well as unions of these with silk, are chiefly manufactured are situated at or near Halifax and Bradford. Silk damasks are principally made in the neighbourhood of London. In the second half of the 19th century, largely through the labours of Dr Bock of Aix-la-Chapelle, one or two very interesting collections of European damasks and other figured stuffs, ranging in date from the 13th to the 15th century, were made. A valuable illustrated catalogue of the collection in the Victoria and Albert Museum (*Catalogue of Textile Fabrics, South Kensington Museum*), by Dr Daniel Rock, was published in 1870. The original pieces, even though many of them are much faded, give a vivid idea of the beauty of the products of the looms of Sicily, of Florence, Venice, Lucca, and Genoa, and of some Spanish towns, during the middle ages. The materials of which they are made are silk alone, silk and gold, silk and linen, and silk and cotton. The designs of these damasks are so appropriate and effective that even the chromo-lithographs of them are of great value not only to the textile designer, but to students of decorative art generally.

**Damaskening.** See DAMASCENING.

**Damasus**, the name of two popes of Rome.—**DAMASUS I.** was born in 306, probably at Rome, became archdeacon of the Roman Church in 355, and pope in 366. The party of Ursinus, the rival of Damasus, were overpowered after a sanguinary struggle of three days in the streets of Rome, and afterwards in the Basilica Liberiana (S. Maria Maggiore), from which 137 corpses were carried out in one day, the 25th October 366. The Emperor Valentinian I. decided in favour of Damasus, and twelve years later, the schism still continuing, an edict of Gratian (378) made him the judge in the case of all the clergy of the hostile party who still lived in Rome. He was a zealous opponent of the Arians, and condemned the Illyrian bishops Ursacius and Valens at a synod which he held at Rome in 368, and Auxentius, Bishop of Milan, at a second synod there in 370. Damasus induced his friend Jerome to undertake the revision of the *Italia* (in 383 and 384), which led him to the preparation of the Vulgate version; and he did much for the preservation and adornment of the Roman catacombs. He died in 384, and was canonised. His festival falls on the 11th December. The writings of Damasus, which are chiefly letters and epigrams, were published at Rome in 1638 (new editions, Rome, 1754, and Paris, 1840). See Langen, *Geschichte der römischen Kirche* (vol. i. Bonn, 1881), and Rade, *Damasus, Bischof von Rom* (Freiburg, 1882).—**DAMASUS II.**, previously Poppo, Bishop of Brixen, was elected pope in 1043, through the influ-

ence of the Emperor Henry III., and died twenty-three days after his accession.

**Dambula**, or DAMBUL, a vast Buddhist rock-temple in Ceylon, 40 miles N. of Kandy, containing, among a profusion of carvings, figures of Buddha of extraordinary magnitude. See CEYLON.

**Dame** (Lat. *domina*, 'a mistress'), a title of honour which long distinguished high-born ladies from the wives of citizens and of the commonalty in general, and which still is the accurate title of a knight's wife (see also BARONET). In the Order of the British Empire, Dame is the feminine equivalent of knight, Dame Grand Cross and Dame Commander (G.B.E., D.B.E.) answering to Knight Grand Cross and Knight Commander (G.B.E., K.B.E.). Ladies of those classes prefix Dame to their names. In the age of chivalry it was customary even for a queen to be so called by her chosen knight ('the dame of his heart, of his thoughts,' &c.). In consequence of the greater courtesy shown towards women of higher rank, arose the custom of prefixing the word *ma* to *dame*, as a special proof of veneration and homage. Hence, too, the Virgin-mother was called in France *Notre Dame* ('Our Lady,' as if no single Christian could exclusively claim the privilege of serving her with the homage of his heart). The daughters of the king of France, as soon as they came into the world, were called *Madame*; and this was also the sole title of the wife of the king's eldest brother. In England the word Dame, though not much used, is now applied to married women of all classes, but has recently acquired a special significance in connection with the Primrose League (q.v.). It is also applied specially to the mistress of a small elementary school, especially if elderly and ignorant. *Madame* is shortened into *Madam*, and vulgarly into *Ma'am* and similar forms.

**Dame's Violet** (*Hesperis*), a genus of Cruciferae, closely allied to stock and wallflower; natives

chiefly of the middle and south of Europe, and temperate Asia. One only, the Common Dame's Violet or Rocket (*H. matronalis*), occurs wild in Britain as a garden escape. The usually lilac-coloured flowers are scentless by day, but very fragrant at night, on which account this plant is cultivated in flower-pots by German ladies. The custom appears to have been an old English one also, and from it the plant derives its technical name. The Night-scented Rocket (*H. tristis*) is also a favourite flower in Germany.

There are many florist's varieties ranging on each side of the familiar lilac tint to purple or white, often also variegated, and single or double.

**Damiani**, PIETRO, a great Italian ecclesiastic of the 11th century, was born in 1007 at Ravenna,

herded swine in his boyhood, but rose by his learning and devotion to the interests of the church to be cardinal and Bishop of Ostia (1057). He supported with vigour the ecclesiastical policy of Hildebrand (afterwards Gregory VII.), without sharing his arrogance and ambition, and was employed in many important missions. He died at Faenza in 1072. His letters, speeches, and other writings were collected by Cardinal Cajetan, and often reprinted (best ed. 4 vols. Ven. 1743). See the Life by Neukirch (Gott. 1875).

**Damianus**, ST. See COSMAS.

**Damien**, FATHER. Joseph Damien, born at Louvain, 3d January 1841, in 1873 devoted himself to the awful duties of spiritual guide to the lepers confined to the Hawaiian island of Molokai. Sent on a mission to Honolulu, where he heard from the bishop the neglected state of the lepers, some 700 or 800 in number, who lived on that small island, he volunteered to establish himself amongst them; and from 1877 onwards became physician of their souls and bodies, their magistrate, teacher, carpenter, gardener, cook, and even gravedigger at need. For long he worked on single-handed at his noble labours, but was ultimately joined by another priest. In 1885 the malady appeared in him; yet he continued unabated his heroic labours till near his death, 10th April 1889. There are lives by Clifford (1889), Cooke (1889), and Father Pamphile (1889); R. L. Stevenson's *Open Letter to the Reverend Dr Hyde* (1890) is a famous appreciation.

**Damiens**, ROBERT FRANÇOIS, the would-be murderer of Louis XV., was born in 1714 near Arras. Already known in his youth as *Robert le Diable*, he was by turns a soldier and a servant in Paris; in 1756 he was forced for a robbery to flee to Belgium, but ventured to return to Paris about the end of the year. Already he had formed the plan to murder the king, either, as he himself alleged, on account of his conduct towards the parliament, or because, as was generally asserted, he was instigated by the Jesuits. On 4th January 1757 he went to Versailles, next day followed the king and his courtiers about everywhere, and about six o'clock at night, when the king was entering his carriage to leave Trianon, managed to stab him. Damiens was seized before he could finish the deed, and was nearly three months later adjudged by the parliament to a horrible death. The hand which had attempted the murder was burned at a slow fire; the fleshy parts of his body were then torn off by pincers, and melted resin and oil poured into the wounds; finally, he was torn to pieces by four horses. The fragments of his body were burned, the house in which he was born pulled down, and his family banished from France for ever.

**Damietta** (Arab. *Dimyat*), a town of Lower Egypt, situated on the right bank of the chief eastern mouth of the Nile, about 8 miles from its mouth in the Mediterranean. It is irregularly but well built, and has some handsome mosques and marble baths, and of course several bazaars. Its commerce has been much injured by the prosperity of Alexandria, but it still carries on a considerable trade in exporting rice, fish (from Lake Menzala), coffee, and dates; and imports charcoal, soap, and manufactured goods. It is the terminus of a branch-railway from Cairo. The cambric (*kasab*) known as *dimity* received its name from Damietta, where it was first manufactured, but it is so no longer (Lane-Poole, *Art of the Saracens*), and the leather-work for which it was famous has also declined. A bar at the mouth of the river prevents vessels of more than fifty or sixty tons burden from ascending to the city. Population, 30,000. The existing town was erected after 1251, but prior to that a city of

Common Dame's Violet (*Hesperis matronalis*).

the same name (more anciently Tamiáthis) stood more to the south. It was strongly fortified by the Saracens, and formed on that side the bulwark of Egypt against the early crusaders, who, however, succeeded in capturing it more than once. It was razed, and rebuilt farther inland on the site it now occupies, by the Mamluk sultan Beybars.

**Dammar**, or **DAMMAR PINE** (*Agathis*, *Dammara*), a genus of Coniferæ, of the family Araucariinæ, distinguished from Araucaria by its laterally winged seeds not being adherent to the carpellary leaf. There are four species, all oriental

Branch of Dammar Pine.

or Australasian, of which the most familiar is *A. (Dammara) orientalis* or *alba* of the lower mountain-regions of the Malay Archipelago, Borneo, and the Philippines, a lofty tree with stout, leathery, lanceolate leaves. The timber is light, but the tree is chiefly valuable for its extraordinary abundance of resin, which is not only obtained in quantity from incisions which are best made in the large knot-like prominences of the lower part of the stem and the root, but which naturally exudes so freely as to form large lumps underground, and

foot-long icicles or stalactite-like masses hanging from the branches. According to Miguel it even drips from the branches in Sumatra in such quantity as often to form incrustations and rock-like masses on the banks of streams. At first semifluid and of pleasant balsamic odour, it soon hardens into an inodorous transparent mass, of no great hardness, but of glossy appearance and conchoidal fracture. It is soluble in cold ether, and at all temperatures in ethereal and fatty oils; but not entirely in boiling alcohol. It is of great value in the preparation of transparent and rapidly drying varnishes. The name signifies in Malay, 'light.' The Kauri Pine (q.v.) of New Zealand is *A. australis*. *D. ovata* of New Caledonia has also similar properties.

The same name is applied in commerce to the resin of other and unrelated trees. Thus the dammar of shipyards is derived from a species of *Canarium*, an Amyridaceous tree, while Black Dammar is a kind of pitch derived from the allied *Marignia*. *Shorea robusta*, a dipteraceous tree, yields pitch and resin used in Indian dockyards, and sometimes also called dammar. Dammar is also occasionally confused with kinds of copal; thus the resin of *Vateria indica* (Dipteracæ) is sometimes known as Dammar or Piny Dammar. It is the source of the Piny Varnish of India. See COPAL.

**Damnatory Clauses.** See ATHANASIAN CREED.

**Damocles**, one of the courtiers and flatterers of the elder Dionysius, tyrant of Syracuse. Cicero tells how Damocles, having extolled in the highest terms the grandeur and happiness of royalty, was reproved by Dionysius in a singular manner. The sycophant was seated at a table, richly spread and

surrounded by all the furniture of royalty, but in the midst of his luxurious banquet, on looking upwards, he saw a keen-edged sword suspended over his head by a single horse-hair—a sight that at once altered his views of the felicity of kings.

**Damodar**, a river of India, rises in the Chutia Nagpur watershed, and after a south-easterly course of 350 miles enters the Hugli from the right. The valley of the Damodar abounds in coal and iron.

**Damoh**, a town of India, in the Jabalpur (Jubbulpore) division of the Central Provinces, 50 miles E. of Sagar, with 17,000 inhabitants.—The district of Damoh has an area of 2800 sq. m., and a pop. of about 333,000.

**Damon and Pythias** (more correctly Phintias), two noble Pythagoreans of Syracuse, remembered as the models of faithful friendship. Pythias, having been condemned to death by the elder Dionysius, the tyrant of Syracuse, begged to be allowed to go home for the purpose of arranging his domestic affairs, Damon pledging his own life for the reappearance of his friend at the time appointed for his doom. Dionysius consented, and Pythias returned just in time to save Damon from death. Struck by so noble an example of mutual affection, the tyrant pardoned Pythias, and desired to be admitted into the sacred fellowship.

**Damper**, a door or valve which, by sliding, rising and falling, turning on a hinge, or otherwise, diminishes the aperture of a chimney or air-flue; this lessens the quantity of air that can pass through a furnace or other fire, and thus 'damps' or checks the combustion.—The damper of a piano-forte is that part of the mechanism which, after a key is struck and the finger is lifted up from the key, immediately checks or stops the vibration of the string, unless prevented by the use of the pedal (see PIANOFORTE). The mute used with the horn and other brass instruments is also called a damper.

—Damper is also the name given in Australia to a simple kind of unleavened bread formed of wheat-flour. It is made by travellers in the bush, and baked among the ashes of a fire often kindled for the purpose.

**Dampier**, the name of several places in Australasia: (1) Dampier Archipelago, a cluster of about twenty small rocky islands off the NW. coast of Australia, in 21° S. lat., and 117° E. long., divided by the Mermaid Strait in two groups; in the eastern is Rosemary, the largest island.—(2) Dampier Island, off the NE. coast of New Guinea, with a volcano about 5250 feet high.—(3) Dampier's Land, a peninsula of Western Australia, fertile and well watered, lying between King Sound and the Indian Ocean.—(4) Dampier Strait, between New Guinea and the archipelago of New Britain, forming, with Goschen Strait to the SE., the shortest route from Eastern Australia to China by some 300 miles.—(5) Dampier Strait, separating the island of Waygiu from the NW. end of New Guinea, the easiest passage between the Indian and Pacific oceans.—(6) Mt. Dampier, S. Island, New Zealand (q.v.).

**Dampier**, WILLIAM, a celebrated English navigator and hydrographer, was born near Yeovil in Somersetshire in 1652. He went early to sea, saw much hard service, and gained a great knowledge of hydrography in voyages to Newfoundland, Bantam, Jamaica, and the Bay of Campeachy. After spending a short time among the lawless log-wood-cutters on the coast of Yucatan, where honest trade was pleasantly varied with private piracy, he joined in 1679 a regular party of buccaneers who crossed the Isthmus of Darien, sacked Santa Marta, and ravaged the coast as far south as the island of Juan Fernandez. In 1683 he engaged in another

buccaneering expedition, in which he coasted along the shores of Chili, Peru, and Mexico, sailing thence across the Pacific, and touching at the Philippine Islands, China, and New Holland. Put ashore on Nicobar Islands, May 1688, after a dispute with his comrades, he made his way by sheer seamanship in a native canoe to Atcheen, and after two years' trading in the neighbouring seas, got back to England (1691), where he published his vigorous and interesting *Voyage round the World* (1697). He was afterwards deputed by government to conduct a voyage of discovery to the South Seas, in which he explored the west and north-west coasts of Australia, also the coasts of New Guinea and New Britain, giving his name to the Dampier Archipelago and Strait. On the return voyage his vessel was wrecked off Ascension, and Dampier with his crew lived on turtles and goats on that island for over five weeks, until relieved. The old buccaneer was more skilful as a pilot than successful as a commander, and his overbearing cruelty to his lieutenant led to himself being court-martialled. Yet soon after he was again appointed to the command of two vessels in a privateering expedition to the South Seas. He was as unfortunate as before. According to an account published by Funnell, one of his sailors, Dampier was guilty not merely of drunkenness and brutality, but even of cowardice, which at least is hard to believe of an old buccaneer. The sailing-master of one of his ships was that Alexander Selkirk who was marooned at Juan Fernandez, and was yet to be made immortal as Robinson Crusoe. Dampier returned home at the close of 1707, poor and broken, nor did his angry *Vindication* re-establish his reputation. Next year he sailed again to the South Seas as pilot to a privateer, which rescued Selkirk, and returned in 1711 after a prosperous voyage. Dampier died in London early in March 1715. See *Life* by Masefield (1907).

**Damping off**, in Horticulture, the death of plants from excess of moisture in the soil and atmosphere. Young seedlings in stoves and hotbeds are particularly liable to it. The cause is a parasitic fungus, *Pythium*. Prevention is not always easy; not only because some plants are very sensitive as to moisture, but also because the necessity of keeping sashes closed on account of temperature often stands in the way of the ventilation which would otherwise be desirable, and it is when a moist atmosphere stagnates around them, and the temperature is not very low, that plants are most liable to damp off.

**Damson**, a rather small oval-fruited variety of the common plum, much esteemed for preserving, and not wholly unfit for dessert. The tree grows to a considerable height, but has a bushy, sloe-like appearance. It is extremely fruitful. There are many sub-varieties, with fruit of different colours, dark purple, bluish, black, yellow, &c. Damsons grow in great quantities in some parts of England. Damson pies and damson cheese—made somewhat in the manner of fig-cake—are well known. The name is a corruption of *Damascene*, from Damascus.—The Mountain or Bitter Damson of the West Indies is the Simaruba (see SIMARUBACEÆ).

**Dana**, CHARLES ANDERSON, an American man of letters, was born at Hinsdale, New Hampshire, 8th August 1819, spent two years at Harvard, and was a member of the Brook Farm (q.v.) community. From 1848 to 1862 he was the managing editor of the *New York Tribune*, which he was largely instrumental in making the leading organ of the party opposed to the extension of slavery to new territories; and from 1863 to the close of the war he was assistant-secretary of war. In 1867 he purchased the *New York Sun*, and commenced the

successful management of that journal on democratic lines. He published several translations and anthologies, collaborated in a *Life of Giant* (1868), and, along with George Ripley (q.v.), planned and edited the *New American Cyclopædia* (1857-63), and its revised edition, the *American Cyclopædia* (1873-76; see ENCYCLOPÆDIA). He died on the 18th October 1897. See his *Life* by James Wilson (1907).

**Dana**, JAMES DWIGHT, an American mineralogist and geologist, was born at Utica, New York, 12th February 1813. He graduated at Yale College in 1833, and was sent out in 1838 as a scientific observer in the United States exploring expedition, under Wilkes, visiting the Antarctic and Pacific. During the course of this expedition Dana's ship was wrecked. He was afterwards associated with his father-in-law, the elder Silliman, in the editorship of the *American Journal of Science*. In 1846 he was elected professor of Natural History and Geology in Yale College. Among his works are a *System of Mineralogy* (1837), a *Manual of Mineralogy* (1848), two treatises on Coals, a *Text-book of Geology* (1864), *Hawaiian Volcanoes* (1890), and many reports on geological, mineralogical, and zoological subjects. He died 14th April 1895. See his *Life* by Gilman (1899).—His son, EDWARD SALISBURY DANA, born 1849, was professor of physics at Yale (1890-1917), and has written on mineralogy.

**Dana**, RICHARD HENRY, an American poet and prose writer, was born at Cambridge, Massachusetts, 15th November 1787. He was educated at Harvard College, and was admitted to the bar at Boston in 1811. In 1818 he became associate editor of the *North American Review*, to which he contributed largely. Some of his poems, such as *The Dying Raven* (1821), and *The Buccaneer* (1827), were warmly praised by critics on both sides of the Atlantic. The American public, however, received them coldly, partly because it was not at that time educated up to the standard of Dana's work, but chiefly because that work, with all its literary merits, such as learning, neatness of execution, and precision in verbal expression, lacked the elements which most appeal to the popular feelings. Dana's best literary work was done in the field of criticism. His abilities as a critic were very decided; and though many of his best efforts were not duly appreciated in his day, they did much to educate and elevate the literary taste of New England. A collection of his prose and verse appeared in 1833. He was for a time in 1821-22 connected with *The Idle Man*, a meritorious though ill-supported literary periodical. He died at Boston, 2d February 1879.—His son, RICHARD H. DANA, author and lawyer, was born 1st August 1815, and graduated at Harvard College in 1837. During an interval in his collegiate career, occasioned in part by a troublesome affection of the eyes, he shipped as a common sailor, and made a voyage to California and back. This voyage he described in *Two Years before the Mast* (1840), the best book of the kind in the language; in 1840 he was admitted to the Massachusetts bar. As a lawyer he attained great distinction, especially in the department of maritime law. Among his works are *The Seaman's Friend* (1841) and *To Cuba and Back* (1859). He also published an edition of Wheaton's *International Law*, and was prominent as a Free-soiler and Republican. In 1879 he was nominated minister to England, but after a long contest the senate failed to confirm the appointment. He died in Rome, 7th Jan. 1882. See *Life* by C. F. Adams (2 vols. 1890).

**Danaë**, the daughter of Acrisius, king of Argos, herself the great-grandson of Danaus. An oracle had announced that she would one day give birth to a son, who should kill his grandfather. Acrisius,

for safety's sake, shut her up in a dungeon, where, nevertheless, she was visited by Zeus in a shower of gold, and so became the mother of Perseus. Acrisius next put both the mother and child into a chest, and exposed them on the sea. The chest, however, drifted ashore on the island of Seriphos, and Danaë and her child were saved. She remained in the island until Perseus (q.v.) had grown up and become a hero famous for his exploits; afterwards she accompanied him to Argos. On his arrival, Acrisius fled, but was subsequently slain accidentally by Perseus at Larissa.

**Danākīl** (singular *Dankālī*), the Arabic and now general name for the numerous nomad and fisher tribes inhabiting the coast plains of north-east Africa, between the Abyssinian highlands and the Red Sea, from Massowah south to Tajurrah Bay. They belong to the Ethiopic Hamites, are akin to the Gallas and Somalis, and call themselves Afar, and are well built and slender. The greater part of their country is (nominally) a province of Abyssinia, but there are many of them in Eritrea and French Somaliland. Formerly piratical, they are now peaceful fishermen, and are skilful in catching the dugong.

**Danaüs**, in Greek Mythology, the son of Belus and twin-brother of Ægyptus, originally ruler of Libya. Fearing his brother, he fled to Argos, with his fifty daughters, the Danaides, and here he was chosen king, in place of Gelanor. The fifty sons of Ægyptus followed him, and under the pretence of friendship, sought the hand of his daughters in marriage. Danaus consented, but on the bridal night he gave his daughters each a dagger, and urged them to murder their bridegrooms in revenge for the treatment he had received from Ægyptus. All did so, except one, Hypermeestra, who allowed her husband, Lynceus, to escape. The poets tell how in the under-world the Danaides were compelled, as a punishment for their crimes, to pour water for ever into a vessel full of holes. From Danaus, the Argives were called Danai.

**Danbury**, one of the capitals of Fairfield county, Connecticut, 69 miles NNE. of New York, has some forty manufactories of felt hats (the chief industry), and produces also machinery, paper boxes, and silver-plate. Pop. (1880) 11,666; (1900) 16,537; (1910) 20,234; (1921) 18,943.

**Danby**, FRANCIS, A.R.A., landscape-painter, was born near Wexford, Ireland, 16th November 1793. In 1812 he began to exhibit in Dublin; in 1813, with O'Connor and George Petrie, afterwards president of the Hibernian Academy, he went to London. At Bristol, on the return journey, the means of the party were exhausted, and Danby settled in that city, where he resided till 1824. His 'Upas Tree,' a large and impressive work, now in the South Kensington Museum, was exhibited in the British Institution (1820); his 'Disappointed Love,' in the Academy (1821), as also his 'Delivery of the Israelites out of Egypt' (1825), which gained him his election as an associate. In 1828 his 'Opening of the Sixth Seal' won a premium of £200 at the British Institution; in the following year two other important subjects from the Apocalypse appeared in the Academy. At this time a disagreement arose between the artist and the Academy, which, along with other reasons, led to his leaving England. For eleven years he resided on the Continent, mainly in Switzerland, painting little, and amusing himself with boating. On his return to England, he took up his residence at Exmouth, and contributed very regularly to the Academy till his death on 9th February 1861. His 'Fisherman's House, Sunset' (1846), is now in the National Gallery. His works, of which several have been engraved, are distinguished by

imagination and poetic feeling. His three sons, John, Thomas, and James Francis, were all landscape-painters. The last named was born at Bristol in 1816, and died in London, 22d October 1875.

**Danby**, LORD. See LEEDS, DUKE OF.

**Dance**, GEORGE (1700-68), architect, designed the Mansion House (1739) and many other London buildings.—His son, GEORGE DANCE, the younger (1741-1825), rebuilt Newgate (1770-83), and was one of the original Royal Academicians.

**Dance of Death** (Lat. *Chorea Machabæorum*, Fr. *La Danse Macabre*), a name given to a certain class of allegorical representations, illustrative of the universal power of death, and dating from the 14th century. When the introduction of Christianity first banished the ancient Germanic conception of a future state, a new description of death-mythology arose, partly out of biblical sources, partly out of the popular character itself, wherein the Last Enemy was represented under simple and majestic images, such as that of a husbandman watering the ground with blood, ploughing it with swords, sowing it with corpses, rooting out weeds, plucking up flowers, or felling trees; or of a monarch assembling his armies, making war, taking prisoners, inviting his subjects to a festival, or citing them to judgment. But with a gradual change in national manners came a change in the mode of treating the subject, and it was associated with everyday images, such as the confessional, chess-playing, and above all, with the adjuncts of a festival—viz. music and dancing. This tendency to familiarise the theme increased during the confusion and turmoil of the 14th century, when the national mind alternated between fits of devotion and license, or blended both elements in satire and humour. Such a mood as this naturally occupied itself with personifying Death, and adopted by preference the most startling and grotesque images it could find—that of a musician playing to dancing-men, or a dancer leading them on; and as the dance and the drama were then intimately connected, and employed on religious occasions, this particular idea soon assumed a dramatic form.

This drama was most simply constructed, consisting of short dialogues between Death and four-and-twenty or more followers, and was undoubtedly enacted in or near churches by religious orders in Germany during the 14th century, and at a rather later period in France. It would appear that the seven brothers, whose martyrdom is recorded in the 7th chapter of the 2d Book of Maccabees, either played an important part in the drama, or the first representation, which took place at Paris in the Monastery of the Innocents, fell upon their festival, and hence the origin of the ancient name, *Chorea Machabæorum*, or *La Danse Macabre*. As early as 1400, the dramatic poem was imitated in Spain, and appears there in seventy-nine strophes of eight lines each (*La Dança General de los Muertos*), but it did not spread; while the French, having a love for pictorial representation, very early affixed an illustration to each strophe, and in 1425 painted the whole series on the churchyard wall of the Monastery of the Innocents, where the Dance of Death was habitually enacted. We find the subject treated in painting, sculpture, and tapestry, in the churches of Anjou, Amiens, Angers, Rouen, to say nothing of the numerous woodcuts and accompanying letterpress which succeeded the invention of printing. From Paris, both poem and pictures were transplanted to London (1430), Salisbury (about 1460), Wortley Hall in Gloucestershire, Hexham, &c.

But nowhere was the subject so variously and strikingly treated as in Germany. A picture in one of the chapels of the Marienkirche, at Lübeck,

still, in spite of repeated re-paintings, bearing the unmistakable impress of the 14th century, exhibits the very simplest form of the drama, and has some Low-German verses attached to it. Here we see twenty-four figures, partly clerical, partly lay, arranged in a descending scale, from the pope himself down to a little child, and between each of them a dancing figure of Death, not in the form of a skeleton, but a shrivelled corpse, the whole being linked in one chain, and dancing to the music of another Death. This representation is almost the same as a very ancient one at La Chaise-Dieu, in Auvergne, and points to the identity of the original dramatic spectacle in both countries.

The celebrated Dance of Death on the cloister walls of the Klingenthal, a convent in Basel, though painted probably not later than 1312, exhibited a departure from the simplest form—the number of persons exceeding the original twenty-four, and the chain being broken up into separate couples. But both alike are only to be regarded as scenes from a drama, and cannot, therefore, be justly compared with a painting in the Pisan Campo Santo, the 'Triumph of Death,' ascribed to Andrea Orcagna. And the acted drama enduring till the 15th century, we find that while there were varieties in the paintings, the poem, which was the most important feature, remained almost unchanged.

About the middle of the 15th century, however, the drama being altogether laid aside, the pictures became the main point of interest, the verses merely subsidiary. Accordingly, we find from this time the same pictures repeated in different places, with different verses, or no verses at all, till at length both verses and pictures entirely change their original character. The Dance of Death being transferred from the quiet convent walls into public places, gave a new impulse to popular art. Duke George of Saxony had, in 1534, the front of his Dresden castle ornamented with a life-size bas-relief of the subject, and other representations are to be found at Strasburg and Bern. There was a Dance of Death painted round the cloister of old St Paul's in London, in the reign of Henry VI.; and there is a sculptured one at Rouen, in the cemetery of St Maclou. But Holbein has the credit of availing himself most effectively of the original design, and giving it a new and more artistic character. Departing from the idea of a dance, he illustrated the subject by fifty-three distinct sketches for engravings, which he called 'Imagines Mortis.' The originals of these are at Petrograd, and reproductions of them have been frequently made. There is a famous Dance of Death at Coire. In the 19th century Kaulbach and Rethel (in satires against the French republic of 1848; text in verse by Reinick, 13th ed. 1902) worked at the subject; Rowlandson and Dr Syntax produced an English *Dance of Death* (1815; new ed. 1904). In pure literature, Goethe's *Totentanz* is memorable; in music, Saint Saens gave notable expression to the idea in his *Danse Macabre*, a symphonic piece with xylophone effects.

See Peignot's *Recherches sur les Danses des Morts* (1826); Massman's *Basler Todtentanz* (1847); Langlois's *Les Danses des Morts* (1851); Douce's *Dance of Death* (1833); Seelmann's *Die Totentanz des Mittelalters* (1893).

**Dancing**, an exercise or amusement in which one or more persons make a series of more or less graceful movements with measured step in accord with music. In its earliest forms among simple races it is a mode of outward expression for strong emotions of joy and sorrow, love and rage, and even for the most solemn and impassioned religious feelings; in more civilised strata of human society it becomes a mere frivolous amusement with no high signification whatever. Dancing corresponds to a universal primitive instinct in man.

It is still practised by the South Sea Islanders, the forest Indians of Brazil, the Zulus, the negroes of Central Africa, and the native Australians, exactly as it was in the earlier stages of every civilised modern race. Many of the rude courting dances of modern savages, like the native Australian *corro-boree*, are themselves refinements of more ancient dances, in the survivals of which we can guess at their original grossness and obscenity. Ferocious war-dances were constantly practised by savage warriors, as the North American Indian braves, who worked themselves up into frantic mechanical intoxication capable of carrying them irresistibly on to victory. The Zulu war-dance is still a noble exercise for warriors, like the Pyrrhic dance of the ancient Spartans; and the dancing and spinning dervishes in the East, who work themselves into spasms of physical excitement, are still highly esteemed for devoutness and piety. Into savage dancing, moreover, the idea of magic always enters. Thus the Mandan Indians dance buffalo to bring game when supplies of food are low, the rain-doctors of Central Africa dance mystic dances to bring down rain, and the wives of Gold Coast negroes dance a battle-dance to give their absent husbands courage in the battle. Everywhere in ancient religions is dancing one of the chief acts of worship. Religious processions went with song and dance to the Egyptian temples; the Cretan chorus, moving in measured pace, sang hymns to the Greek god, Apollo; and one of the Muses (Terpsichore), themselves daughters of Zeus, was the especial patroness of the art. The Phrygian Corybantes danced in honour of Rhea to drum and cymbal; at Rome, during the yearly festival of Mars, the Salian priests sang and danced, beating their shields; among the ancient Jews, Miriam danced to a song of triumph—itself an act of worship, and David danced in procession before the Ark of God. A survival of religious dancing is still seen even within the pale of Christendom, where during the Corpus Christi Octave a ballet is danced every evening before the high altar of Seville Cathedral, by boys from twelve to seventeen years of age, in plumed hats and the dress of pages of Philip III.'s time.

Dancing and imitative acting in the lower stages of civilisation are identical, and in the sacred dances of ancient Greece we may trace the whole dramatic art of the modern world. Aristotle ranked dancing with poetry, and Pindar applies the name of the dancer even to Apollo. The dancing-master in *Le Bourgeois Gentilhomme* asserts that the destinies of the nations depend on the science of dancing; and Lucian, in a well-known dialogue, proves that the art is superior to tragedy, and coeval with the world itself. Sir John Davies, in his long poem, the *Orchestra*, illustrates the origin and importance of dancing, tracing in it all the motions of nature:

For what are breath, speech, echoes, music, winds,  
But dancings of the ayre in sundry kinds.

The Spartans practised dancing as a gymnastic exercise, and made it compulsory upon all children from the age of five. Cicero says, 'No one dances sober unless he chances to be mad;' and indeed sedate Romans in general considered it disgraceful for a free citizen to dance, except in connection with religious ceremonies, but willingly enough witnessed the performances of professional dancers, like the *Almé* of modern Egypt, and the Bayaderes or Nautch girls of India. The early Christians practised choral dances, which came into discredit with the love-feasts or *Agapæ*. St Augustine says, 'it is better to dig than to dance,' and many of the Fathers condemned the practice as vigorously as our Puritan ancestors, who

saw deadly sin in 'promiscuous dancing.' St Chrysostom says dancing came first from the devil, and Father Mariana tells us the famous *saraband* worked more mischief than the plague. The *fundango* was hotly condemned by the clergy, but when danced before the Sacred College, who wished to see it before finally prohibiting it, so charmed the grave judges that they gave it their unanimous approval. Many of the medieval dances were solemn and stately in character, like the *danses basses*, which were danced to psalm-tunes at the court of Charles IX. of France; while it was not uncommon to see the princes of the church themselves treading a measure, and it is said the whole august Council of Trent danced at a ball given in 1562 to King Philip II. of Spain. The more lively *galliarde* and *volta* were introduced into France from Italy by Catharine de' Medici, but it was not till the reign of Louis XIV., himself an enthusiastic dancer and performer in the court ballets until cured by some verses about Nero in Racine's *Britannicus*, that dancing reached its height in France. A Royal Academy of Dancing was founded in 1662, at the head of which was the famous Beauchamps, from whom the king took a dancing lesson every day for twenty years. Later great dancing-masters in France were Pécour, Marcel, and Noverre. Among dances that successively were paramount in society in France were the graceful *minuet*, the favourite for a century; the *quadrille* or *contre-danse*, often connected erroneously with the English country-dance; the *Écossaise*, first introduced in 1760; the *galop*, a death-blow to the 'poetry of motion,' introduced from Germany; the *cotillon*, fashionable under Charles X.; the *polka*, first danced at the Odéon in 1840 by a dancing-master from Prague; the *polka tremblante*, or *schottisch*, also of Bohemian origin, first brought out in Paris in 1844; the *lancers*, introduced by Laborde in 1836; the *waltz*, originally Bavarian, now considerably modified; the South American *tango*, also modified in Paris. Society everywhere in Europe has followed the lead of the French, and latterly of the Americans (*two-step*, *fox-trot*, &c.). The people, however, have preserved their own old national dances, and these are still danced in every corner of Europe, stamped everywhere with as distinct an impress of nationality as the grave Basque *mutchiko*, or the *cachucha*, the *fundango*, and *bolero* of southern Spain. Characteristic again of particular races or merely of classes of people are such forms as the Scottish *reel*, *Highland-ling* and *strathspey*, the Irish *jig*, *nigger break-downs* and *cake-walks*, sailors' *hornpipes*, *step-dances*, *morris-dances*, and the like. In ballet dancing Adeline Genée predominated for many years, but her method was eclipsed by Isadora Duncan and then by the Russian ballet, represented by Nijinsky, Fokine, Pavlova, and Karsavina, helped by the art of Bakst.

See BALLET, WALTZ, STRATHSPEY, &c.; Crawford Flitch, *Modern Dancing and Dancers* (1911); Giraudet, *Traité de la Danse* (1900); W. A. Propert, *The Russian Ballet* (1921), Cecil Sharp and A. P. Oppé, *The Dance* (1925); Soria, *Histoire de la Danse* (1897); E. Scott, *Dancing in all Ages* (1899); Vuillier, *The History of Dancing* (trans. 1897).

**Dancing Mania**, an epidemic disorder allied to Hysteria (q.v.). Imposture was often present, and the consequences often clearly showed impure motives; but there is also evidence that in many cases the convulsive movements were really beyond the control of the will, whatever may have been the original character of the motives that prompted them. Epidemics of this sort were common in Germany during the middle ages, and are formally described as early as the 14th century; in Italy, *tarantism*, a somewhat similar disease, was ascribed

to the bite of a spider called the *Tarantula* (q.v.); and similar convulsive affections have been witnessed in Abyssinia and India, and even in comparatively modern times and in the most civilised countries in Europe, under the influence of strong popular excitement, especially connected with religious demonstrations. But the true dancing mania of the middle ages had its theatre chiefly in the crowded cities of Germany.

In July 1374 there appeared at Aix-la-Chapelle assemblies of men and women, who, excited by the wild and frantic, partly heathenish, celebration of the festival of St John, began to dance on the streets, screaming and foaming like persons possessed. The attacks of this mania were various in form, according to mental, local, or religious conditions. The dancers, losing all control over their movements, continued dancing in wild delirium, till they fell in extreme exhaustion, and groaned as in the agonies of death; some dashed out their brains against the walls around. When dancing they were insensible to external impressions, but haunted by visions, such as of being immersed in a sea of blood, which obliged them to leap so high, or of seeing the heavens open, and the Saviour enthroned with the Virgin Mary. The frenzy spread over many of the towns of the Low Countries. Troops of dancers, inflamed by intoxicating music, and followed by crowds, who caught the mental infection, went from place to place, taking possession of the religious houses, and pouring forth imprecations against the priests. The mania spread to Cologne, Metz, and Strasburg, giving rise to grave disorders, impostures, and profligacy. These countries were generally in a miserable condition; and arbitrary rule, corruption of morals, superstition, and insecurity of property, had already prepared the wretched people, debilitated by disease and bad food, to seek relief in the intoxication of an artificial delirium. Exorcism had been found an efficacious remedy at the commencement of the outbreak; and in the beginning of the 16th century, Paracelsus, that great reformer of medicine, applied immersion in cold water with great success. At the beginning of the 17th century it was already on the decline; it still occurs in single cases as a sort of nervous affection, and an epidemic outbreak was reported from the Troad in 1911. See CHOREA, CONVULSIONARIES, EPIDEMIC, TARANTULA, VITUS (St).

**Dancourt**, FLORENT CARTON, a French dramatist, born in 1661. At one time an actor and a favourite of Louis XIV., he became devout in his old age, which he spent in retirement in the country. He died in 1725. He was a prolific author, and excelled in depicting the stupidity of the peasantry and the follies of the *bourgeoisie*. Of his plays the best are *Les Bourgeoisies de Qualité*, *Le Chevalier à la Mode*, *Le Galant Jardinier*, and *Les Trois Cousines*.

**Dandelion** (*Taraxacum officinale*, formerly *Leontodon Taraxacum*) is a ligulifloral composite, common in several varieties or sub-species throughout Britain and the whole of Europe, in pastures and by waysides, and now also so perfectly naturalised in many parts of North America as to be there one of the most familiar spring-flowers. The names *Dandelion* and *Leontodon* (Fr. and Gr., 'lion's tooth') both have reference to the form of the leaves. The whole plant abounds in a milky juice, containing a peculiar crystalline principle called *Taraxacin*; has a bitter taste, and valuable medicinal properties. Roasted and ground, dandelion-root is sometimes used as a substitute for coffee. *Dandelion Coffee*, however, is usually a mixture of ordinary coffee and the powder or extract of dandelion-root; and *Dandelion Chocolate* is composed of

one part of common chocolate and four parts of the powder of dandelion-root. The young leaves, when blanchéd, are a good salad, resembling lettuce or endive.

**Dan'dolo**, a famous Venetian family, which gave four doges to the republic. The most illustrious of its members was Enrico, born about 1110 or 1115 A.D. Eminent in learning, eloquence, and knowledge of affairs, he ascended from one step to another, until, in 1173, he was sent as ambassador to Constantinople, and in 1192 was elected doge. In this latter capacity he extended the bounds of the republic in Istria and Dalmatia, defeated the Pisans, and, in 1201, marched at the head of the crusaders. He subdued Trieste and Zara, the coasts of Albania, the Ionian Islands, and Constantinople, 17th July 1203. When the Emperor Alexius was murdered by his own subjects, Dandolo laid siege to Constantinople, and took it by storm, 13th April 1204. He established there the empire of the Latins, and caused Count Baldwin of Flanders to be chosen emperor. By his exertions Venice obtained possession of several Greek islands and large territories in Greece. Dandolo died at Constantinople, 1st June 1205. See CRUSADES, VENICE.—Giovanni Dandolo was doge, 1280-89; Francesco, 1328-39; Andrea, 1342-54.

**Dandriff**. See PITYRIASIS.

**Dandy**, or **DANDIE**. See TERRIER.

**Dandy Fever**. See DENGUE.

**Danebrog** ('Danish banner'), the second of the Danish Orders of Knighthood (q.v.).

**Danegeld**, a tax levied on land, originally to buy off the Danes. It was first raised by Ethelred II., was abolished by Edward the Confessor, reimposed at a higher rate by the Conqueror, and finally abolished under Henry II.

**Dane-lagh** (*Danelaw* or *Denalagu*), the name applied to that part of England in which Danish influence was at one time paramount, and which still shows in popular place-names a distinct Danish impression. At various times it ranged along the coast counties from Yorkshire to Essex. The southern part of Deira was the most thoroughly Danish part of the whole, and here the typical Danish endings for place-names, *thorpe*, *caster*, and *by*, are still the most common. Next to Yorkshire came Lincoln, with Lindsey for its centre. The least Danish part was East Anglia and Essex. Deira and Lindsey were divided into *ridings*, and these into *wapentakes*. See NORTHMEN, ENGLAND.

**Danes' Dyke**. See FLAMBOROUGH HEAD.

**Dangerfield**, THOMAS (1650-85), false witness, and inventor of the Meal-tub Plot (q.v.).

**Dángs**, THE, a hilly tract in the Surat Political Agency (area, c. 1000 sq. m.; pop. 18,000, of wild forest tribes). Densely wooded and shut in by steep hills, with heavy rainfall and close atmosphere, it is singularly unhealthy. The Bhils (q.v.), the most important tribe, are the police, and have charge of the district treasuries. The products are teak and other timber.

**Daniel**, THE BOOK OF, claims to give an account of the career and prophetic utterances of Daniel, who had been carried as a captive to Babylon after the fall of Jerusalem in 586 B.C., during the reigns of Nebuchadnezzar, Darius, and Cyrus. There is a reference to a Daniel in Ezek. xiv. 14-20 and xxviii. 3, who is held up along with Noah and Job as an example of righteousness, but as these two chapters are generally dated in 594 B.C. and 588 B.C. respectively, it is difficult to see how the Daniel of Ezekiel can be identified with the hero of the Book of Daniel, as according to the latter he would have been quite a youth in 588 B.C., and

could not possibly have attained sufficient renown to be ranked with Job and Noah. The Book of Daniel is written partly in Hebrew and partly in Aramaic. It is composed of two elements—narrative and prophecy. The prophetic sections constitute the kernel of the book, and form the first example of pure apocalyptic in Jewish literature. They give under various symbols and figures a rough outline of the characteristic features of the Babylonian, Median, Persian, and Greek empires, and cover in their outlook a period of more than 400 years from 586 B.C. to 165 B.C. The traditional view that the Book of Daniel is a contemporary record of the life and teaching of its hero is now abandoned by the majority of modern scholars on the following grounds. (1) If the traditional theory had been true the book would have been placed in the second canon of the Old Testament—i.e. the prophetic writings—whereas it was assigned a place in the third canon—i.e. the Hagiographa (see BIBLE, 'The Formation of the Old Testament Canon'). (2) The style is much later than the Babylonian period. The use of Aramaic, the introduction of Persian and Greek 'loan-words,' the frequent occurrence of later Hebrew forms and constructions, all seem to make the traditional view impossible. (3) In the earlier part of history, during the period when Daniel was living at the Babylonian court, the writer is guilty of several flagrant historical blunders. He assumes, for instance, the existence of a Median empire between the Babylonian and the Persian, whereas the evidence of all our other authorities regards the Persian empire as the immediate successor of the Babylonian. The figure of 'Darius the Mede' seems to be purely mythical. Belshazzar was never king of Babylon, as the book frequently describes him. On the other hand, when the writer approaches the Greek period his utterances are wonderfully accurate even in the smallest details. All these facts point to the conclusion, which is now generally accepted, that the book is the product of the Maccabean age, and was written between 168 and 165 B.C. to encourage the Jewish nation in its resistance to Antiochus Epiphanes. Read in the light of the facts connected with Antiochean persecution, the book becomes luminous, and we are able to appreciate the influence which it must have exerted, and to understand the reasons which led to its inclusion in the canon.

The most useful English commentaries are Bevan's, Driver's, Charles's. The best representatives of the traditional view are Pusey, *Daniel the Prophet* (1864); Wright, *Daniel and its Critics* (1906). See APOCALYPTIC WRITINGS.

**Daniel**, SAMUEL, poet, was the son of a music-master, and was born in 1562 near Taunton, Somersetshire. He entered Magdalen Hall, Oxford, in 1579, but 'his glory being more prone to easier and smoother studies than in pecking and hewing at logic,' quitted the university without taking a degree. He was some time tutor at Wilton to William Herbert, son of the Earl of Pembroke and Sir Philip Sidney's sister; afterwards at Skipton to Anne Clifford, daughter of the Earl of Cumberland. In 1603 he was appointed to read new plays, and twelve years later he had for some time charge of a company of young players at Bristol. In 1607 he became one of the queen's grooms of the privy chamber. Towards the close of his life he retired to a farm which he possessed at Beckington, in his native county, where he died in October 1619. Daniel was highly praised by his contemporaries, as Lodge, Carew, Drummond of Hawthornden, although Ben Jonson described him as 'a good honest man . . . but no poet,' and Drayton quotes the opinion of some wise men that he was 'too much historian in verse.'

besides saying for himself that 'his manner better fitted prose.' Of modern critics, Coleridge, Lamb, and Hazlitt unite in praising him. As a sonneteer Daniel is altogether admirable. Some of the 'Delia' series rank near the best examples of this form in English. Daniel is indeed an elegant if not a great poet. His writings are pervaded by a moral thoughtfulness and purity of taste remarkable indeed, but lacking that vital energy of movement and memorableness of expression which spring from genuine inspiration. The 'well-languaged Daniel' is therefore not the most interesting of the Elizabethans, although his style is quite modern. His works include sonnets, epistles, masks, and dramas; but his chief production is a poem in eight books, entitled *A History of the Civil Wars between York and Lancaster*. His *Defence of Ryne* (1602) is written in admirable prose. Dr Grosart reprinted Daniel's works in the Huth Library (5 vols. 1885-96).

**Daniell**, JOHN FREDERIC, scientist, was born in London, March 12, 1790. He was for a time engaged in a sugar-refining work, but was elected a Fellow of the Royal Society in 1814, and devoted himself to chemistry and meteorology. In 1823 he published his *Meteorological Essays*, and in 1824 the Horticultural Society awarded him their silver medal for an essay on artificial climate. In 1831 he was appointed professor of Chemistry in King's College, London; and in 1839 published his *Introduction to Chemical Philosophy*. He invented a hygrometer (1820), and a new pyrometer (1830), as well as the electric battery known by his name; and he wrote many valuable papers. He died March 13, 1845.

#### Danish Literature. See DENMARK.

**Danites**, or DESTROYING ANGELS, a secret society founded by Joseph Smith in 1838, professedly merely for the defence of the Mormon sect against the mob. The members, originally some 300 in number, were bound by an oath, under penalty of death, to sustain the 'first presidency' and one another in all things, and special 'destruction companies' were appointed for the purpose of burning and destroying, at first by way of reprisal. Remembrance of the society's operations was revived by the trial, conviction, and execution of Bishop John D. Lee, in 1877, for instigating the massacre of a train of 140 non-Mormon emigrants at Mountain Meadow, twenty years before.

**Dannecker**, JOHANN HEINRICH VON, a sculptor who in respect of date and art stands between Canova and Thorwaldsen, was born at Waldenbuch, in the district of Stuttgart, 15th October 1758. His parents were in very humble circumstances; but through the favour of the Duke of Württemberg, he received a good education at the military academy at Ludwigsburg. His artistic talents were rapidly developed. In 1780 he obtained the prize for the best model of 'Milo'; and in 1783 went to Paris, where he studied for two years; after which he returned to Rome, where he met Goethe, Herder, and Canova. At Rome Dannecker remained till 1790, becoming afterwards professor of sculpture in the Academy of Stuttgart. He died 8th December 1841. 'Ariadne on the Panther' (1816; at Frankfurt), a Christ at Moscow (1824), and his busts of Schiller, Gluck, and others are masterpieces.

**Dannevirke** ('Danes' work'), the rampart built by the Danes about 808 across Sleswick, just north of the Eider; the scene of fighting in 1849, and razed by the Germans in 1850.

**D'Annunzio**, GABRIELE, novelist and poet, was born of Dalmatian stock in 1863, at Francavilla, near Pescara, and began to write verse while

still at school in Tuscany; publishing between 1879 and 1886 half-a-dozen volumes of verse and of stories, which attracted by their grace and staid by their voluptuousness. Settling in Rome, he became a journalist on the staff of the *Tribuna*, and in *Il Piacere* (1889) produced a notable novel, showing the influence of Maupassant and Bourget. *L'Innocente* (1891), translated into French, made him known abroad, and was followed by *Il Trionfo della Morte*, *Le Vergini delle Rocce*, and *Il Fuoco* (1900); *Il Poema Paradisiaco*, *Odi Navali*, and *Laudi*, in poetry; in drama, *Il Sogno* (1897), *Otta Morta*, *La Gioconda*, *La Gloria*, and *Francesca da Rimini*—the last hailed by the best Italian critics as one of the greatest of Italian dramas—*La Figlia di Iorio*, *Le Nave*. His creative gift is powerful but narrow; in grace and richness of style he outshines all Italian contemporaries. He urged Italy's participation in the Great War (of which he was official chronicler); and in 1919 led a private expedition which seized Fiume (until Dec. 1920), and later Zara, in defiance of Europe and America. He was created Prince of Montenevoso (1924).

**Dante Alighieri** (also written ALDIGHIERI, ALAGHIERI, and otherwise), 'that singular splendour of the Italian race,' as Boccaccio, his first biographer, calls him, was born in May 1265, the exact day being unknown. The house in which he was born is still shown in the Piazza di San Martino at Florence. His father was a lawyer, his mother, who was his father's second wife, was named Bella, but her surname is not known. The future poet was baptised with the Christian name of Durante, afterwards contracted into Dante, in the beautiful baptistry of Florence, towards which in his later years the tenderest thoughts of the hopeless exile turned (see *Inf.* xix. 17; *Par.* xxv. 1-12). The fancy of the old biographers loved to dwell on the appropriateness of both names, 'the much-enduring,' and 'the giver.' As with many other great men, a halo of legend surrounds the circumstances of his birth and early years. But the curtain is first lifted on his actual history, and that by himself, in his *Vita Nuova*, the New (i.e. probably Early) Life, when he relates how he first set eyes on 'the glorious lady of his heart, Beatrice,' he being then about nine years of age, and she a few months younger. To Boccaccio, and to his statement alone, we owe the generally accepted fact that she was the daughter of Folco Portinari, for Dante himself never gives the slightest clue as to her family name. Owing to his reticence on this point, combined with the extraordinary and, to modern notions, almost unintelligible amount of idealisation in Dante's language about her, some critics have (as might be expected) denied that she was a real person at all. That chance meeting in May 1274 determined the whole future course of the poet's life. The story of his boyish but unquenchable passion is told with exquisite pathos in the *Vita Nuova*. There is no evidence that any similar feeling was aroused in the heart of Beatrice Portinari. She was married at an early age to one Simone de' Bardi, but neither this nor the poet's own subsequent marriage interfered with his pure and Platonic devotion to her. This became even intensified after her death, which took place on June 9, 1290, when she was in her 24th year. Shortly after this Dante married Gemma Donati, a member of one of the most powerful families of the Guelph faction at Florence. According to Boccaccio, this marriage was recommended by his friends, alarmed at the condition of his health through overmuch sorrow. It has commonly been assumed that the marriage was an unhappy one. This, however, is merely a conjecture, supported mainly by the fact that after Dante's exile in 1301 he never appears to have seen, or cared to see, his wife again.

In 1289 Dante took part in the battle of Campaldino, in which the Florentines and their Guelphic allies defeated the Ghibelline league of Arezzo. The flight and death of Buonconte, who fought on the opposite side, is the subject of one of the most splendid episodes in the *Divina Commedia* (*Purg.* v.). Later in the same year he was present at the capitulation of Caprona, as he himself tells us in *Inf.* xxi. 94. With these experiences his military life seems to have closed. Soon after, we find him beginning to take part in politics, and according to the custom of the times, he first became registered in one of the city guilds—viz. that of the Apothecaries, he being then thirty years of age. It is interesting to note that he is there entered as 'Dante d'Alighieri, poeta.' It should, perhaps, have been mentioned that we know little of his early education, except that he is said to have studied at the then celebrated university of Bologna. According to some he was for a time a pupil of Brunetto Latini, of whom he speaks with the utmost veneration and affection, though a stern sense of justice compels him to place him in Hell (*Inf.* xv.). At the outset of his public life his sympathies were with the Guelph party, to which he would naturally have been attached by family ties both through his father and his wife. After filling minor public offices, and possibly going on some embassies abroad (though, doubtless, not all of those which later writers in their admiration have attributed to him), in the ever-memorable year 1300, the *mezzo cammino* of his own life, when he was thirty-five years old, the eve of a new century, the year of the first Jubilee at Rome, the assumed year of the great poetic vision of the *Commedia*, he attained to the dignity of one of the six priors of Florence. That singular office, lasting for only two months, seems (as Lowell suggests) to have been invented by the Florentines 'apparently to secure at least six constitutional chances of revolution in the year.' It should be explained that this was a very critical and stormy period at Florence. Not only was the eternal feud of Guelph and Ghibelline in full force, but a new excuse for party hatred had been found in the distinction of Black and White Guelphs, the latter being the more moderate party, who tended to verge towards the Ghibellines, and under certain circumstances to make common cause with them. So far as Dante could be called 'a party man' at all (see *Par.* vi. 100-3; xvii. 68-69), it was towards this section that his sympathies tended. His office as prior lasted from June 15 to August 15 in the year 1300. He distinguished his brief tenure of office by procuring the banishment of the heads and leaders of the rival factions by which Florence was torn asunder. He carried out this process with characteristic sternness and impartiality on Guelph and Ghibelline, White and Black alike, unmoved by any considerations of relationship, friendship, or political sympathy. Shortly afterwards the leaders of the Whites were permitted somehow to return. The partiality thus shown was a prominent feature in the accusation against Dante; but he had a complete answer in the fact that he was no longer in office at the time that it occurred.

In the following year, 1301, and probably in the autumn, in alarm at the threatened interference of Charles of Valois, who had now crossed the Alps, Dante was sent on an embassy to Rome to Pope Boniface VIII., under whose instigation Charles was acting. From that embassy he never returned, nor did he ever again set foot in his native city. For meanwhile had occurred the dreaded advent of Charles, nominally as peacemaker, on November 1, 1301. He espoused the side of the *Neri* or Blacks, and for three days the fight raged in the streets of Florence. Finally, the victory of the *Neri* was

complete, their opponents were slain or banished, and their houses sacked. Soon after, in January 1302, the sentence of banishment went forth against Dante and others, nominally on the charge, an utterly baseless one, of *baratteria*, or malversation in the office of prior in 1300. This was followed by a yet severer sentence on March 10, condemning them to be burned alive if ever caught, which was repeated again on September 2, 1311, and yet once more on November 6, 1315. We need not attempt here to follow the wanderings of his exile of twenty years. He made at first one or two hopeless attempts to return, but abandoned them, partly in disappointment at their failure, partly in disgust at the kind of associates with which such proceedings linked him (see *Par.* xvii. 61-69).

His principal halting-places seem to have been—first Verona, under the protection of one of the Della Scala family, described by him as 'gran Lombardo' with much eulogy in *Par.* xvii. 71. Then in succession he sojourned in Tuscany (with Count Salvatico), in the Lunigiano (with Moruello Malaspina), near Urbino (with Ugucione della Fagginola), and then at Verona again. During this period he is said to have visited Paris; but though there seems little doubt that he was actually there at some time of his life, yet some of his biographers connect this visit with the period of his early education. Among these is Serravalle, who wrote, it should be noted, as late as 1417, and who is also the sole authority for Dante's alleged visit to England and Oxford. Those who, like Boccaccio, take him to France during his exile, suppose him to have been recalled to Italy and politics by the election of Henry of Luxemburg as emperor, and his visit to Italy, where no emperor had set foot for more than fifty years (see *Purg.* vi. 105, &c.). The exile's hopes were now roused to the highest pitch, and he addressed an epistle to Henry, couched in language borrowed largely from Scripture, which to our ears sounds extravagant. His hopes were once more and finally crushed by Henry's unexpected death on August 24, 1313, after which Dante took refuge in Romagna, and finally in Ravenna, where for the most part he remained, under the protection of Guido Novello da Polenta, until his death. This took place on September 14, 1321. The precise cause of it is unknown. He was no doubt utterly broken in spirit and in health. He had been employed by his patron in an embassy to Venice, which proved unsuccessful, and he died very soon afterwards, as some biographers say, from grief and annoyance at his failure at Venice, and as others, with more probability, assert, from the effects of a fever, aggravated if not originally caused by the unhealthy marshes which he had traversed on his return to Ravenna by land, the Venetians having harshly refused to allow him to make the journey by sea.

He was buried with much pomp by his friend Guido at Ravenna, and there he still lies. At some unknown period, by unknown hands, and from a motive still unexplained, his body was removed from the sarcophagus in which it lay, and was walled up in the neighbouring church of St Francis, in a rough box, inscribed *Dantis Ossa*. There it was discovered by pure accident on May 27, 1865, and after the bones had been identified beyond possibility of doubt, they were replaced in the sarcophagus, from which it was found they had been abstracted. Dante had seven children, six sons and one daughter, Beatrice, who was a nun in a convent at Ravenna. His family, however, became extinct in the 16th century. His personal appearance is too well known to need much description. Fortunately, a cast was taken from his face after death, so that we have an absolutely

authentic record of his features. Boccaccio also, writing not very many years after his death, has preserved numerous personal details, such as that he was of moderate stature, stooping when he walked, slow and dignified both in gait and speech, reserved and taciturn in habit, but, when he spoke, keen, sarcastic, and often contemptuous. That he was devoted to music and painting appears from many passages in his works, as well as from current tradition.

The dates and sequence of his various works are a matter of conjecture, and are still very much disputed. Doubtless the *Vita Nuova* is the earliest. By far the most celebrated is the *Divina Commedia*, the pre-eminent greatness of which has tended to eclipse his other writings, which do not generally receive the attention they deserve. In this poem he purposes, and assuredly fulfils his purpose, 'to say of Beatrice that which never yet was said of any woman' (end of *Vita Nuova*). In this vision of Hell, Purgatory, and Heaven, we have, as it were, an encyclopedic view of the highest culture and knowledge of the age on philosophy, history, classical literature, physical science, morals, theology. All this, moreover, is expressed in the sublimest and most exquisite poetry, and with consummate power and beauty of language. The *Divina Commedia*, indeed, may be said to have made the Italian language, which was before so rude and unformed that Dante himself hesitated to employ it on such a theme, and is said to have commenced his poem in Latin. No work probably in the world, except the Bible and Shakespeare, has given rise to so large a literature. To say nothing of nearly six hundred MSS. in which it was copied before printing became common, there have been published hundreds of editions; it has been no less than a hundred times translated into various European languages; and of commentaries, introductions, essays, and monographs there is no end. About fifty years after Dante's death, a public lectureship on the *Divina Commedia* was established at Florence, to which Boccaccio was first appointed.

The next most important work (and one throwing much light on the *Commedia*) is the fragment called the *Convivio* or *Convito*. It takes the form of a commentary on some *canzoni*, or short poems, of the author, of which there are only three, though the work, if completed, would have contained fourteen of these 'courses,' as the author calls them. Its contents are almost as encyclopedic as those of the *Commedia*. The *De Monarchia* (written in Latin) expounds Dante's theory of the right, and, as he held, divinely-intended, government of the world, by a universal emperor acting in harmony with a universal pope, respectively administering, without conflict or interference, the temporal and spiritual affairs of mankind. Another work, again unfinished, since it consists of two books only, when four were promised, is the *De Vulgari Eloquentia*. It also is written in Latin, and is a discussion of the origin of language, the several divisions of languages, and the numerous dialects of Italian in particular. A considerable collection of short poems, *canzoni*, sonnets, &c., is also preserved under the title of the *Canzoniere*, and finally, we have about a dozen epistles addressed mainly to leading statesmen or rulers, and dealing with the most urgent political problems of the day. There are also some *Eclogues* and other minor works, as well as several of doubtful authenticity which are sometimes assigned to him.

Of editions of the *Commedia*, Brunone Bianchi and Fraticelli are the most serviceable for ordinary students; for more thorough and critical studies, Scartazzini (3 vols.) and Mario Casella; for the *De Monarchia* and the *Vita Nuova*, also the *Commedia*, Witte; for all the works,

Fraticelli, Barbera (Florence, 1921), and the Società Dantesca Italiana; for all except the *Commedia*, Giuliani. The *Oxford Dante*, a complete text (3 vols.), was published in 1894 (4th ed. rev. by Paget Toynbee, 1924) by Dr E. Moore, who wrote *Dante and his Early Biographers* (1890). On Scartazzini's *Prolegomeni della Divina Commedia* (1890) is based the German *Dante Handbuch*, translated by Butler (1894) as *A Companion to Dante*. The invaluable *Bibliografia Dantesca* of Colomb de Batines was continued by Carpellini (1845-65) and by Petzholdt (1865-80). L. G. Blanc's *Vocabolario Dantesco* is very valuable; and Paget Toynbee's *Dictionary of Proper Names, &c., in Dante* (1898). See books by Miss M. F. Rossetti (1871), Butler (1895), Paget Toynbee (1900), Church (1888); Vernon's *Readings* (1906-9); Croce, *La Poesia di Dante* (1920). The principal English translations in verse are by Cary, Wright, Cayley, Pollock, Longfellow, Plumptre, Haselfoot, Shadwell, Langdon, Rossetti, Sibbald, and Musgrave (the last three the *Inferno* only); and in prose by Dr John Carlyle (*Inferno* only), Butler, and Norton.

**Danton**, GEORGES-JACQUES, was born of good farmer-people, at Arcis-sur-Aube, 26th October 1759. The outbreak of the French Revolution found him a quiet and studious man, practising as an advocate in Paris, but ere long its fever filled his veins. It was not till 1792, however, that he became a great leader, as we find no trace of his influence in such movements as the destruction of the Bastille and the forcible removal of the court from Versailles to the Tuileries. Mirabeau quickly detected Danton's genius, and hastened to attach him to himself, but his death in the spring of 1791 removed the last stay to the speedy downfall of the monarchy and the onward progress of a turbulent and infatuated democracy. Along with Marat and Camille Desmoulins, Danton instituted the Cordeliers' Club, which soon became the rallying-point of all the hotter revolutionists. There the tall brawny man—a born Tribune—with harsh and daring countenance, beetling black brows, and a voice of enormous power, thundered with vehement eloquence against the aristocrats, till the passions of the populace rose into ungovernable fury. Meantime the unhappy king stumbled into ever new blunders—most fatal, the attempt to flee from Paris (June 1791), and the affair of the Champ de Mars (July 2, 1791). Assertions have been made that Danton was after these events corrupted by the court, but there is no trustworthy evidence of this, and it is certain that his hostility to the monarchy remained as implacable as ever. 'The Mirabeau of the Sansculottes' was, indeed, says M. Claretie, 'a kind of bourgeois Mirabeau, equally powerful, but neither dissolute nor venal.' Danton's share in the insurrectionary march on the Tuileries (10th August 1792) is very doubtful, but it is certain that immediately thereafter he appears as Minister of Justice. And now the gigantic personality of the man seemed to overshadow all the surrounding figures. He stood forth as the incarnate spirit of the Revolution, manifesting alike its heroic audacity in the presence of danger from without, and its mad suspicion and terror of danger from within. The advance of the Prussians seemed for a moment to strike a panic to the heart of France. On the 2d of September Danton mounted the tribune, and addressed the Legislative Assembly in a speech of tremendous power, which closed with the famous words regarding the enemies of France: 'Pour les vaincre, pour les atterrir, que faut-il? De l'audace, encore de l'audace, et toujours de l'audace.' The heart of Paris was moved with resistless enthusiasm: she poured forth army after army of her sons, whose fiery valour quickly drove the invaders from the sacred soil of France. But the excitement of Paris was not all heroic—the September murders in the prisons were merely an outburst of cowardice and fear. Danton had perhaps no share

in this atrocity, for which Marat was mainly responsible, but he admitted that such excesses were incidental to a revolution, and condoned them as merely morbid and passing ebullitions of forces that would yet flow freely in healthy channels.

Danton voted for the death of the king (January 1793), was one of the nine original members of the Committee of Public Safety, and frequently went on missions to Dumouriez and other republican generals. In the Convention he now bent all his giant strength to crush the Girondists, or moderate party, on whose fall the extremists found themselves supreme. But he could not restrain the forces he had created, and his heart filled with ineffectual pity when the heads of opponents against whom he had thundered in debate fell under the merciless guillotine of the triumphant Mountain (October 1793). Danton was chiefly instrumental in setting up a strong central authority within the Committee of Public Safety and investing it with dictatorial powers, but he elected not to belong to it himself. Henceforth all his energies were devoted at once to fire the hearts of Frenchmen against the foreign enemy, and to conciliate domestic hatreds. He strove with all his might to abate the fanatical and pitiless severity of the revolutionary tribunal, but although Hébert and his party were cut off, Danton's policy of clemency failed to commend itself to the Mountain, whose ferocious instincts saw a more promising leader in the narrow and acrid Robespierre. A fruitless attempt was made to reconcile the two, but their interview left them worse friends than before. Meantime Danton was strangely careless of his fate. He went awhile for rest to his native Arcis, and forgot all the machinations of his enemies in the quiet of domestic happiness with the wife he had just married. 'I prefer being guillotined to guillotining,' he said to a friend—a great saying which history will remember. Soon his friends summoned him to return to Paris. When news was brought him that the warrant for his arrest was made out, he said merely, 'They dare not,' and calmly went to sleep as usual. Arrested at last, he carried his head high until his doom:—'I leave the whole business in a frightful welter. Not one of them understands anything of government. Robespierre will follow me; I drag down Robespierre. Oh, it were better to be a poor fisherman than to meddle with governing of men.'

On the 2d April 1794 he was brought with Camille Desmoulins and a group of his friends before the bar of the Revolutionary Tribunal he had formed a twelvemonth before. Asked his name formally by Fouquier-Tinville, the attorney-general, he replied with more than his customary greatness of phrase: 'My name is Danton: a name tolerably known in the Revolution; my abode will soon be annihilation; but I shall live in the Pantheon of history.' His defence was sublime in its audacity, its incoherence, its mixture of heroism and magnificent buffoonery. 'I sold to the enemy!' he exclaimed, 'A man of my stamp is priceless.' 'Do I look like a hypocrite?' was his only answer to one of the absurdest of the charges. The first two days of his trial his mighty voice and passionate eloquence moved the people so greatly that the Committee of Public Safety in terror hastily concocted a decree that the mouths of men who had 'insulted Justice' should be shut; and only with this shameful outrage upon justice were his enemies able to send to his doom the greatest figure that fell in the Revolution (April 5, 1794). At the foot of the scaffold the thought of his much-loved wife filled his heart, but with the words, 'Danton, no weakness,' he nerved his heart to die as he had lived. To the headsmen he said, 'Thou wilt show my head to the people; it is worth showing.'

The outlines of the Titan of the Revolution in Carlyle's glowing pages are none too heroic; his story is written large on the annals of his time.

**Dantsic.** See DANZIG.

**Danube** (Lat. *Danubius*; in the lower course, *Ister*; Ger. *Donau*; Hung. *Duna*; Slav. *Dunaj*), the second river of Europe, inferior only to the Volga, has its origin in the Brege and Bigach, two mountain-streams issuing in the Black Forest, in Baden, and uniting at Donaueschingen, 2264 feet above sea-level. The Danube has a total length, including windings, of 1740 miles, and drains an area estimated at 300,000 sq. m. It flows first SE. to Gutmadingen, and then NE. to Ulm (1519 feet above sea-level), which may be taken as the limit of its upper course. A few miles above Ulm it receives on its right bank the Iller, from which point it is navigable for boats of 100 tons. At Regensburg (Ratisbon) the river reaches its most northerly point (49° 2'), and from thence its course is generally SE. to the northern frontier of Bulgaria. Between Ulm and Passau, where it enters Upper Austria, it receives, among other tributaries, the three large alpine streams, the Lech, Isar, and Inn, on the right, and the Altmühl and Regen on the left bank. At Passau its width is 231 yards, and its depth 16 feet. The crystalline rocks of the Bohemian Forest mountains follow the stream into Austria, and as far as Aschach its banks are wild and picturesque. It flows E. to Presburg with little variation of course, receiving the Ens from the S., and the March or Morava from the N.; and passing through an opening, called the Carpathian Gate, between the Leitha chain and the Lesser Carpathians, where its width is 320 yards, and its depth 20 feet, it separates Hungary from Czechoslovakia. Between Presburg and Komorn the stream divides, and forms the Great and Little Schutten, or alluvial islands. Near Waitzen it turns directly S., and enters upon the Hungarian plain, a vast sandy alluvial flat, in which it is continually forcing new channels and silting up old ones; it maintains this course for 230 miles, receiving from the N. the Waag and the Gran. Lower, in Yugoslav territory, the Drave from the W. adds considerably to its volume.

After this last accession, the Danube turns again SE., and, increased by the waters of the Theiss from the N., sweeps past Belgrade, where it is joined by the Save, and lower by the Temes. At Semlin, near Belgrade, it is 1706 yards wide and 46 feet deep, but the width is greatly contracted by spurs of the Transylvanian and the Serbian mountains for 75 miles below the plains of the Vojvodina. Within this stretch are eight distinct rapids, shut in by lofty walls, and strewn with rocky shoals of limestone, crystalline schists, and granite. The lower Klissura is the most strikingly picturesque of these, but the most difficult passage is the shortest (1½ mile) of the eight—the 'Iron Gate,' properly so called, below Orsova, where the middle course of the river ends. Here the stream has a breadth of only 129 yards, and the piled-up waters attain a depth of 28 fathoms; ledges of rock lift their tooth-like points above the surface, and all around a seething stretch of whirlpools, cataracts, eddies and counter-eddies, combines with the river's rapid fall to present a serious and formerly impassable obstacle to navigation. Many attempts have been made to improve the bed here, which, under article 57 of the Berlin Treaty of 13th July 1878, Austria bound herself to clear. The mandate was later transferred by Austria to Hungary, and was abrogated by the peace treaties of 1919. From here the Danube enters on the Wallachian depression, and flows in a wide stream, through a district

fertile, indeed, but solitary and poorly cultivated, constantly broadening into a lake, or overspreading its banks with swamps. It drains the country between the Transylvanian mountains and the Balkans, forming the northern boundary of Bulgaria, and running into south-eastern Rumania, past Silistria. Lower it turns northward, skirting the Dobruja, and flows between marshy banks to Galatz, receiving on the way the Jalomitza and the Sereth. From Galatz it flows E., and, after being joined by the Pruth from the N., SE. to the Black Sea. The delta, which begins 5 miles W. of Tulja, is a vast wilderness, covering an area of 1000 sq. m., and resembling an immense green sea of rushes; it is cut up by numerous channels and lakes, and is the haunt of sea-birds, wolves, and buffaloes. The farthest mouths are 60 miles apart. Two-thirds of the Danube's volume passes through the Kilia, but this arm forms a secondary delta near its outlet, and the southern or St George branch also forms two channels; it is consequently by the middle or Sulina mouth that ships enter, although it discharges only 9 per cent. of the river's waters. The improvements (since 1858) of this mouth have increased the depth over the bar from 7 or 11 feet (according to the season) to a minimum depth of 23 feet. And cuttings have shortened the course of the Sulina branch by eleven nautical miles. To defend Vienna against risk of inundation, the course of the Danube skirting it was, in 1868-81, diverted into an artificial channel, and the bed has since been improved, above and below the city, from the mouth of the Isper to that of the March. Similar works have been carried out near Budapest, and a new channel, cut at vast expense, to avoid the impediments to navigation at the Iron Gate, was opened in 1896. Until then any effectual improvements of that passage had never advanced beyond the stage of projects, while throughout Hungary and along the lower course inundations had caused great damage. The operations were actually begun by the Hungarian government in 1890. A great steel cantilever railway bridge across the Danube at Tchernavoda in Rumania (with its approaches, 11,800 yards long) was opened in 1895. It partly rests on the island of Balta. The Danube has about 400 tributaries, 100 of them navigable. Nevertheless, owing to the obstructions and to the shifting course of the stream, the tonnage of the Danube trade is inferior to that of the Elbe. The Danube is connected with the Rhine by means of the Ludwigs Canal (1844), and other canals connecting with the Rhine, Elbe, Oder, Vistula, and Dniester are projected.

The International Danube Navigation Commission was constituted in 1856, when at the Peace of Paris the navigation of the river was declared free to all nations, and was composed of delegates of all the great powers, to whom a representative of Rumania was added from 1878. It was appointed on the express condition that it should dissolve in 1858, but such was its usefulness that it was informally continued till 1866, when the Conference of Paris formally prolonged its powers for five years. In 1871 the Conference of London continued the Commission for twelve years, and in 1883 a second London conference continued it to 1904, and thereafter until denounced. It was revived, with temporary modifications, after the Great War. It exercises almost sovereign power on the mouths of the Danube, where it has conducted the great engineering works already referred to; it has its own flag, uniform, and revenue, and has raised loans, made laws, and maintained its own small army of police. Its jurisdiction, originally limited to the river between Isakcha and the sea, was extended at the Congress of Berlin (1878) as far as Galatz, and after-

wards to the Iron Gate, and later restricted to the portion from Braila to the Sulina mouth. It has its headquarters at Galatz. Its revenue is derived from a tax upon ships leaving the river. The peace treaties of 1919-20 set up another International Commission for the remainder of the Danube, up to Ulm.

**Danubian Principalities**, a name applied to Moldavia and Wallachia. See RUMANIA.

**Danvers**, a town of Essex county, Massachusetts, 4 miles NW. of Salem, with manufactures of shoes, carpets, bricks, &c. It is the seat of the state asylum for the insane. Pop. 11,000. Peabody, 3 miles to the south, was formerly South Danvers.

**Danville**, (1) capital of Vermilion county, Illinois, on the Vermilion River, 124 miles S. of Chicago. It is an important railway junction, and contains railway-shops, besides a number of flour and lumber mills, foundries, &c. Bituminous coal is mined near by. Pop. 34,000.—(2) Capital of Montour county, Pennsylvania, on the north branch of the Susquehanna, 62 miles N. by E. of Harrisburg. The place was first settled in 1768, and the Pennsylvania Ironworks here is the oldest establishment in the United States for the manufacture of railroad iron. There are also numerous blast-furnaces, foundries, and rolling-mills. Pop. 7000.—(3) A flourishing city of Virginia, on both sides of the Dan River, here spanned by an iron bridge, 126 miles SW. of Richmond, with large cotton and other mills, and a very important trade in tobacco. Pop. 21,500.

**D'Anville**, JEAN BAPTISTE BOURGUIGNON, a geographer and map-maker, was born at Paris, 11th July 1697, and devoted himself to mathematical and geographical studies with such zeal and success that in 1719 he was appointed geographer to the king. He died 28th January 1782. He published in all 211 maps; the most notable collections were the *Atlas Général* (1737-80), and the *Atlas Antiquus Major*, with its accompanying three volumes of *Géographie Ancienne* (1769).

**Danzig** (Polish *Gdańsk*), an important seaport, till 1919 capital of West Prussia, now politically a free city (German in population), on the left bank of the western branch of the Vistula, 284 miles NE. of Berlin by rail, and about 4 miles from the river's mouth in the shallow Gulf of Danzig, an inlet of the Baltic. Danzig was an important town in the 10th century, and its possession was contended for by Danes, Pomeranians, Prussians, Brandenburgers, Poles, and the Teutonic Knights, the last of whom held it from 1308 to 1454, when it became a free city under Poland. In 1793 it fell to Prussia, in whose hands, except during the years 1807-14, when it existed as a separate dukedom under Napoleonic rule, it continued till 1919. The Treaty of Versailles separated Danzig, with a small area around it (709 sq. m.; pop. in 1919, 356,740), from Prussia and the German empire, making it a free city under the League of Nations, to be included in the Polish customs area, Poland having rights in the port and control of foreign relations. The town is protected by a wall with twenty bastions, and by wet ditches, and possesses works for laying the surrounding country under water on three sides; its works are strengthened by outlying forts, and a chain of batteries extends to the mouth of the river. The city is traversed by the Mottlau and Radanne, tributaries of the Vistula, the former of which has been deepened and admits vessels up to the *Speicherinsel*, an island forming one of the quarters of the town, retained for the storage of grain. The principal port is Neufahrwasser, at the mouth of the Vistula, below the sand-bars. Many of the streets of Danzig are

narrow and crooked, but the *Langgasse*, intersecting it from east to west, presents a most picturesque appearance, with its lofty gable houses of the 16th and 17th centuries; and there are good suburbs to the west, with wide thoroughfares. Among the most noteworthy buildings are the large church of St Mary (1343-1502), with a noble 'Last Judgment,' painted probably by Memline, and a finely carved altar of wood; the church of St Catharine (1326-30); the fine old Gothic town-hall; the old exchange; and the Franciscan monastery, now used as a museum and art gallery. Danzig was at one time a prominent member of the Hanseatic League, and is still one of the chief commercial cities of northern Europe. Its seaward imports are chiefly herrings, cotton, iron, drugs, coal, coffee, and hides; its exports, sugar, wheat, timber, spirits, &c. The river and railway trade is also important. The manufactures include beer, spirits (Danzig *Goldwasser*), sugar, tobacco, flour, iron-wares, machinery, amber, gold and silver ornaments; and ships are built. The town has a large library, and is well supplied with hospitals, asylums, schools, museums, &c. Oliva Abbey (c. 1200) is the cathedral of the Roman Catholic diocese of Danzig. Pop. (1880) 108,551; (1900) 140,539; (1910) 170,337; (1919) 194,953.

**Daoudnagar.** See DAUDNAGAR.

**Daphne**, a nymph who, chased by Apollo, changed herself into a laurel. The myth is a *point d'appui* of the solar mythologists. Daphne was the name of a famous grove of cypresses and laurels near Antioch, with a temple of Apollo.

**Daphne**, a genus of Thymelaeaceæ, all shrubs or small trees, deciduous or evergreen, acrid and with poisonous berries, but often with deliciously fragrant flowers. The deciduous *Mezereum* (*D. Mezereum*), well known both for the fragrance of its pink winter flowers and for its medicinal uses, is naturalised in some places of England. The only species certainly a native of England is the Spurge Laurel (*D. Laureola*), an evergreen shrub, 3 to 4 feet high, with large, leathery, tufted leaves,

Daphne Cneorum.

and greenish-yellow axillary flowers. It grows well under the shade of trees, and flowers in February, while the nearly allied *D. pontica*, introduced from Asia Minor, flowers a month later. Upon the three species are grafted the rarer or less hardy species. Easily recognised by its trailing and branching habit, with persistent smooth, linear, obtuse, mucronate (box-tipped) leaves, and its fragrant profusion of terminal flowers in early spring, *D. Cneorum* is the best of all species for small gardens; while *D. alpina*, with its varieties *Dauphin* and *Verloti*, is a pretty deciduous form for rock-work.—*D. japonica*, from Japan, has lemon-scented leaves. From the bast of some species of Daphne, and nearly allied genera, useful fibre is obtained, and paper is made in different parts of the East, particularly *Nepal* paper from that of *D. cannabina*. In Tibet *Edgworthia Gardneri* is employed in the same way.

**Daphnia.** See WATER-FLEA.

**Dapsang**, highest peak (28,700 feet) of the Karakorum (q.v.).

**Darabgherd**, or DARAB, a town of Persia, in Farsistan, 115 miles SE. of Shiraz; pop. 4000.

**Daraganj**, a suburb of Allahabad, stands 2 miles distant, on the right bank of the Ganges.

**Darbhangha**, the chief town of Darbhanga district, in Bihar and Orissa, on the little Bagmati River, 78 miles NE. of Patna by rail. It has large bazaars and a handsome market-place, extensive tanks, a hospital, and the maharaja's palace, with fine gardens, menagerie, and aviary. There is an active trade in oil-seeds, food-grains, timber, salt, iron, lime, &c. Population, 63,000.—The district has an area of 3348 sq. m., forming one large alluvial plain, intersected by a network of streams, and covered with wide rice-fields, bamboo, and mango-groves. The rivers flood extensive areas, and fever is endemic. Rice, indigo, linseed, mustard, and tobacco are the chief crops; the manufactures include indigo, sugar, saltpetre, pottery, cloth, and tobacco. Pop. 3,000,000.

**D'Arblay**, MADAME, better known as a novelist by her maiden name of Frances Burney, was born at King's Lynn, 13th June 1752, the second daughter and the third child of the six children of Dr Burney, then organist there. Her father removed to London to teach music in 1760, and on his wife's death next year sent his daughters Esther and Susannah to a school in Paris, but kept Fanny at home from a fear that her great affection for her maternal grandmother, then in France, should make her a convert to Catholicism. Dr Burney's second marriage in 1766 gave her a kind step-mother, but did not end her day-dreams nor her incessant scribbling of stories, plays, and poems, begun at ten, although but two years before she was ignorant of her letters. On her fifteenth birthday, in a fit of repentance for such waste of time, she burned all her papers, but she could not erase from her brain the plot of the story which grew later into *Evelina*, or *a Young Lady's Entrance into the World*. This was sold for £20 to Lowndes, and published anonymously in January 1778, not even her father having seen the manuscript, although he had been dutifully told beforehand of the project. Dr Burney at once recognised his daughter's touch, and soon confided the secret to Mrs Thrale, who, as well as Dr Johnson, petted and flattered the gifted young authoress to her heart's delight. The praises showered upon the book by Johnson, Reynolds, Burke, and the whole world of fashion, might well have turned her head, and are told in delightful detail in her diary. Urged to write a comedy, she had the sense to suppress it in deference to the criticisms of her father and Samuel Crisp, a sagacious old critic, soured to the world but not to her, the 'daddy' of so many of her letters. In 1782 she published *Cecilia*, which was no less successful than her first novel. At Windsor, in the house of her friend the venerable Mrs Delany, she became known to the royal family, and soon received (July 1786) the appointment of second keeper of the robes at court, with a salary of £200 a year. She soon found her menial duties intolerably tedious, and her health began to decline, but her veneration for the queen kept her from resigning until compelled by the remonstrances of Burke, Boswell, Windham, and others of her father's friends. At length in July 1791 she was permitted to retire with a pension of £100 a year, and soon recovered her health and spirits by travelling in England. At Norbury Park, near Dorking, she met General D'Arblay, a French refugee, and married him on nothing more than her pension in July 1793. Her third novel, *Camilla*, was published by subscription in 1796, and brought her, it is supposed, about 3000 guineas, with which she built Camilla Cottage, near Mickleham. It was, however, nothing more than a pecuniary success, while her tragedy, *Edwy and Elvina*, had already been damned in 1795, spite of the acting of Mrs Siddons and Kemble. From 1802 to 1812 she lived at Passy in France with her husband, who

had procured civil employment there, then returned to England with her son, tended her father till his death in April 1814, and in the beginning of the same year published her last novel, *The Wanderer*, another literary failure. At the first Restoration she joined her husband in Paris, was at Brussels during the battle of Waterloo, and soon after returned finally to England with her husband, who died 3d May 1818. Her son was tenth wrangler at Cambridge that year, took orders, became minister at Ely chapel in 1836, and died of decline in 1837. In 1832 Madame d'Ablay published her memoirs of her father, written in a pretentious style, and died 6th Jan. 1840. Five volumes of her *Letters and Diaries* were published in 1842, two more volumes in 1846, and the *Early Diary* in 1890. Spite of its tedious triviality this work is invaluable from the insight it gives us into the very heart of the dull decorous court of George III., and much more from its revelation of English manners towards the end of the eighteenth century. Its stories of Dr Johnson and his group will live in literary history. Croker's ill-tempered attacks on her veracity for allowing an impression to go abroad that *Evelina* had been written at seventeen, printed in the *Quarterly Review* for April 1833 and June 1842, were satisfactorily answered by Macaulay in the *Edinburgh Review* for January 1843. As a novelist, Frances Burney's greatest merit is that she conceived the idea of representing modern society in a manner realistic without ceasing to be feminine and completely artistic. She was the forerunner of Miss Edgeworth and Jane Austen.

See Austin Dobson's *Fanny Burney* (1903), and his four-volume edition (1904-5) of her letters; also Frankfort Moore, *The Keeper of the Robes* (1911).

**Darboy**, GEORGES, an ill-fated Archbishop of Paris, was born 16th January 1813 at Fayl-Billot, in Haute-Marne. He was educated at the seminary of Langres, and four years after his ordination as priest (1836) was appointed a professor there. In 1845 he came to Paris, where his reputation as translator of Dionysius the Areopagite had preceded him. In 1854 he was made protonotary apostolic, in 1859 Bishop of Nancy, and in 1863 Archbishop of Paris. He strenuously upheld the Gallican theory of episcopal independence, and waged a long struggle with the Jesuits that lost him the favour of the holy see. At the Vatican Council he opposed with vigour the declaration of the papal infallibility, but when the dogma was finally adopted, was one of the first to set the example of submission. During the German siege of Paris he was unceasing in labours of benevolence, and during the brief but dreadful triumph of the Commune he refused to leave his flock. Arrested as a hostage by the Communards, 4th April 1871, he was shot in the court of the prison of La Roquette on the 24th of May. He died with the heroic courage of the Christian martyr, words of forgiveness on his lips, and his hands lifted in blessing as he fell. His two immediate predecessors had likewise died a bloody death—Sibour murdered during the celebration of a religious rite (January 3, 1857); Affre shot down on the barricades (June 1848). Darboy's body was reinterred in a stately public funeral, 5th June 1871. See Lives by Foulon (1889) and Price (1915).

**Darbyites**, a name often applied to the Plymouth Brethren (q.v.) from their principal founder, John Nelson Darby (1800-82), of whose collected writings thirty-two volumes have appeared (1867-83). See his *Personal Recollections* (1881).

**D'Arc**. See JOAN OF ARC.

**Dardanelles**, or HELLESPONT, a narrow channel separating Europe from Asia, and uniting the Sea of Marmora with the Archipelago. The name

is derived from the ancient city of Dardanus in the Troad, on the southern shore; and Dardanus was named from the Dardani, an ancient people farther inland. See DARDANUS. The strait extends from north-east to south-west, and has a length of about 40 miles, and a breadth varying from 1 to 4 miles. From the Sea of Marmora a strong current runs through the strait to the Archipelago. Both sides were strongly fortified till 1920. A treaty concluded between the five great powers and Turkey in 1841 arranged that no warship should pass without Turkey's consent, all merchant-ships being also required to show their papers. These provisions were confirmed at London in 1871 and at Berlin in 1878, in which year a British fleet had sailed into the Sea of Marmora. The Dardanelles is celebrated on account of Xerxes and Alexander having crossed, the former in 480 B.C. to enter Europe, and the latter in 334 B.C. to enter Asia. The point at which Xerxes crossed, by two bridges, was near Abydos, on the Asiatic shore, opposite to Sestos. Alexander crossed at nearly the same place; and here also young Leander nightly swam across to visit Hero—a feat performed in 1810 by Lord Byron. In the Dardanelles Lysander defeated Conon (at Ægospotami) in 405 B.C., and Adelaar (q.v.) the Turks in 1654. Admiral Duckworth got through in 1807, but the British and French failed in 1915. See WAR (GREAT). The treaty of Lausanne (1923) provided for the freedom of the straits in time of peace, and for neutrals when Turkey is at war.

**Dardanus**, a son of Zeus and Electra, daughter of Atlas, the mythical ancestor of the Trojans and Romans. Originally a king in Arcadia, he migrated to Samothrace, thence to Asia, where King Teucer gave him the site of his town, Dardania or Dardanus. He married a daughter of Teucer, and his grandson was the eponymous hero Tros, who removed his grandfather's Palladium to Troy.

**Dardistan**, a region of the North-west Frontier Province and Kashmir, consists of lofty mountains and high-lying valleys. It is little known, and its limits are variously given. But its interest depends mainly on the fact that its inhabitants, the Dards, are an Aryan people, speaking a Sanskritic tongue mixed with Persian words. They had been called 'Stray Aryans in Tibet,' and are Moslems converted from Buddhism at a comparatively recent period: the raja of Kashmir is constantly endeavouring to subject them completely to his authority. The chief districts are Hasora, Gilgit, and Tassin; some would also include Chitral (q.v.) in Dardistan. See Leitner's *Tour in Dardistan* (1867-70), and KASHMIR.

**Dar-es-salaam**, a seaport of Tanganyika Territory (q.v.), 45 miles S. of Zanzibar; pop. 25,000.

**Dares the Phrygian**. See TROY.

**Dar-fertit** is the name of the thinly peopled territory south of Dar-Fûr, beyond the Bahr-el-Arab, and north of the Niam-Niam country.

**Dar-Fûr**, a country of Central Africa, one of the divisions of the Sūdān or 'Land of the Blacks,' situated approximately in 10° to 16° N. lat., and in 22° to 28° E. long.; but its limits are not clearly defined. It is hilly in parts, and traversed by a mountainous ridge called Marra, which is the source of numerous streams. Towards the north it is level, sandy, and almost destitute of water. During the rainy season (June—September) it exhibits a rich vegetation. The principal products are wheat, millet, rice, maize, and sesame. Tobacco, which is used by the natives in every form, abounds. Water-melons, also, are abundant during the rainy season. Among the fruits are tamarinds and dates. The chief minerals are copper and iron. The wealth of the inhabitants consists principally in cattle. Horses, sheep, camels,

ostriches, and game abound. The 3,000,000 or so of inhabitants are mainly Fulahs (q.v.). Dar-Für, long a centre of the slave-trade, was annexed to Egypt in 1874-75, but suffered with the rest of the Sudan from the desolating tyranny of the Mahdi (q.v.) and his successor the Khalifa, till the defeat of the latter in 1898. It is part of Anglo-Egyptian Sudan. The sultan took up arms in 1916, but Col. Kelly occupied his capital, El Fasher. See EGYPT, SUDAN.

**Dargai**, a plateau in the Afridi country on the NW. Indian frontier, taken in a fight in which Gurmhas and Gordon Highlanders specially distinguished themselves, 21st October 1897.

**Dargan**, WILLIAM, railway projector, born in County Carlow, 28th February 1799, spent some time in a surveyor's office, and for a time was employed under Telford. He was a successful contractor, and became one of the first capitalists in Ireland. It was he who in 1831 contracted for the first railway ever executed in Ireland (the Dublin and Kingstown), and he was afterwards connected with most great Irish undertakings, such as the making of railways, canals, tunnels, and embankments. He was also an extensive holder of railway stock, a steamboat proprietor, flax-grower, farmer, and the main promoter of the Dublin exhibition of 1853, when he declined a baronetcy. He died 7th February 1867.

**D'Argens**, JEAN BAPTISTE DE BOYER, MARQUIS, born at Aix, in Provence, 1704, at the age of fifteen entered the army, but disabled in 1734 by a fall from his horse, and disinherited for his follies, he went to Holland and tried his fortune in authorship. Frederick the Great, then crown prince of Prussia, was attracted by his writings, and on his accession invited him to the court of Prussia. The king appointed him chamberlain and a director of the fine arts. When almost a sexagenarian he renewed the adventures of his youth by again falling a victim to the charms of an actress, whom he married without Frederick's permission. Deprived of his pension, he returned to Provence, and died near Toulon, 1771. His works fill 38 volumes. See his *Mémoires* (new ed. Paris, 1807).

**D'Argenson**, MARC PIERRE, COMTE, a celebrated French statesman, was born in 1696, the younger son of the Marquis d'Argenson (1652-1721) who created the secret police and established the *lettres de cachet*. After holding a number of inferior offices, he became war minister in 1743, at a time when the very political existence of France was imperilled, and by his vigour and lucky choice of generals changed the fortunes of the war in the course of a single year. After the peace of Aix-la-Chapelle (1748), he devoted himself to the improvement of the military system, and in 1751 established the École Militaire. He was an illustrious patron of literature. Diderot and D'Alembert dedicated to him their great *Encyclopédie*; and to Voltaire, whose fellow-student he had been, he furnished materials for his *Siècle de Louis XIV.* In 1757 he was banished to his estate by the machinations of Madame Pompadour; but on her death he returned to Paris, where he died in 1764.

**Daric**, a Persian gold coin named after Darius, weighing rather more than a sovereign.

**Dariel**. See CAUCASUS.

**Darien**, a name formerly applied to the entire isthmus now generally known as Panamá (q.v.). It is now more properly confined to the heavily-wooded hill-country lying between the Gulfs of Uraba on the north and San Miguel on the south. The former, a principal inlet of the Caribbean Sea, is commonly called the Gulf of Darien; and the inhabitants distinguish San Miguel as the Darien of the South. The southern extremity of the

northern gulf forms the Bay of Choco, into which the river Atrato (q.v.) debouches; the southern gulf receives the Tuira, after a course of 190 miles, of which over 100 are navigable. Little of the district, which is rich in gold, has yet been explored. There is, however, an active trade in tortoiseshell, pearls, and gold-dust, which the Indians readily barter for firearms and rum. These natives are said to number 20,000, are uncivilised, and as expert with the gun as were their ancestors with the bow. The capital of the district is Yaviza.

**Darien Scheme**, a disastrous speculation projected by William Paterson (q.v.), the founder of the Bank of England, was established by act of the Scottish parliament, and was sanctioned by royal authority in 1695. Its object was to plant a colony on the Atlantic side of the Isthmus of Panamá, and so form a commercial entrepôt between the eastern and western hemispheres. An entire monopoly of the trade of Asia, Africa, and America, for a term of thirty-one years, was granted to the Company. At that time, the foreign trade of Scotland had been ruined by the English Navigation Act of 1660, which provided that all trade with the English colonies should be conducted in English ships alone, so that when Paterson opened his subscription-list, the nobility, the gentry, the merchants, and people, royal burghs, and public bodies in Scotland all hastened to subscribe. No less than £400,000 was immediately put down on paper, of which £220,000 was actually paid up. Deputies in England received subscriptions to the amount of £300,000; and the Dutch and Hamburgers subscribed £200,000. The English parliament, however, actuated by a feeling of national antipathy, and the jealous clamours of trading corporations, gave its unequivocal condemnation to the scheme. The British resident at Hamburg, probably with the concurrence of William III., also made various insinuations against it. The result of this interference was the almost total withdrawal of the Dutch and English subscriptions. It must now be admitted that there was one fatal objection to the scheme—viz. the danger of settling on ground claimed by Spain, without coming to a proper understanding with that country beforehand. Unable, however, to see any sort of obstacles, incited by the vehement eloquence of Paterson, and dazzled by the magnificent proportions of the scheme, the Scotch hurried forward their arrangements. Five ships, with 1200 men on board, set sail from Leith for Panamá on the 25th July 1698. They reached their destination in four months, near what is still called Puerto Escoces (in 8° 50' N. lat.), and having bargained with the natives for a country which they called New Caledonia, the colonists fixed the site of what was to be their capital, New Edinburgh, and built a fort in its vicinity, which they named New St Andrews. Having thus constituted their colony, they issued a proclamation of perfect freedom of trade and universal toleration in religious matters to all who should join them. For the first few months they seemed to be on the highway to success. But the climate, which was tolerable in winter, became unbearable in summer, and many sickened under it; their supplies failed before they could derive a return from the soil; and on sending to the British colonies in America for provisions, they learned with the deepest indignation and despair that the British American colonies, having been informed that King William had not given his sanction to the expedition, had resolved to hold no intercourse with the new colony at Panamá.

Sickly and desponding, they waited long for supplies from the mother-country; but the Company at home was not aware of their wretched

condition, and none came. At length, having waited eight months for assistance, the colony broke up. In the meantime, 1300 colonists had set sail from Scotland, but ere they arrived the pioneers had fled. A Spanish force of 1500 men, and a squadron of 11 ships, immediately threatened the new-comers. Captain Campbell marched by night with a body of 200 Scots upon the Spanish camp, which he broke and completely dispersed. On returning to the fort, however, he found it invested by the Spanish squadron. The ammunition of the colonists had now become exhausted, and they were obliged to capitulate, the Spaniards granting honourable terms. Not more than thirty of the colonists, among whom was Paterson, who was rendered for a time insane by his dreadful misfortunes, ever came back to Scotland. The scheme and its collapse caused unprecedented excitement in Scotland from 1695 till 1703, when the last of the adventurers reached home, and contributed to render the union of the kingdoms highly unpopular. It has been fairly contended that, but for the hostility of the king and the jealousy of the English companies, the scheme might have led to enormous extension of British commerce and British territory. And it should be remembered that a Panama Canal was included in the plans of the far-seeing projector. The books and other documents which had belonged to the Company are preserved in the Advocates' Library. See J. H. Burton's *Darien Papers*, printed by the Bannatyne Club (1849), his *History of Scotland*, vol. viii., Warburton's novel *Darien*, and J. S. Barbour's *Paterson and the Darien Company* (1907).

**Dario**, RUBÉN, otherwise Felix Rubén García Sarmiento, Spanish-American poet and prose-writer, was born in 1867 in the Nicaraguan department of Segovia. His wandering career of journalism, amours, and diplomatic appointments began very precociously, and was cut short by pneumonia at León, Nicaragua, 6th February 1916. He had lived much in Chile, Argentina, and Europe. His writings include *Azul* (prose and verse), *Los Raros* (prose, 1893), *Prosas Profanas* (verse, 1896), *Cantos de Vida y Esperanza* (1905), *El Canto Errante* (1907), and an autobiography (1912). Influenced by the Greeks, and especially by the French Parnassians and Symbolists, he gave new metres, a new melody, a new vitality to Spanish poetry, and added to its stores many poems of great beauty, force, and splendour. Sometimes, however, his sumptuousness is overpowering.

**Darius** (*Dāryavus*, Heb. *Dārēyāvesh*), the name of three kings of Persia. **DARIUS I.** (*Hystaspis*), born in 548 B.C., was the son of Hystaspes (Vish-tāspa, in the Babylonian cuneiform *Ustaashpi*), of the family of the Achæmenides, and succeeded to the Persian throne in 521, after putting to death the Magian Gaumâtâ (the Pseudo-Smerdis of the Greeks), who gave himself out to be Bardes, brother of Cambyses. We possess accurate accounts of his reign through a contemporary monument, the great trilingual inscription on the rock of Behistun (q.v.). He is there represented with his foot on the body of Gaumâtâ, and with nine conquered rebels in front of him, the first three from Susiana, Babylon, and Media, the ninth a Scian, with the characteristic pointed hat mentioned in Herodotus, vii. 64. The inscription states that his father, Hystaspes, was the great-grandson of Teispes, who was the son of Achæmenes. Darius had for several years to contend with revolts in all parts of his empire. Babylon resisted him with especial obstinacy under Nidinta-Bel for nearly two years (520-19), and revolting a second time, under Arakha, was again taken (514). He

then reorganised the Persian empire, removing the seat of government to Susa, dividing his dominions into more than twenty satrapies, establishing a regular system of taxation, and providing facilities for communication and trade; while he also pushed his conquests as far as the Caucasus and the Indus. The Indian province paid into the exchequer £1,290,000 a year; Babylonia, £290,000; while other eighteen satrapies contributed altogether £1,674,000. In his expedition against the Scythians in 515, after carrying 700,000 men across the Bosphorus on a bridge of boats, and subduing Thace and Macedonia, he was led on by the retreating Scythians as far as the Volga, and returned to the Danube with the loss of 80,000 of his warriors. He returned to Susa, leaving Megabazos in Thrace with a large part of his army. His first expedition against the Athenians miscarried through the wreck of his fleet at Mount Athos in 492; the second was decisively defeated at Marathon (q.v.) in 490. He died in 485, before the Egyptian revolt (487) had been subdued, and in the midst of his preparations for a third expedition against the Athenians, and was succeeded by Xerxes (q.v.). Darius was a Persian by birth, and bred in the Zoroastrian faith, which under him and his successors became the state religion of the empire. He is mentioned in the Old Testament as permitting (520) the erection of the second temple at Jerusalem, which was completed in the sixth year of his reign (515).

**DARIUS II.** (*Ochus*, called by the Greeks *Nothos*, 'bastard'), illegitimate son of Artaxeies I., in 424 B.C. snatched the crown from Sogdianus, his also illegitimate brother, who had put to death the legitimate brother, Xerxes II. He was entirely under the influence of the eunuchs and women of his harem, especially his cruel and depraved step-sister and spouse Parysatis; and his reign was a long series of miseries and crimes. The numerous revolts were cruelly put down, except that of Amyrteus, satrap of Egypt, who was independent from 414 to his death in 408. After the failure of the Sicilian expedition of the Athenians in 415, Darius seized the opportunity to break the humiliating treaty of 449. Through the satraps of Asia Minor, Tissaphernes and Cyrus, younger son of Darius and Parysatis, he gave so much support to the Spartans against the Athenians in the Peloponnesian war as turned the scale to the side of the former. He died at Babylon in 405, and was succeeded by his eldest son, Artaxerxes II.

**DARIUS III.** (*Codomannus*), the last king of the Persians, son of the Achæmenid Arsanes by Sisymbis, daughter of Artaxerxes II. (q.v.). He is briefly designated as 'Darius the Persian' in Nehemiah, xii. 22, and in the 1st Book of Maccabees is called 'King of the Persians and Medes.' Artaxerxes III. had been poisoned by Bagoas in 338, and the speedy death of his son and successor, Arses, prepared the way for Darius III., who began to reign in the same year as his conqueror Alexander the Great (336). Defeated at the Granicus (334), at Issus (333), and at Arbela (331), the handsome and gentle king was betrayed and slain during his flight by one of his satraps (330). See **ALEXANDER THE GREAT**.

**DARIUS THE MEDE**, mentioned in the Book of Daniel, cannot with certainty be identified with any historical king.

**Darjiling**, or **DARJEELING**, a sanitary station in the Lower Himalayas, and administrative headquarters of Darjiling district, is situated on a narrow ridge, at an elevation of 7167 feet above the sea. It has a fine sanatorium (1883), a good water-supply, and is an increasingly popular summer-resort for visitors and invalids. The fashionable month is October, after the rains, when the clear

atmosphere shows at its best a view of unsurpassed extent and grandeur. Pop. 19,000.—**DARJILING** is the most northerly *district* of the Rajshahi division of Bengal, divided from independent Sikkim by a series of rivers and mountain-torrents; area, 1164 sq. m.; pop. 266,000, mostly Nepalis and other aboriginal or semi-aboriginal tribes, attracted to the district by the increased demand for labour on the railway and in the tea-gardens. With a surface divided between the Lower Himalayas and the marshy sub-montane strip, the scenery of the district is magnificent; up to 12,000 feet the ridges are clothed with valuable forests, and on the higher slopes the rhododendron grows in gorgeous luxuriance. The climate is excessively humid, but not unhealthy. Food-crops are raised, and there is a trade with Tibet and Nepal; but the staple industry is the cultivation of tea. The district suffered from earthquake in 1899.

**Dark Ages.** See AGE.

**Darlaston**, an urban district of Staffordshire, in the parliamentary borough of Wednesbury, with ironworks and coal; pop. 18,000.

**Darley**, FELIX OCTAVIUS CARR, born at Philadelphia 23d June 1822, early gave himself to drawing, and devoted himself especially to book illustration. His earliest important work was a series of drawings for the *Library of Humorous American Works*. He went to New York (1848), where his outline drawings to Washington Irving's *Legend of Sleepy Hollow* and *Rip Van Winkle* spread his reputation. Later works are his illustrations of Judd's *Margaret*, and to Cooper's, Dickens's, and Simms's novels. In 1868, after some years' residence in Europe, he published *Sketches Abroad with Pen and Pencil*. He died 26th March 1888.

**Darley**, GEORGE (1795-1846), poet and mathematician, was born in Dublin, and educated there at Trinity College. Launching himself on literature and on London, he published (1822) *The Errors of Ecstasie*, a blank-verse dialogue between a mystic and a muse. He became one of the writers for the *London Magazine*, in which papers on the English dramatists appeared, as also his best story, *Lilian of the Vale*, with the well-known song, 'I've been roaming.' Some other tales were included in a volume of *Labours of Idleness* (1826). His *Sylvia, or the May Queen* (1827), is mentioned by Lamb as a 'very poetical poem.' And it was about the same date (1826-28) that he produced well-known manuals of geometry, algebra, and trigonometry, as well as a *Geometrical Companion*, with very ingenious illustrations. On the staff of the *Athenæum*, Darley showed himself a severe critic, notably in a savage onslaught on Talfourd's *Ion*. His poems *Nepenthe* and *The Lammergeyer* were circulated privately, and his latter years (clouded by melancholy) saw the publication of two dramas, *Thomas à Becket* (1840) and *Ethelstan* (1841). A profound student of the older English literature, he edited Beaumont and Fletcher's plays in 1840; and so greatly was his style influenced by 17th-century models that Palgrave inserted in the *Golden Treasury* his fine verses, 'It is not Beauty I demand,' as the work of an anonymous writer of that age. His poems were edited by Ramsay Colles in 1908.

**Darling**, a tributary of the Murray River (q.v.).

**Darling**, GRACE, was the daughter of William Darling (1795-1860), lighthouse-keeper on Longstone, one of the Farne Islands, and was born at Bamborough, 24th November 1815. Before dawn on the morning of the 7th September 1838, the *Forfarshire*, bound from Hull to Dundee, with sixty-three persons on board, struck among the Farne Islands, and in fifteen minutes forty-three

persons were drowned. Darling and his daughter, at great risk, brought their boat to where the nine survivors crouched, and with help from the shipwrecked crew, the solitary woman and four men were safely taken to the Longstone; two of the men returned with Darling, and succeeded in bringing the remainder. The brave deed provoked much enthusiasm; father and daughter received medals and large gifts, and Grace became a heroine. But she did not long survive her exploit, dying of consumption, 20th October 1842. See *Grace Darling, her True Story* (1880), and her father's *Journal* (1886).

**Darling**, SIR RALPH (1775-1859), who served in the West Indies and was deputy adjutant-general in the Walcheren Expedition, was governor of New South Wales in 1825-31. He was accused of excessive severity and of favouritism in disposing of crown-lands, was recalled, but acquitted by a parliamentary committee, and knighted. After him have been named the river Darling; the Darling Range, in Western Australia (q.v.); the Darling district in the south-western corner of New South Wales; and the Darling Downs, the richest district of Queensland, an upland country on and about the summit of the Dividing Range.

**Darlington** was in the 12th century known as Dernington, and was later shortened to Dertoun (where the Scottish poet Dunbar in the 15th century describes himself as having preached) or to Darnton. It is a parliamentary and county borough in the south of the county of Durham, on a slight elevation overlooking the Skerne near its junction with the Tees, 23 miles S. of Durham, and 45 NNW. of York. The chief industry of the place is connected with the extensive locomotive works, which give employment to many workers. There are iron and steel works, works for iron and steel bridge-making, for railway wagons, iron and brass foundries, breweries, tanneries, and wool-mills. Pop. (1821) 6551; (1851) 11,228; (1881) 35,102; (1921) 65,866, of whom many are connected with the Society of Friends, long a prominent and influential element amongst the inhabitants. Darlington was in 1867 created a parliamentary borough, sending one member to parliament. Its prosperity dates from the opening, on 27th September 1825, of the Stockton and Darlington Railway, which was the first passenger-line on which a locomotive-engine was employed; and that locomotive now stands on a pedestal inside the station. From the 11th century onwards the town belonged to the bishops of Durham, and till 1867 a borough bailiff, appointed by the bishop, managed its affairs; in that year it obtained a charter of incorporation. St Cuthbert's collegiate church, a very fine specimen of Early English, was founded in 1160 by Bishop Pudsey, and was restored by Sir G. G. Scott in 1869. It has three beautiful sedilia, and a tower 180 feet high. Among the chief modern erections are the other churches (Anglican, Presbyterian, Roman Catholic, and other), the spacious railway station, a grammar-school, a high school for girls, a British and Foreign School Society's college for female teachers, and a technical college. A free library was opened in 1885, for which Mr Edward Pease had bequeathed £10,000. At Oxen-le-field, 3 miles from Darlington, are curious cavities of unknown origin, called Hell Kettles; and near Darlington was the seat of George Allan the antiquary (1736-1800).

**Darlingtonia**, a genus of one species, an American Pitcher-plant, belongs to the family of Sarraceniaceæ (q.v.). See INSECTIVOROUS PLANTS.

**Darmesteter**, JAMES (1849-94), orientalist, was born at Château-Salins, department of Moselle (Lorraine), of a Jewish family originally—as the name indicates—from Darmstadt. He was edu-

cated at Paris, in 1875 wrote a thesis on the Avesta, crowned by the Institute, and became a conspicuous member of the Société Asiatique. He was professor of Zend at the Ecole des Hautes Études (1877) and at the Collège de France (1885). In 1883 he published *Études Iranienues*, followed by works on the Mahdi, on Persian popular poetry, and on Afghan folk-songs (the fruits of a government mission to India). His principal works were a series of books on the Zend-Avesta, including a translation of the great part of it in *The Sacred Books of the East*. He held that much of the Avesta has a late origin (see ZEND). In a volume on the Hebrew Prophets, he advocated a return to Hebrew monotheism. He also wrote *Essais de Littérature Anglaise*, edited two volumes of philological articles by his brother Arsène, and translated into rhythmical French a selection of the poems of Agnes Mary F. Robinson, whom he married in 1888. Mme. Darmesteter was born at Leamington in 1857. In 1901 she married Professor Duclaux, who died in 1904. She has written a long series of books of admirable poetry, lyrical and other, translations from Euripides, a novel (*Arden*), and *Lives of Emily Brontë* (1883), Renan (1897), Hugo (1921), &c.—His brother, ARSÈNE (1846–88), trained to be a rabbi, passed to the study of mediæval French, in which he soon became the recognised authority, and began the great dictionary in collaboration with M. Hatzfeld.

**Darmstadt**, a town of Germany, capital of Hesse, on the small river Darm, 15 miles S. of Frankfurt-on-Main. The streets of the old town are narrow, but those of the new town exhibit many imposing specimens of architecture. Darmstadt has several public squares, and fine public gardens and promenades. Besides the arsenal, the barracks, and the various religious edifices, it possesses two palaces. One of these, the old ducal palace, contains museums of painting, natural history, and archaeology, and a library of 600,000 volumes; in the other, Prince Charles's palace, is Holbein's famous 'Meyer Madonna.' The post-office dates from 1881, the theatre from 1871, the museum from 1905. There are manufactures of chemicals, iron, and machinery; and a trade in iron, petroleum, fruit, flour, and wine. But the place depends more on its government offices than on its industries. Pop., with suburb of Bessungen, (1875) 44,088; (1890) 56,399; (1900) 72,381; (1910) 87,089; (1919) 83,550.

**Darnel** (*Lolium temulentum*), an annual grass of the same genus with Rye-grass (q.v.), common as a weed in cornfields in England and many parts of Europe. Probably the tares of the parable, it is reputed (though some authorities deny the fact) to have a narcotic poisonous seed. See RAPHAŊIA.

**Darnétal**, a town in the French department of Seine-Inférieure, 2½ miles E. of Rouen, with manufactures of cotton and woollen goods, dye-works, bleach-works, &c.; pop. 7300.

**Darnley**. See MARY QUEEN OF SCOTS.

**Dart**, a river of S. Devonshire, flows 35 miles south-eastwards from Dartmoor to the English Channel, which it enters by an estuary on which stands Dartmouth.

**Darter** (*Plotus*), a genus of fresh-water diving birds nearly related to the cormorants, represented in warm regions of America, Africa, Asia, and Australia. As in cormorants, gannets, and pelicans, the four toes are united in a web. The bill is long and sharp, the edges of the mandibles are serrated, and there is a very remarkable spring-like arrangement in the neck—all adaptations to the fish-catching habits. The American species (*Plotus ankinga*) is often called the snake-bird.

The darters have a laboured flight, but swim and dive to perfection. They are sociable birds, and usually nest in colonies, on trees and bushes near the water.

**Dartford**, a thriving urban district of Kent, in the narrow valley of the Darent, 2 miles above its influx to the Thames, and 17 ESE. of London. Edward III. here founded an Augustinian nunnery (1355); St Edmund's chantry was a great place of pilgrimage; and at Dartford Wat Tyler commenced his rebellion (1381). The church, with a Norman tower, was restored in 1863; among its interesting monuments is one to Sir John Spielman, Queen Elizabeth's jeweller, who in 1588 established at Dartford what is said to have been the first paper-mill in England. Paper is still manufactured, besides steam-engines and machinery, gunpowder, &c. The modern buildings include a county court-house (1859), assembly-rooms (1860), a physical training college, and, in the neighbourhood, two great mental hospitals. Pop. (1851) 6224; (1881) 10,163; (1921) 26,005.

**Dartmoor** is a great granitic upland in Devonshire, the source, with two exceptions, of all the principal rivers of the county, remarkable alike for its wild and rugged scenery, its antiquities, its wide, solitary, trackless wastes, and its mineral products. It is upwards of 130,000 acres in extent, the extreme length from north to south being 25 miles, and the extreme breadth from east to west 20 miles. The outline is irregular. The central portion is the ancient royal forest of Dartmoor, and this is surrounded by a belt of open country, once known as the 'Commons of Devonshire,' portions of which have been inclosed. The attempts to cultivate Dartmoor itself have been very few, and the northern quarter for miles shows no trace of man, but the valleys through which the rivers descend to the lowland country are singularly fertile, and at times full of beauty. The moor itself affords valuable mountain pasture to cattle, sheep, and large numbers of half-wild ponies. The forest rights belong to the duchy of Cornwall; but there are rights of pasture exercised by holders of what are called venville tenures in certain parishes bounding the moor, which date prior to the Norman Conquest.

The average height of Dartmoor above the sea is upwards of 1200 feet, but its highest point, High Willhayes, is 2039 feet; and the next, Yes Tor, 2028. The hills are commonly called *tors*, and for the most part have granite crests, weathered into grotesque and picturesque shapes. The whole of Dartmoor is of granite, protruded between the close of the Carboniferous and the opening of the Triassic period. Devonian rocks mantle round its southern extension, and Carboniferous round its northern, associated at various points with gabbros, dolerites, and other intrusive rocks. The granite is chiefly gray, but there are rich red varieties, as at Trowlesworthy. Large quantities of the ordinary stone have been quarried, especially at Hey Tor and King Tor. Dartmoor is rich in minerals. Tin has been raised for many centuries, long before the dawn of history, by streaming in the valleys, and vestiges of the ancient mining operations of the 'old men' abound. Copper, iron, and manganese have also been worked, but mining is now carried on at a few points only. Gold has frequently been found in the river-beds. The tinners of Devon had a quasi-corporate existence in Saxon times, and their rights were confirmed by King John and other monarchs. The Stannary Parliaments, in which they managed their affairs, were held in the open air on Crockern Tor. The most important mineral product of Dartmoor at the present day is china-clay, or kaolin, which is the result of the decomposition of the felspar

of the granite. The largest china-clay works in England are at Lee Moor, and are connected by a tramway with wharves at Plymouth.

The fauna and flora of Dartmoor have many points of interest. Trees are very rare; but there is a very singular group of gnarled and stunted oaks on a slope overlooking the West Dart, near Crockern Tor, of high antiquity and weird aspect, which has been called one of the 'wonders of the moor'—'Wistman's Wood.'

The chief rivers rise at a height of over 1800 feet above the sea, in a wide stretch of peat-bog around Cranmere Pool—the Dart, Teign, Taw, Okement, Lyd, Tavy, and Walkham. From the morasses of the southern quarter spring the Plym, Yealm, Erme, and Avon.

Dartmoor is unrivalled in England in the extent and character of its prehistoric and rude stone antiquities—earthworks, barrows, kistvaens, menhirs, lines or avenues, cyclopean bridges, circles, trackways, and pounds or enclosures of stones, sometimes containing the remains of villages. Many stone implements have been found. On several of the tors there are rock basins, formerly called Druidical, but now assigned to the operation of natural causes.

The chief centre of population is Prince Town, named after George IV. when Prince Regent. Here a prison was built (1806) during the war with Napoleon, for the reception of prisoners of war. When the war ended it was abandoned, and was at one time used for the manufacture of naphtha from peat, which failed. In 1850 the buildings were adapted to the purpose of a convict prison. Attached is a fertile reclaimed farm. A very picturesque railway runs to Prince Town.

See Rowe's *Perambulation of Dartmoor* (1856; 3d ed. 1896); Beatrix F. Cresswell, *Dartmoor and its Surroundings* (1898); Baring-Gould, *A Book of Dartmoor* (1900); and the writings of Eden Phillpotts.

**Dartmouth**, a seaport and municipal borough (till 1867 also parliamentary) in the south of Devonshire, 32 miles S. by W. of Exeter. It is built in picturesque terraces on a steep slope 300 to 400 feet high, on the right bank of the romantic estuary of the river Dart, at a short distance from the sea. The streets are narrow, and many of the houses very old, with overhanging stories, projecting gables, and wood-carvings. St Saviour's Church (*circa* 1372) has a richly sculptured, painted, and gilt stone pulpit, and a beautifully carved rood-loft. A battery, and the remains of a castle built during the reign of Henry VII., stand at the entrance to the harbour. Pop. 7000. Dartmouth has a Royal Naval College (1905) and some trade. It builds yachts and boats, and is a favourite yachting station—the harbour being deep and landlocked. On the other side of the river is Kingswear, the terminus of a branch of the Great Western Railway. At Dartmouth, in 1190, the Crusaders, under Richard Cœur-de-Lion, embarked for the Holy Land. The French burned it in Richard's reign, but were repulsed, chiefly by the women, in an attack in 1404. In 1346 Dartmouth furnished 31 ships for the siege of Calais. In 1643 Prince Maurice besieged and garrisoned it; but in 1646 Fairfax stormed and took it. Sir Humphrey Gilbert, John Davis, and Newcomen may be accounted Dartmouth worthies, as having been born in or quite near the town (see the articles on them). Dartmouth has now a share in training naval cadets (see NAVY).

**Dartmouth College.** See HANOVER (U.S.).

**Daru**, PIERRE ANTOINE, COMTE, writer and financier, born at Montpellier 12th January 1767, entered the army, but was imprisoned during the Terror. Under Napoleon he was Intendant-

general in Austria and Prussia, and a councillor of state, while in 1818 Louis XVIII. made him a peer. Thenceforth he devoted himself exclusively to letters. He died a member of the Institute and of the Academy of Sciences, 5th September 1829. Of his many books the chief are *Cleopédie* (1800), a spirited poem; *Histoire de la République de Venise* (7 vols. 1819-21); and *Histoire de la Bretagne* (3 vols. 1826).—His son, NAPOLEON DARU (1807-90), opposed the *coup d'état*, and was proscribed; but became a member of the National Assembly in 1871, of the senate in 1876.

**Darwaz.** See BOKHARA.

**Darwen**, a municipal borough of Lancashire, on the river Darwen, 3½ miles S. of Blackburn, and 9 N. of Bolton. Cotton is the staple manufacture; then come paper-making and paper-staining; and to these and other industries, with its water facilities, and the neighbouring coal-mines and stone quarries, Darwen owes its rapid growth and its well-being. It was incorporated in 1878. Chief buildings are the free library, market hall, co-operative hall, and the public baths, erected in memory of Sir Robert Peel. Pop. 38,000.

**Darwin.** See PORT DARWIN.

**Darwin**, CHARLES ROBERT, naturalist, the discoverer of the principle of natural selection, was born at Shrewsbury, February 12, 1809. His grandfather was Dr Erasmus Darwin, and his father Dr Robert W. Darwin, F.R.S. His mother was a daughter of Josiah Wedgwood, the celebrated potter. Darwin was educated at Shrewsbury grammar-school, studied at Edinburgh University for two sessions in 1825-6-7, and entered at Christ's College, Cambridge, in 1828. Already at Edinburgh he had become a member of the local Plinian Society; he took part in its natural history excursions, and read before it his first scientific paper—a new contribution to our knowledge of the *Flustra* or sea-mats. It was at Cambridge, however, that his biological studies seriously began. Here he became acquainted with Professor Henslow, the well-known botanist, who encouraged his interest in botany and zoology. His chief taste at this time was for geological research. In 1831 he took his degree of B.A., and shortly after was recommended by Henslow as naturalist to the expedition of H.M.S. *Beagle*, under Captain (afterwards Admiral) Fitzroy, R.N., then about to start for a scientific survey of South American waters. He sailed on 27th December 1831, and did not return to England from his long cruise till 2d October 1836. Meanwhile he visited Teneriffe, the Cape Verde Islands, the Brazilian coast, Monte Video, Tierra del Fuego, Buenos Aires, Valparaiso, and the Chilean region, the Galápagos Archipelago, Tahiti, New Zealand, Tasmania, and the Keeling Islands, in which last he laid the foundation for his famous theory of coral reefs. It was during this long expedition that Darwin obtained that intimate knowledge of the fauna, flora, and geological conditions of many tropical, subtropical, and temperate climates which so admirably equipped him at last for the great task he was afterwards to perform in settling the factors of biological evolution.

On his return to England in 1836, he set to work to co-ordinate the results obtained during his voyage. He formed the friendship of Sir Charles Lyell and other scientific leaders, by whose aid he was appointed secretary of the Geological Society in 1838. A year later, he was elected to the fellowship of the Royal Society, and early in 1839 he married his cousin, Miss Wedgwood. In the same year he published his *Journal of Researches into the Geology and Natural History of the various Countries visited by H.M.S. Beagle*. From 1840 to 1843 Darwin was occupied with the publication of the *Zoology of the*

*Voyage of the Beagle*, under government auspices, to which great work (compiled by the leading specialist authorities of the day) he himself contributed an introduction and many notes. In 1842 appeared his work on *The Structure and Distribution of Coral Reefs*; in 1844, *Geological Observations on Volcanic Islands*; and in 1846, *Geological Observations on South America*. These works placed him at once in the front rank of contemporary scientific thinkers. In 1851-53 appeared his valuable treatise on barnacles, *A Monograph of the Cirripedia*.

Three years after his marriage Darwin settled at Down, near Beckenham, in Kent, where for the rest of his days he passed his time as a country gentleman among his conservatories, his pigeons, his garden, and his fowls. The practical information thus gained (especially as regards variation and interbreeding) was of invaluable use to him in his later researches. Private means enabled him to devote himself unremittingly henceforth, in spite of continuous and distressing ill-health, to the pursuit of science. It was at Down that Darwin began to occupy himself with the great work of his life—the problem of the origin of species. In 1837 he had already set out to accumulate facts and observations for this purpose. After five years' unremitting work, he 'allowed himself to speculate' on the subject, and drew up some short notes, which he enlarged in 1844 into a sketch of conclusions for his own use. These conclusions embodied in embryo the famous principle of natural selection, the germ of the celebrated Darwinian Theory (q.v.). With constitutional caution, however, Darwin delayed publication of his hypothesis, which was only at length precipitated many years later by an accidental circumstance of a romantic character. In 1858 Mr Alfred Russel Wallace, the distinguished explorer, sent home from the Malay Archipelago a memoir addressed to Darwin himself, for presentation to the Linnean Society. On opening this packet, Darwin found to his surprise that it contained in essence the main idea of his own theory of natural selection. Sir Charles Lyell and Sir Joseph Hooker, to whom he communicated the facts, persuaded Darwin to read a paper of his own concomitantly with Wallace's before the Linnean Society, which was accordingly done on July 1, 1858. Urged forward by this strange coincidence, Darwin set to work seriously at once to condense his vast mass of notes—the labour of a lifetime—and put into shape his great work on *The Origin of Species by means of Natural Selection*, published in November 1859. For an account of the main ideas there promulgated, see DARWINIAN THEORY. The book itself, an epoch-making work, was received throughout Europe with the deepest interest, was violently attacked and energetically defended, but in the end succeeded in obtaining recognition (with or without certain reservations) from almost all competent biologists. From the day of its publication Darwin continued to work on unremittingly at a great series of supplemental treatises, in which his main principles were still further enforced and enlarged, while minor corollaries were brought prominently into view. *The Fertilisation of Orchids* appeared in 1862, *The Variation of Plants and Animals under Domestication* in 1867, and *The Descent of Man* in 1871. The last-named work, hardly less famous than the *Origin of Species*, derives the human race from a hairy quadrumanous animal belonging to the great anthropoid group, and related to the progenitors of the orang-utan, chimpanzee, and gorilla. In this book Darwin also developed his important supplementary theory of sexual selection, which on the whole has been received by scientific thinkers with less favour than his other ideas. His later works are *The*

*Expression of the Emotions in Man and Animals* (1873), *Insectivorous Plants* (1875), *Climbing Plants* (1875), *The Effects of Cross and Self Fertilisation in the Vegetable Kingdom* (1876), *Different Forms of Flowers in Plants of the same Species* (1877), and *The Power of Movement in Plants* (1880). His last work, *The Formation of Vegetable Mould through the action of Worms*, appeared in 1881. In it Darwin showed grounds for believing that the vegetable mould which covers a large part of the globe is mainly due to the castings of earth-worms, without which the greater portion of the land surface of the world must necessarily consist of barren rock or thirsty sand.

It is, however, as the great leader of evolutionary biology that Darwin will be mainly remembered among men. Though not (as is commonly, but erroneously, believed) himself the originator of the evolution hypothesis, nor even the first to apply the conception of descent with modification to plant and animal organisms, Darwin was undoubtedly the first thinker to gain for that conception a wide acceptance among biological experts. By adding to the crude evolutionism of Erasmus Darwin, Lamarck, and others, his own specific idea of natural selection, he supplied to the idea a sufficient cause, which raised it at once from the level of a hypothesis to the grade of a verifiable theory. His kindness was as striking as his honesty and devotion to truth. He died 19th April 1882, and was buried in Westminster Abbey.

See his *Life and Letters* (1887; with *More Letters*, 1903) by his son, SIR FRANCIS, F.R.S. (1848-1925), botanist, president of the British Association in 1908.—An elder son, SIR GEORGE HOWARD, F.R.S., K.C.B. (1845-1912), from 1883 professor of Astronomy at Cambridge, distinguished for his work on tides, tidal friction, the equilibrium of rotating masses, and geodesy, was president of the British Association in South Africa in 1905. See his *Tides* (1898) and *Collected Papers* (1908-11).

**Darwin, ERASMUS**, was born 12th December 1731, at Elston Hall, near Newark; entered St John's College, Cambridge, in 1750, and studied medicine at Edinburgh. After an unsuccessful attempt to establish a practice at Nottingham, he removed to Lichfield, where he married and became a popular physician and prominent figure from his ability, his radical and free-thinking opinions, his poetry, his eight-acre botanical garden, and his imperious advocacy of temperance in drinking. After his second marriage in 1781, he settled in Derby, and then at Breadsall Priory, where he died suddenly 18th April 1802. Darwin had once a great reputation as a physiologist, but his system is, for the most part, inconsistent, baseless, and untenable. At the same time, many of his ideas are original, suggestive, and contain within them the germs of important truths. His strength and his weakness lay in his faculty for seeing analogies in nature. Sometimes he is exceedingly happy in his discoveries; at other times he is quite fantastical. The same remarks hold good as regards his verse, where, amid the frequent extravagance and incomprehensibility of his notions, there burst forth strains of genuine poetry. *The Loves of the Plants* (1789), a part of his chief poem, the *Botanic Garden*, was happily burlesqued in the 'Loves of the Triangles' in the *Anti-Jacobin*. Interest in Darwin's speculations has been revived by the recognition of his partial anticipation of Lamarck's views on evolution, and so of his own famous grandson's. His chief works are *Zoonomia* (1794-96), and his *Phytologia* (1799). See his *Life* by Charles Darwin, prefixed to Krause's essay (1879), and works by Brandl (1902 and 1909). By his first wife he was grandfather of Charles Darwin; by his second, of Francis Galton.

**Darwinian Theory**, the explanation of the evolution of forms of life on our planet, offered by the great naturalist, Charles Darwin (q.v.). From the very outset we must carefully guard against the confusion, still widely popular, of 'Evolution' with 'Darwinism.' Evolution must clearly be retained to denote the entire drama of cosmic change; Darwinism, therefore, must as clearly be restricted to one particular interpretation of the mechanism and plot of this cosmic drama, of many which have been thrown out by reflective spectators. Darwin expressed the mode of the evolutionary process in a classic phrase, the title of his great work—*The Origin of Species by means of Natural Selection, or the Preservation of Favoured Races in the Struggle for Life*. That explanation is not only in itself peculiarly shrewd and well reasoned, luminous and widely applicable, but has been of the very greatest importance in awakening biologists and students of all other sciences, and thus ultimately the intelligent public, to the facts of the case—to the consciousness of this evolutionary drama. On the promulgation of this new hypothesis as to the mode of occurrence of evolutionary changes in the organic world, the whole discussion as to the occurrence of evolutionary change at all speedily came to centre round it; although in view of the powerful arguments for the occurrence of evolution which had been independently adduced by Spencer and others, it may be admitted this was not quite logical. The fact, however, remains. Moreover to the new standpoint afforded by the clear acceptance of both ideas—evolution and this through natural selection—and to the energetic application of these, first by Darwin himself, but soon by a multitude of zealous workers, we owe a progress which it would as yet be premature to estimate, but which has pervaded the whole field of biology, and even the fields of all the higher sciences, mental and social, which so largely utilise biological methods and generalisations. Whatever may be the subsequent development of our evolutionary conceptions, the epoch-making importance of the Darwinian theory will be unaltered. Hence the expediency of the present comparatively full exposition of its main positions and of their bearings, apart from the larger and more general argument under EVOLUTION.

To the statement of Darwin's theory, therefore, we may at once proceed, postulating no more than that general acquaintance with the aims and results of biology which is now becoming so commonly current, or which may readily be gained by help of the articles BIOLOGY and BOTANY. Nor need any statement of the general doctrine of evolution, or of evolutionary theories before Darwin, here detain us, since these find more fitting place in the general article EVOLUTION.

The failure of pre-Darwinian theories to gain any very general acceptance among naturalists was no doubt largely attributable to established prejudice, backed as this was by the predominant authority of Cuvier. This was by no means the whole explanation. For while those theories rendered it extremely probable that modification had occurred, they all fell short, as Darwin pointed out, in one most important particular. They failed to show how the modification of one species from another could take place, 'so as to acquire that perfection of structure and co-adaptation which justly excites our admiration;' since the hypotheses of the potency of external conditions, of habit, of the volition of the organism itself, and so on, alike successively broke down.

Darwin was especially struck by the distributional phenomena he witnessed during his 'Naturalist's Voyage,' and thereafter devoted himself primarily to the problem of the origin of

species, specially concentrating himself upon what seemed to him the weakest point of the preceding theories, the explanation of adaptations. Commencing in 1837, 'after five years' work, I allowed myself to speculate on the subject, and drew up some short notes; these I enlarged in 1844 into a sketch of the conclusions which then seemed to be probable; from that period to the present day I have steadily pursued the same object.' This was written as late as 1859, and even then because he had received a paper from A. R. Wallace (at that time exploring the Malay Archipelago), in which views identical with his own were expressed, and thus was compelled to proceed to the publication of his results. He did so first in a brief outline read, by advice of Lyell and Hooker, simultaneously with Wallace's paper (see *Jour. Linn. Soc.*, 1858); and in the following year in that fuller abstract, as at first he merely regarded it, which soon became so famous—the *Origin of Species*. Its substance may with advantage be briefly summarised, so far as further compression of such 'intellectual pemmican' is possible. For details and explanations the reader must consult the work itself (7th ed. 1880).

*Outline of 'Origin of Species.'*—In order to gain insight, then, into the means of modification, Darwin commences with a study of the variation of plants and animals under domestication (later expanded into a separate work; 2d ed. 1876).

*Variation and Heredity.*—While all plants and animals exhibit some degree of variation, this is greatest among domesticated species, owing to their new and less uniform conditions of life. These may act directly on the whole organisation, or on separate parts, and the variation, though rarely, is sometimes definite, as when size increases with quantity of food, or colour changes with its quality; or the conditions may act indirectly by influencing the reproductive system, which is peculiarly sensitive. Changed habits produce an inherited effect—e.g. the leg-bones of the common duck weigh proportionally more, and its wing-bones less, than in the wild variety, because it flies less and walks more. So, too, tame mammals acquire drooping ears, since these are rarely pricked in alarm. One variation is usually correlated with others, thus long-beaked pigeons have small feet, and conversely. All variations tend to be inherited. The popular belief that domestic races simply revert to the aboriginal stock is unsupported by facts.

Save that domestic varieties are less uniform than wild species, often differ more widely in some single part, and are fertile when crossed, there is no well-marked distinction between these and so-called true species. If, therefore, such varieties as the different breeds of the dog can be shown to be descended from a single wild species, there necessarily arises great doubt as to the immutability of closely allied natural species, such as the foxes. While, however, the many breeds of dog appear to have arisen from several wild species, and those of cattle also from two or three, our fowls, ducks, rabbits, &c., all certainly arise from a single ancestral species. The case of pigeons is of peculiar importance, since pouter, carrier, fantail, and tumbler differ so thoroughly, externally and internally, that any ornithologist would be compelled to assign to them not merely specific but generic distinctness, if he had discovered them in the wild state. There is at least as much difficulty in believing that such breeds can have proceeded from a common ancestor, as there is in the case of any group of birds in nature; and every breeder of these has been firmly convinced of their descent from distinct species. Yet all these breeds are proved to come from the common rock-dove (*Columba livia*; see PIGEON),

and thus those who admit the unity of domestic races should be cautious in deriding the unity of wild ones.

Domestic races all exhibit adaptations to man's use or fancy, rather than to their own good. The key to this is man's power of selection: nature gives successive variations, man accumulates these, so making for himself useful breeds, and often (e.g. in sheep, cattle, roses, dahlias) profoundly modifies their character even in a single human lifetime; so that in all characters to which he attends, they may differ more than the distinct species of the same genera. Again, that unconscious selection which results from every one trying to possess and breed the best animals is yet more important than conscious selection. Two flocks of Leicester sheep, kept equally pure, appeared of quite different varieties after fifty years. Such slowly accumulated change explains why we know so little of the origin of domestic races; and its absence in regions inhabited by uncivilised man explains why these yield no plants worth immediate culture. Human selection is facilitated (1) by the keeping of large numbers, since variations will be more frequent, and (2) by preventing free-intercrossing; some species vary, however, more than others.

*Variation under Nature.*—All similar organisms in nature present individual differences, more considerable than is usually supposed. No two blades of grass are alike, and far more marked differences often occur, several castes or varieties sometimes existing in the same sex. Between these castes, and much more frequently between forms which systematic botanists and zoologists rank as true species, perfectly intermediate forms may occur. No agreement about the definition of species (the amount of difference necessary to give any two forms specific rank) has ever been come to; thus, in the British flora alone, there are nearly two hundred disputed forms, and individual opinion is in these cases the only criterion. As long as a genus is imperfectly known, and its species founded upon few specimens, they appear clearly limited. But with fuller knowledge, intermediate forms come in, and doubts as to specific limits augment. The terms species and variety are thus arbitrarily given to sets of individuals more or less closely resembling each other. See VARIATION, SPECIES, GENUS.

Individual differences are thus of the highest importance, as the first steps towards the slightest varieties worth recording, these in turn towards more distinct and permanent varieties, these varieties again towards sub-species, and in the next stage to species; though extinction may often arrest the process.

The species which present most varieties are those which have the greatest geographical range, or the widest diffusion in their own territory, or which possess the greatest number of individuals. In the larger genera of each country the species vary more frequently than in the smaller genera; and in many respects the species of large genera present a strong analogy with varieties, which analogy is intelligible chiefly on the view that they once existed as mere varieties themselves.

*Struggle for Existence.*—All organic beings tend to increase with extreme rapidity, so that if they were not kept down, the earth would soon be covered by the progeny of a single pair. This is evidenced not merely by calculation, but by actual observation of the extraordinary rapidity with which plants and animals have spread, when introduced into new and favourable circumstances (e.g. thistles and rabbits into Australia).

Since organisms then are reproducing themselves so rapidly, and since all their offspring cannot escape their enemies, get food, and live, much less

leave progeny in turn—since, in other words, the doctrine of Malthus applies to animals and plants with manifold force (for these can have no artificial increase of food, and no prudential restraints on reproduction)—there must in every case be a *struggle for existence*, either of one individual with another of the same species, or with the individuals of distinct species, or with the physical conditions of life; often, indeed, with all these at once, and that more or less intensely throughout the whole of life.

The checks which prevent increase are most obscure, and vary in each case. In all cases the amount of food, of course, gives the extreme limit. The youngest organisms generally suffer most; seedlings, for instance, are destroyed in vast numbers. Thus, even in a patch of ground purposely dug and cleared, where no choking from other plants could take place, 295 out of 357 seedling-weeds were destroyed, chiefly by slugs and insects. So, too, the stock of game on an estate depends chiefly upon the destruction of vermin. Climate, however, is highly important, and periodic seasons of extreme cold and drought seem the most effective of all checks—a severe winter sometimes destroying four-fifths or more of the birds of a locality. Epidemics, too, may occur, especially where numbers have inordinately increased. On the other hand, a large number of individuals of the same species is essential for its continued preservation.

The complex relations of all animals and plants to each other require illustration. The planting of part of a heath with Scots pine leads to a profound alteration of its flora and fauna, while the growth of these pines again is wholly dependent upon the exclusion of cattle. Many flowers depend for fertilisation on the visit of a special insect—e.g. red clover on humble-bees. But bees are destroyed by field-mice, and consequently protected by cats; hence, not only no bees, no clover, but also the more cats, the more clover! The struggle for life is most severe between type forms and varieties of the same species, and between the species of the same genus, since these tend to fill the same place in the economy of nature; hence we see the brown rat supplanting the black, and the hive-bee supplanting its Australian congener. The structure of every being is related to that of the others with which it competes, or from which it seeks to escape, or on which it preys; as is alike evident in the structure of the tiger and of the parasite which clings to his hair. So, too, the endosperm of a seed is chiefly useful in favouring the young plant's struggle for light and air against the adult plants around.

*Natural Selection.*—But how will the struggle for existence act with regard to variation? Can the principle of selection, so potent in the hands of man, apply under nature? Most efficiently so. Let us bear in mind (1) the constant occurrence of variation; (2) the infinite complexity of the relations in which organisms stand to each other, and to the physical conditions of life; and consequently (3) what infinitely varied diversities of structure might be useful to each being under changing conditions of life. Can it then be thought improbable, seeing that variations useful to man have undoubtedly occurred, that other variations useful in some way to each combatant in the great and complex battle of life should also occur in the course of many generations? And if such do occur, can we doubt (remembering that many more individuals are born than can possibly survive) that individuals having some advantage, however slight, have the best chance of surviving and of reproducing their kind, while injurious variations are destroyed? This preservation of favourable variations, and the destruction of injurious ones,

is termed Natural Selection, or less figuratively, the Survival of the Fittest.

Taking the case of a country undergoing a change of climate, the proportional numbers of its denizens would change, some species probably becoming extinct—and these changes would in many ways affect the survivors. A further disturbance would come from the immigration of new forms; or if that were prevented, we should have places in the economy of nature which might be better filled up. Any slight favourable modification of the old species would tend to be preserved, and we have seen that changed conditions increase variability.

Nor are such changes necessary in order to leave places for natural selection to fill. No country can be named where the native inhabitants are perfectly adapted to their conditions and competitors, for as some foreigners have taken firm possession in every country, we may safely conclude that the natives might have been modified with advantage to resist them.

And when human selection has produced such great results, why may not natural? Human selection acts only for man's own good, on mere external and visible characters, and irregularly throughout a short period; natural selection acts for the good of the being itself, on the whole machinery of its life, and incessantly on the species, throughout almost infinite time. (It is important here to remember that the objection to this agency on the ground of its presumed insignificance, is identical with that so long but unsuccessfully employed against Lyell's explanation of the origin of the physical features of the globe by summing up the existing natural changes.)

Natural selection thus leads to the improvement of each creature in relation to its organic and inorganic conditions of life, and consequently in most cases to what must be regarded as an advance in organisation. Nevertheless, low and simple forms will long endure, if well fitted for their simple conditions.

Natural selection may modify the egg, seed, or young, as easily as the adult, and these modifications may affect through correlation the structure of the latter, and conversely.

Besides Natural, we have to consider Sexual Selection—i.e. not merely do individuals struggle for existence, but the males struggle for the females, and the most vigorous thus tend to leave most progeny. Special weapons, offensive and defensive, like the cock's spurs, the stag's horns, or the lion's mane, are used in this struggle, and the most useful variations are those which are transmitted. Again, just as man can in a short time give beauty to his domestic birds, so there is no good reason to doubt that female birds in thousands of generations, by selecting, as they are observed to do, the most melodious or beautiful males, might produce a marked effect, and many sexual differences are thus explained.

The theory of natural selection may be applied in special cases—e.g. (1) to explain the evolution of swift greyhound-like varieties of wolves; (2) to explain the origin and the excretion of nectar in flowers, its use to insects, the action of insects in transferring pollen from flower to flower, with its advantage in intercrossing; and the resultant modification and adaptation of flower and insect to each other by the preservation of advantageous variations.

The circumstances favourable to the production of new forms through natural selection are also reviewed. These are chiefly, great variability; large numbers of individuals; the complex effects of intercrossing; isolation in small areas, yet also extension over continental ones, especially if these

vary in altitude; and considerable lapse of time. Rare species are shown to be in process of extinction. The *divergence of character* in domestic breeds, largely due to the fact that 'fanciers do not, and will not, admire a medium standard, but like extremes,' applies throughout nature, from the circumstance that the more diversified the descendants from any one species become in structure, constitution, and habits, by so much will they be better enabled to seize on many and widely diversified places in nature, and so to increase in numbers. Thus, taking a carnivorous animal which has reached the maximum numbers its territory will support, it is evident that it can succeed in increasing only by its varying descendants seizing places hitherto occupied by other animals. This must hold equally of all species, and is separately demonstrated for plants. The greatest amount of life can be supported by help of proportionally great diversification of structure; hence, in small areas where competition is severe, the inhabitants are extremely varied.

The probable effects of the action of Natural Selection, through divergence of character and extinction, on the descendants of a common ancestor are then discussed in detail by Darwin with an illustrative diagram. This takes the form of a genealogical tree—the great tree of life, which fills with its dead and broken branches the crust of the earth, and covers the surface with its ever-branching and beautiful ramifications.

*Laws of Variation* (see VARIATION).—Of the cause of most variations we are still ignorant, but the same laws appear to have acted in producing the lesser differences between varieties of the same species and the greater differences between species of the same genus. Changed conditions sometimes induce definite and permanent effects: habit, use, and disuse are potent in their effects. Specific characters are more variable than generic, and varietal than either. Rudimentary organs and secondary sexual characters are highly variable. Species closely related of similar constitution and similarly influenced, present analogous variations, and frequently exhibit characters which can only be explained as reversions to those of their ancient progenitors—e.g. zebra-like stripes on horses, or wood-pigeon's markings on fantails, tumblers, &c.

*Difficulties and Objections*.—In four chapters all the miscellaneous objections raised against the theory between 1859 and the appearance of the latest edition are successively stated, weighed, discussed, and met, as well as the much more serious difficulties pointed out by Darwin himself. These latter are, (1) the definiteness of species and the rarity of transitional forms; (2) the enormous degree of modification in habits and structure assumed by the theory, and the seeming improbability that Natural Selection should produce on the one hand an organ of such trifling importance as the tail of a giraffe, and on the other, an organ so wonderful as the eye; (3) the acquirement and modification through Natural Selection of such marvellous instincts as those of the bee; (4) the sterility of crossed species, and the fertility of crossed varieties. For these discussions, however, the reader must consult the work itself.

*Imperfection of the Geological Record*.—On the assumption of the extermination of an enormous number of intermediate varieties, which were the links between existing and remote ancestral forms—why, then, is not every geological formation charged with such links? Why does not every collection of fossils afford plain evidence of the gradation and mutation of the forms of life? Geology, assuredly, does not reveal any such finely graduated organic chain, and this is one of the most obvious and plausible objections to the

theory. The explanation offered is the extreme—the almost incredible—imperfection of the geological record. Only a small portion of the globe has been geologically explored with care; only certain classes of beings have been fossilised; and the number, both of specimens and species yet discovered, is absolutely as nothing compared with the number which must have passed away during even a single formation. The Malay Archipelago equals in area the formations best known to us; its present condition represents that of Europe while Europe's strata were being deposited; its fauna and flora are among the richest on the globe, yet, even if all the species were to be collected which ever lived there, how imperfectly would they represent the natural history of the world! Only few species are preserved at all, and most of these in an imperfect manner; moreover, subsidence being almost necessary for the accumulation of rich deposits, great intervals of time must have elapsed between successive formations, so that during periods of elevation, when variation would be most frequent, the record is least perfect. Moreover, geological formations have not been continuously deposited; the duration of specific forms probably exceeds that of each formation; migrations have largely taken place; widely ranging species are most variable, and oftenest give rise to new species; varieties have been at first local; and finally, it is probable that periods of modification are short as compared with periods of permanence. Hence we cannot find innumerable varieties, and any linking variety between two forms is, of course, ranked as a distinct species, for the whole chain cannot be permanently restored. Thus the geological record is a history of the world indeed, but one imperfectly kept, and written in a changing dialect; of this history we possess the last volume only, relating to two or three countries. Even of this volume only here and there has a short chapter been preserved, and of each page only here and there a few lines.

*Geological Succession of Organic Beings (Distribution in Time).*—The preceding difficulties excepted, the facts of palæontology agree admirably with the theory. New species come in slowly and successively; they change in different rates and degrees; old forms pass through rarity to extinction, and never reappear; dominant forms spread and vary, their descendants displacing the inferior groups, so that after long intervals of time the productions of the world appear to have changed simultaneously. The most ancient forms differ most widely from those now living, yet frequently present characters intermediate between groups now widely divergent, and they resemble to a remarkable extent the embryos of the more recent and more highly specialised animals belonging to the same classes. These laws, and, above all, the important law of the succession of the same types within the same areas during the later geological periods, and most notably between the Tertiary period and the present time (e.g. fossil and recent marsupials in Australia, and edentates in South America), cease to be mysterious, and become at once thoroughly intelligible on the principle of inheritance, and on that alone.

[Since the publication of the *Origin of Species* in 1859, palæontological research has been constantly furnishing the most triumphant verification of these views. The imperfection of the geological record was so far from overestimated that Huxley (*Science and Culture*, 1880), in comparing our knowledge at that time of the mammalian Tertiary fauna with that of 1859, stated that the results of the investigations of Gaudry, Marsh, and Filhol are 'as if zoologists were to become acquainted with a country hitherto unknown, as rich in novel forms of life as Brazil or South Africa once were to

Europeans.' Gaudry found the intermediate stages by which civets passed into hyenas; Filhol discovered still more remote ancestral carnivores; while Marsh obtained a complete series of forms intermediate between that, in some respects, most anomalous of mammals, the horse, and the simplest five-toed ungulates (see MAMMALS). Again, Darwin's belief that the distinctness of birds from all other vertebrates was to be accounted for by the extinction of a long line of progenitors connecting them with reptiles, was in 1859 a mere assumption; but in 1862 the long-tailed and intensely reptilian bird *Archæopteryx* (q.v.) was discovered, while in 1875 the researches of Marsh brought to light certain Cretaceous birds, one (*Hesperornis*) with teeth set in a groove, the other (*Ichthyornis*) with teeth in sockets, and with bi-concave vertebræ. Besides these reptilian birds, bird-like reptiles have similarly been forthcoming, and the hypothesis of Darwin is thus admirably verified. Considerable light, too, has been thrown on the pedigree of crocodiles; ammonites, trilobites, and other invertebrates have been arranged in series, while important collateral evidence is also furnished by 'persistent types' such as *Ceratodus*, *Beryx*, *Nautilus*, *Lingula*, &c., which have survived—we must assume by ordinary generation—almost completely unchanged since remote geological periods. On such grounds, therefore, Huxley asserted (*op. cit.*) that 'on the evidence of palæontology, the evolution of many existing forms of animal life from their predecessors is no longer an hypothesis, but an historical fact; it is only the nature of the physiological factors which is still open to discussion.'

*Geographical Distribution.*—Neither the similarity nor the dissimilarity of the inhabitants of various regions, whether of land or sea, can be accounted for by identity or differences of climate, or other physical conditions, but both are related in the most striking degree to the absence or presence of barriers to migration between those regions. Within the same area there exists the most marked affinity among the species, though these differ from place to place. Species appear to have arisen in separate definite centres, the few apparent exceptions being accounted for by migration and dispersal, followed by climatic and geographical changes. But for a summary of our knowledge of the existing mode of distribution of organic life, and of the way in which that distribution has been effected, as well as of the very important bearing of these facts upon the theory of evolution, which they may be said, indeed, more than any other class of facts, to have suggested, see the article GEOGRAPHICAL DISTRIBUTION.

*Morphological Arguments.*—The physiological and distributional lines of argument being summarised, those furnished by morphology, although not less numerous and highly important, can only be very briefly outlined. These are mainly four, and are derived from (a) Classification, (b) Homologies, (c) Embryology, (d) Rudimentary Organs.

(a) *Classification.*—Naturalists arrange the species, genera, and families in each class, on what is called the Natural System. But what is meant by this system? Is it, after all, merely an artificial scheme for enunciating general propositions, and of placing together the forms most like each other? or does it, as many believe, reveal the plan of creation? The grand fact of classification is, that organic beings, throughout all time, are arranged in groups subordinated under other groups—individuals under varieties, and these again under species; species under genera; genera under sub-families, families, and orders; and all under a few grand classes. The nature of all these relationships—the rules followed and the difficulties met

by naturalists in their classifications—the high value set upon constant and prevalent structures, whether these be of great or little use, or, as with rudimentary organs, of none at all—the wide opposition in value between such misleading resemblances of adaptation, as, for instance, the fish-like form of whales, and such characters of true affinity as are afforded by the structure of their circulatory or respiratory system—all these receive a simple and natural explanation on the view of the common descent of allied forms with modification through variation and natural selection; while it is to be noted that no other explanation has ever even been attempted. The element of descent, too, is already used in linking all the sexes, ages, forms, and varieties of the same species, widely though these (e.g. Cirripedes) may differ from each other in structure: and we have only to extend it to understand the meaning and origin of the Natural System.

(b) *Homology*.—The members of the same class, independently of their habits of life, resemble each other in their general plan of organisation. Thus, the hand of man, the digging-paw of the mole, the leg of the horse, the paddle of the porpoise, and the wing of the bat, are all constructed on the same pattern, bone corresponding to bone. Similarly with the hind-limb. Again, the mouths of insects are of innumerable varieties of form and use—witness the long spiral trunk of a moth, and the great jaws of a beetle—yet these are formed by modifications of an upper lip, mandibles, and two pairs of maxillæ. And so it is with the limbs of crustaceans, or the flowers of plants; in fact, with the organs of every class of beings.

This *conformity to type* is ‘powerfully suggestive of true relationship, of inheritance from a common ancestor;’ it admits, in short, as no one indeed denies, of a simple explanation in terms of the evolutionary theory, and thus strengthens that theory not a little. Attempts have been made to explain this unity of plan in two other ways—first, by assuming it due to utility, which is negatived by the facts, since organs of identical use (e.g. the wings of a bird and those of a butterfly) very frequently do not conform to the same type at all; secondly, by attributing it to a unity of design, which, however, (a) instead of being always maintained, as it should be, on the theory, is not unfrequently quite lost in highly specialised forms; and which, even if it always existed, (b) would directly suggest the unity of descent, the design thus serving only to mislead the anatomist.

*Serial Homology*, too, has to be accounted for—that unity of type which is found on comparing the different parts and organs in the same individual, so that the wonderfully complex and varied jaws and legs of a lobster, or the widely different leaves, sepals, petals, stamens, and pistils of a flower, are all found to be modifications of a simple limb, and a simple leaf-organ respectively. Not only are such metamorphoses apparent on comparison, but they can be actually observed to occur during the development of each individual; is then the term metamorphosis to have a mere metaphorical meaning when applied to the species, or has it not actually arisen in past time, through the natural selection and transmission of advantageous variations?

(c) *Development*.—It has been already indicated that the serially homologous parts in the same individual are alike during an early embryonic period, as also are the homologous organs in animals which, like bat, horse, and porpoise, may be widely differentiated in adult life. So closely, too, do the embryos of the most distinct species belonging to the same class resemble each other, that even Von Baer was unable to distinguish whether two un-

labelled specimens were lizards, birds, or mammals. This law of embryonic resemblance holds very widely—e.g. with young crustaceans. The embryo often retains within the egg or womb structures which are of no service to it, either at that or at a later period of life, like the transitory gill-arches of birds or mammals; while, on the other hand, larvæ (e.g. of insects), which have to provide for their own wants, undergo complete secondary adaptation to the surrounding conditions. The process of development goes from the general to the special; thus there is generally an advance in organisation. In peculiar conditions, however, degeneration may occur. All these facts are readily explained on the principle of successive slight variations not necessarily or generally supervening very early in life, and inherited at a corresponding period; hence it is in the highest degree probable that most embryonic stages show us more or less completely the progenitor of the group in its adult state; and embryology thus rises greatly in interest. See EMBRYOLOGY.

(d) *Rudimentary Organs*.—Rudimentary, atrophied, and abortive organs, bearing the plain stamp of intility, are so extremely common that it is impossible to name a higher animal in which none occurs. The mammae of male mammals, the hind-legs of boas, the wings of many birds, or the teeth of foetal whales, and the upper incisors of unborn calves, are familiar instances. Such organs are intelligible on the evolutionary theory, and on that theory alone.

*Recapitulation and Conclusion*.—After tersely summing up the preceding mass of evidence, Darwin concludes by pointing out (a) that the theory of evolution by natural selection is no more inimical to religion than is that of gravitation, to which the same objection was strongly raised; (b) its revolutionary influence on the study of all departments of natural history; (c) on Psychology (q.v.); (d) on the origin of man and his history (see MAN); (e) on our theories of future progress.

*Envoy*.—‘It is interesting to contemplate a tangled bank clothed with many plants of many kinds, with birds singing on the bushes, with various insects flitting about, and with worms crawling through the damp earth, and to reflect that these elaborately constructed forms, so different from each other, and dependent on each other in so complex a manner, have all been produced by laws acting around us. These laws, taken in the largest sense, being Growth with Reproduction; and Inheritance, which is almost implied by reproduction; Variability from the indirect and direct action of the conditions of life, and from use and disuse; a Ratio of Increase so high as to lead to a Struggle for Life, and as a consequence to Natural Selection, entailing Divergence of Character and the Extinction of less improved forms. Thus, from the war of nature, from famine and death, the most exalted object which we are capable of conceiving, namely, the production of the higher animals, directly follows. There is grandeur in this view of life, with its several powers, having been originally breathed by the Creator into a few forms, or into one; and that, whilst this planet has gone cycling on according to the fixed law of gravity, from so simple a beginning endless forms most beautiful and most wonderful have been, and are being, evolved.’

The stormy reception of the *Origin of Species*, the controversies to which it gave rise, its rapid and widespread acceptance, helped as it was by the independent support, yet generous self-abnegation, of Dr Wallace, and the powerful advocacy of Huxley, Hooker, Asa Gray, and others, are all recorded in Darwin's Life. Of the proposed expansion of the *Origin*, only the first chapter actually

appeared, as *Variation of Animals and Plants under Domestication* (see VARIATION); but in *Fertilisation of Orchids, Forms of Flowers, Insectivorous Plants, Climbing Plants, Movement in Plants*, we have a series which not only greatly developed Darwin's favourite study of adaptations, and with it enormously strengthened his general theory, but gave to the arid field of botany the interest and freshness of a new intellectual spring (see BOTANY). Again, the very difficulties which he felt to be presented to his theory by the complex phenomena of bee and ant society led him onwards, till he reached the problems of mind and language; the obvious and burning question of the origin of man had also to be faced, and thus we had the *Descent of Man* and the *Expression of the Emotions*.

Before conclusion, justice demands, if not discussion, at least mention of some of the more important criticisms which have been urged against Darwin's theory. That which Darwin himself seems to have felt as most serious was made by Fleeming Jenkin, who laid stress on the tendency to swamping any individual variation, however advantageous, through intercrossing. Mivart's *Genesis of Species* next engaged him most; but Darwin's replies to these and other criticisms up to 1872 will be found in the final edition of the *Origin of Species*. In his essay in Darwin's *Life*, Huxley says: 'I venture to affirm that so far as all my knowledge goes, all the ingenuity and all the learning of hostile critics have not enabled them to adduce a single fact of which it can be said this is irreconcilable with the Darwinian theory;' while Sir Ray Lankester assures us that 'since its first publication in 1859 the history of Darwin's theory has been one of continuous and decisive conquest, so that at the present day it is universally accepted as the central, all-embracing doctrine of zoological and botanical science.'

As a matter of fact, however, this 'universal acceptance' is not without its universally distributed exceptions. Some of Darwin's contemporaries withheld their adhesion—e.g. Virchow in Germany, Owen and Cleland in Britain, and the older French naturalists; nor can the critical and controversial writings of Mivart, the Duke of Argyll, Samuel Butler, and others, be thus wholly ignored. Constructive criticism is also busy. On one hand certainly we have the ultra-Darwinian speculations of Weismann, warmly accepted by Lankester and others; but on the other, attempts are again being made, and with increasing frequency, to restate the theory of evolution more or less completely in non-Darwinian terms. Thus, following up the doubt which occasionally troubled Darwin's later years, that he had assigned too little importance to the modifying factors of use and disuse, of environment, &c., we have Herbert Spencer re-entering the field; in America an active Neo-Lamarckian school has also arisen, which lacks neither knowledge nor thoughtfulness; in Germany we owe new constructive efforts to Nageli and Semper, and more recently to Eimer (1890) and Plate (1908); while in Britain complementary hypotheses have been propounded by Romanes, Sutton, Gulick, Geddes, &c. But such proposed positive contributions to the evolutionary theory fall rather to be treated under EVOLUTION.

See BIOLOGY, BOTANY, EVOLUTION, ENVIRONMENT, HEREDITY, GEOGRAPHICAL DISTRIBUTION, ZOOLOGY, and other articles. Besides the works of Darwin himself, and those of Alfred Russel Wallace (from *Natural Selection* in 1870 to *Darwinism* in 1889), with the special treatises referred to under the above-mentioned and minor articles (e.g. FERTILISATION), see F. Darwin's *Life of Charles Darwin*; A. C. Seward (ed.), *Darwin and Modern Science* (1909); American Assoc. Adv. of

Science, *Fifty Years of Darwinism* (1909); Haeckel's *Generelle Morphologie and Natural History of Creation*; Huxley's *Lay Sermons, American Addresses, Science and Culture, Anatomy of Invertebrated Animals*; also his essay *On the Reception of the Origin of Species in Darwin's Life*, vol. II.; 'Obituary Notice of Charles Darwin' in *Proc. Roy. Soc.* (Lond 1888); and 'Struggle for Existence, a Programme' (*Nineteenth Century*, 1888). Weismann's *Studies in the Theory of Descent* (1880-82), and for later developments his subsequent papers (see HEREDITY and WEISMANN), must also be noted. Romanes's *Scientific Evidence of Organic Evolution*, Lankester's *Degeneration* (both 'Nature' series), Schmidt's *Doctrine of Descent and Darwinism*, Fiske's *Darwinism and other Essays*; Eimer, *Organic Evolution* (1890); T. H. Morgan, *Evolution and Adaptation* (1903); Kellogg, *Darwinism To-day* (1907); Thomson, *Darwinism and Human Life* (1909).

Of controversial writings may be cited Mivart's *Genesis of Species, Lessons from Nature*, &c.; the Duke of Argyll's *Unity of Nature*, as well as the review articles of both writers. See also Butler's *Evolution, Old and New*, and *Luck or Cunning*. For the literature of the more constructive attempts referred to, see EVOLUTION. For general bibliography Bettany's *Life of Darwin* is most accessible; also Seidlitz, *Die Darw. Theorie* (Leip. 1875); Romanes, *Darwin and after Darwin* (3 vols 1892-97); Osborn, *From the Greeks to Darwin* (1895); Poulton, *Darwin and Natural Selection* (1896).

**Darwin Sound** and **MOUNT DARWIN** are on the SW. side of King Charles's South Land, Tierra del Fuego. The mountain rises 6800 feet.

**Dasent**, SIR GEORGE WEBBE, was born in 1820 at St Vincent in the West Indies, of which island his father was attorney-general. He was educated at Westminster School and King's College, London; graduated B.A. at Magdalen College, Oxford, in 1840; and was called to the bar at the Middle Temple in 1852, in which year also he received his degree of D.C.L. He was for twenty-five years (1845-70) an assistant editor of the *Times*, and married a sister of its editor, Mr Delane (q.v.). An accomplished linguist, especially in Scandinavian, he acted as examiner in English and modern languages for the Civil Service; he was a Civil Service Commissioner in 1872-92, was knighted in 1876, and died 11th June 1896. In 1842 he published a translation of *The Prose or Younger Edda*; which was followed by an essay, 'The Naismen,' in the *Oxford Essays* (1858); *Popular Tales from the Norse, with an Introductory Essay on the Origin and Diffusion of Popular Tales* (1859), and *Tales from the Efield* (1874), both from the Norwegian of Asbjørnsen; translations from the Icelandic of the *Saga of Burnt Njal* (1861), and the *Story of Gisle, the Outlaw* (1866); and an Introduction and Life of Cleasby, prefixed to Vigfusson's completion of Cleasby's unfinished *Icelandic-English Dictionary* (1874). Sir George Dasent also wrote several fair novels. His famous introduction to Asbjørnsen's *Popular Tales* was a solid contribution to folklore, being an admirable exposition of the Aryan theory of story-transmission as advocated by Grimm and Max Muller.

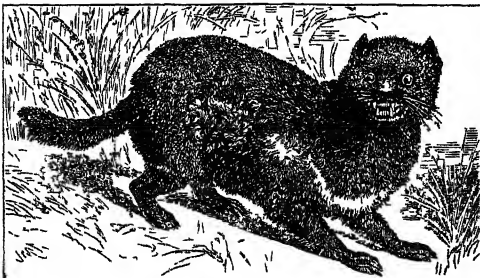

**Dash**, COUNTESS, the name under which Gabrielle Anna Cisterne de Courtiras, Vicomtesse de Saint-Mars, published a series of novels, many of which were readable, if of but slender literary merit. She was born at Poitiers, August 2, 1804, of a noble family, married early, and took to literature for a living after the loss of her property, writing sometimes as many as five or six novels a year. She died 11th September 1872. Her stories deal almost exclusively with the aristocratic world and its more or less illegitimate liaisons. They have a certain brightness and vigour, but lack reality, and are peopled by a crowd of stilted puppets rather than living men and women. Of her numberless books may only be mentioned

*Les Amours de Bussy-Rabutin* (1850), *La Pomme d'Eve* (1853), *Les Galanteries de la Cour de Louis XV.* (1861), *Comment Tombent les Femmes* (1867), and *Les Aventures d'une Jeune Mariée* (1870).

**Dashkoff**, PRINCESS EKATERINA ROMANOVNA, daughter of Count Voionzoff, was born 28th March 1743, at St Petersburg, and from her earliest youth received a careful training. She married Prince Dashkoff when only fifteen years old, but was left a widow three years after. She was an intimate friend of the Empress Catharine II., and one of the heads of the conspiracy formed against Peter III., the success of which secured the throne to Catharine. Soon afterwards quarrelling with Catharine, she obtained permission to travel, and visited Germany, England, France, and Italy, making the acquaintance of many eminent men (among others, Garrick, Dr Blair, and Dr Robertson). The empress and she were reconciled to each other, and the princess was appointed Director of the Academy of Arts and Sciences; and in 1783, President of the Russian Academy, established at her own suggestion in imitation of the French Académie. On the death of Catharine in 1796, she was deprived of her offices, and ordered by Paul III. to retire to her estates at Novgorod. She died 16th January 1810. Besides writing several comedies and occasional papers, the Princess Dashkoff was mainly instrumental in inducing the Russian Academy to draw up a dictionary of the Russian language, and herself executed part of the work. See her very interesting autobiography (trans. 1840).

**Dasyprocta.** See AGOUTI.

**Dasyures** (*Dasyuridae*), a family of carnivorous marsupials, including forms which in the Australian and Tasmanian fauna take the place filled in other regions by carnivores. The large sharp canines, the sharp-pointed cusps on the back teeth, and the clawed toes are among the adaptive carnivorous features, and there are others of a more technical nature. The dasyures are nocturnal and savage animals, and, as one would expect, peculiarly untamable. One of the most pronounced is the Tasmanian Devil (*Sarcophilus ursinus*), a savage animal, about the size of a badger, with a disproportionately large and broad head, and massive crowded teeth. The body is plump; the fur is coarse and brownish-black, with a white band on the chest, and another at the end of the back; the tail is

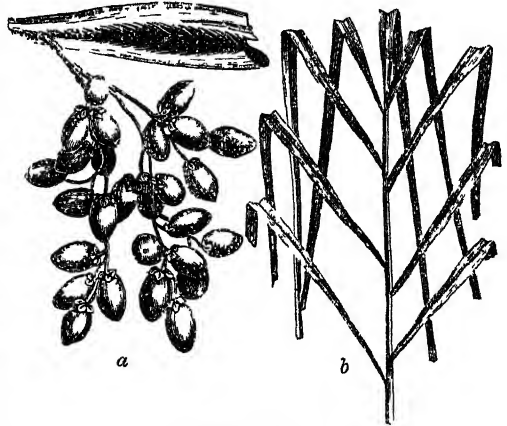

Tasmanian Devil (*Sarcophilus ursinus*).

thick, and about half as long as the body. In Tasmania these 'devils' used to commit great havoc among poultry and even sheep, but are being driven into more and more remote haunts. The Spotted Dasyure (*Dasyurus maculatus*), also Tasmanian, is a much smaller animal, about the size of a cat. Another 'wild cat' of the same country and Victoria is Mauge's Dasyure (*D. maugei* or *viverrinus*). Other species occur in Australia and New Guinea. Also included in the dasyures are

two genera, *Thylacinus* and *Phascologale* (q.v.). The former, the Thylacine (q.v.) or Tasmanian wolf, is the largest carnivorous marsupial; the latter is insectivorous. See MARSUPIAL.

**Date.** See CHRONOLOGY.

**Date Palm** (*Phoenix*), a genus of palms, the most important species of which is the Common Date Palm, the *Palm Tree* of Scripture (*P. dactylifera*), a native of the northern half of Africa, the south-west of Asia, and some parts of India, and of which the cultivation is no less wide, and still extending.

Date Palm :

a, bunch of dates dependent from their spathe; b, portion of leaf.

Some parts of China produce large crops. The stem, which is straight and simple, reaches a height of 30 to 60 feet, and bears a head of 40 to 80 glaucous pinnated leaves, of 8 to 10 feet long, and a number of branching spadices, each of which on the female tree bears 180 to 200 fruits (dates, *dactyli*). A bunch of dates weighs 20 or 25 lb., so that an average year's crop may be reckoned at 300 to 600 lb. per tree, and the yield per acre at about twelve times that of corn. From the earliest times fertilisation has been artificially aided by cutting off the male inflorescences just before the stamens ripen, and suspending them among those of the female tree; so avoiding the risks and losses of ordinary wind-fertilisation. In a palm grove there may be but one male stem to forty or fifty fruit-bearing ones. The Arabs seldom raise palms from seed; to make sure of the sex they take suckers from female trees known to bear good fruit. The tree begins to bear about the eighth year, reaches maturity at about thirty years, and does not decline until about the age of one hundred. This is one of the most important and useful of all the palms. In Egypt, and generally in North Africa, Persia, and Arabia, dates form the principal food, and date palms the principal wealth of the people. The fleshy part of the fruit contains 58 per cent. of sugar, accompanied by pectin, gum, &c. The fruit is eaten either fresh or dried, and in the latter state becomes an article of commerce. Cakes of dates pounded and kneaded together, and so solid as to be cut with a hatchet, are the store of food provided for African caravans on their journey through the Sahara. A sweet juice (date-honey) can be expressed from the fruits, from which a kind of wine is obtained by fermentation; also a sort of vinegar; an ardent spirit is of course also distilled from the fermented juice. Palm-wine is also made from the sap after the terminal bud is removed. The bud is eaten as palm-cabbage, similarly also the undeveloped panicles of flowers. The date

'stones' or seeds are roasted in North Africa as a substitute for coffee, and have also been introduced into Britain for the same purpose. They are also ground and pressed for oil, and the residue used for feeding cattle. From leaf-stalks of the common date palm, all kinds of basket and wicker work are also made, and walking-sticks, fans, &c. The leaves themselves are made into bags, mats, &c.; the fibres of the web-like integuments at the base of their stalks into cordage. The wood is used for building, fences, &c.—The Toddy Palm of the north of India, or Wild Date Palm (*P. sylvestris*), so nearly resembles this species, that it is doubtful if it is distinct. In some places, the trees present a curiously distorted and zigzag appearance, from the practice of yearly tapping the alternate sides for the sap or *toddy*. This forms a grateful and wholesome beverage; readily also fermenting into palm-wine, and by distillation yielding *Arrack* (q.v.); whilst if boiled down it yields the syrup called *jaggery*, from 4 lb. of which 1 lb. of sugar is obtained, a single tree producing about 7 or 8 lb. of sugar annually. The operation of tapping for toddy spoils the fruit of the tree, which is small and much inferior to the African date. It is, however, eaten.—Another species, *P. paludosa*, the most gregarious of Indian palms, growing only 6 or 8 feet high, covers the landscape of the Sunderbunds with the liveliest verdure. *P. aculeis* and *P. farinifera* are also dwarf and closely allied common Indian species. *P. reclinata* is a characteristic palm of the Natal coast, and *P. spinosa* of Sierra Leone, &c. Some derive the origin of the colonnade pillar in architecture to the regular mode of its planting and the use of its stem in building, while in symbolic interest it stands second to no other plant. The symbol of beauty and of victory alike to Hebrews and Hellenes from the earliest times, it passed readily to the suggestion of victory over death and glorious immortality; hence alike the name *Phoenix* from the fabled bird, and the habit of representing angels and the blessed with palms in their hands. It was largely used also for decoration of festivals, and for strewing in processions. Christ's triumphal entry into Jerusalem is still commemorated on Palm Sunday (q.v.).

**Date Plum** (*Diospyros*), a genus of Ebenaceæ, important for timber (see EBONY, IRONWOOD) and fruit. The Common Date Plum or Fishamin, also called the European Lotus and the Date of Trebizond (*D. lotus*), is a tree of 18 to 30 feet in height, with oblong shining leaves and small reddish-white flowers, a native of the coasts of the Caspian Sea, Northern Africa, &c., but cultivated and naturalised in the south of Europe. It can also be grown in the south of England. Its fruit is yellow, sweet, and astringent. It is eaten when over-ripe, like the medlar, or is used for preserves. The Virginian Date Plum, or Persimmon (*D. virginiana*), is a tree of 30 to 60 feet high, with ovate oblong leaves and pale-yellow flowers, a native of the southern states of North America, where one tree often yields several bushels of fruit. The fruit is about one inch in diameter, with six to eight oval seeds. It is not palatable till mellowed by frost, and is sweet and astringent. A kind of beer or cider and an ardent spirit are made from it. *D. Mabola* is cultivated as a fruit-tree in Mauritius. *D. Kaki*, sometimes called the Keg-fig, is a native of Japan, which occasionally is kept in greenhouses in France and England. The sweetmeat called *Figues-caques* is made from this fruit in France. The fruit of some other species is also edible—e.g. *D. decandra* of Cochin-China.

**Datia**, a native state of Bundelkhand, with a pop. of 174,000. The chief town, Datia (pop. 25,000), 125 miles SE. of Agra, on a rocky eminence, has several palaces, some now untenanted.

**Datiaceæ**, a very small order allied to Begoniaceæ, including only four species, of remote distribution. *Datisca cannabina*, a plant much resembling hemp, is cultivated in Crete and Asia Minor for its hemp-like fibre, also as a source of yellow dyestuff. It has tonic properties.

**Dative**. See DECLENSION.

**Dato**, EDUARDO, born at Coruña in 1856, studied law at Madrid, was alcalde of Madrid and several times Conservative prime-minister of Spain. He was assassinated in 1921.

**Datolite**, or DATHOLITE, a mineral, colourless or inclining to grayish, greenish, white, or yellowish-gray colour, occurring both massive and crystallised in rhombic prisms, the edges and angles of which are commonly replaced by planes. It is composed of boracic acid, silica, and lime, with a little water. It occurs generally in basic igneous rocks, as at Salisbury Crags, Edinburgh, and occasionally in schistose rocks.

**Datura, Daturine**. See THORN APPLE, ATROPINE.

**Daub**, KARL, a speculative theologian, was born 20th March 1765, at Cassel, studied philosophy and theology at Marburg, and became in 1795 professor of Theology at Heidelberg, where he died 22d November 1836. An earnest and singularly open-minded seeker after truth, although defective in the true historical sense, and not a robust and independent thinker, Daub laboured incessantly to find a sound basis for a reconciliation between religion and philosophy, and his successive writings reflect the whole development of prevailing philosophy from Kant to Hegel. Thus his *Lehrbuch der Katechetik* (1801) rests completely on Kant's fundamental principles; again, dominated by the influence of Schelling's 'philosophy of identity' are his *Theologumena* (1806) and *Einleitung* to Christian dogmatics (1810); while Schelling's transition to theosophy and to 'positive philosophy' is mirrored in Daub's *Judas Ischarioth* (1816), despite its eccentricities his best work. Hegel was called to Heidelberg in 1816, and henceforth it was his influence which was dominant over the receptive mind of Daub. In his *Dogmatische Theologie* (1833) and *Prolegomena* (1835), he attempts in the darkest language of the Hegelian dialectic a philosophical restoration of the dogmas of the church. Daub's *Theol. philos. Vorlesungen* were collected by Marheineke and Dittenberger in seven volumes (1838-43). See Rosenkranz's eulogistic but uncritical *Erinnerungen* (1837), and D. F. Strauss, *Charakteristiken und Kritiken* (2d ed. 1844).

**Daubenton**, LOUIS JEAN MARIE, naturalist, was born at Montbar in Burgundy, 29th May 1716. He studied theology at the Sorbonne, but soon gave himself up to medicine and anatomy. In 1742 his old schoolfellow, Buffon, invited him to assist him in the preparation of his great work on Natural History, and Daubenton contributed richly to the first fifteen volumes of the *Histoire Naturelle*, until the jealousy of Buffon led to an estrangement. Daubenton now devoted himself almost entirely to his duties in the Jardin du Roi, where he was professor of Mineralogy. He was also for a time professor of Natural History in the College of Medicine. He contributed largely to the first *Encyclopédie*, and wrote many valuable *mémoires*. He died 31st December 1799.

**Daubeny**, CHARLES GILES BRIDLE, chemist and botanist, was born at Stratton in Gloucestershire, 11th February 1795. He devoted himself chiefly to the elucidation of natural phenomena by the aid of chemical science—his great work being *A Description of Active and Extinct Volcanoes* (1826). He also wrote on thermal springs. He

became professor of Chemistry at Oxford in 1822, of Botany in 1834, and was an F.R.S. Other works are an *Introduction to the Atomic Theory* (1831), *Lectures on Agriculture* (1841), and *Lectures on Climate* (1862). Daubeny died December 13, 1867.

**D'Aubigné, JEAN-HENRI MERLE**, a popular ecclesiastical historian, was born at Eaux-Vives, near Geneva in Switzerland, 16th August 1794, studied there and at Berlin—under Neander—and in 1818 became pastor of the French Protestant Church in Hamburg. In 1823 he was appointed court-preacher at Brussels; but after the revolution of 1830, he declined the post of tutor to the Prince of Orange, and returning to Geneva, took part in the institution of the new evangelical church, and filled the chair of Church History in its theological seminary until his sudden death, in the night of October 20-1, 1872. With the exception of some visits to England and Scotland, where he had numerous readers and admirers, and where he received the degree of D.C.L. from Oxford and the freedom of the city of Edinburgh, he remained constantly at Geneva. The work which has given him a widespread reputation is his *Histoire de la Réformation au Sixième Siècle* (1835-53); it has been translated into most European tongues, and has attracted more notice abroad than at home; it is written with a devout, fervid sympathy that is often eloquent, although the narrative is too graphic to be everywhere exact. Its popularity has been immense. Among his other writings are *Germany, England, and Scotland* (Lond. 1848); a vindication of Cromwell (1848); *Trois Siècles de Lutte en Écosse* (1849); and *Histoire de la Réformation en Europe au Temps de Calvin* (1862-78).

**D'Aubigné, THÉODORE AGRIPPA**, a famous French scholar, was born on 8th February 1550, near Pons in Saintonge. At an early period he exhibited a remarkable talent for the acquisition of languages. Although born of a noble family, he inherited no wealth from his father, and consequently chose the military profession. In 1567 he distinguished himself by his services to the Huguenot cause, and was subsequently rewarded by Henry IV., who made him vice-admiral of Guienne and Brittany. His severe and inflexible character frequently embroiled him with the court; and after Henry's assassination (1610), he betook himself to Geneva, where he spent the remainder of his life in literary studies. He died April 29, 1630, leaving a worthless son, Constant, who was father of Madame de Maintenon. D'Aubigné's best-known work is his *Histoire Universelle, 1550-1601* (Amsterdam, 1616-20), which had the honour of being burned in France by the common hangman. D'Aubigné was possessed of a spirit of biting satire, as is proved by his *Confession Catholique du Sieur de Sancy*, and his *Aventures du Baron de Fenesté*. See his *Histoire Secrète, écrite par lui-même* (1731); French studies by Réaume (1883) and Morillot (1884), German by Winckler (1906).

**Daubigny, CHARLES FRANÇOIS**, landscape-painter and etcher, born in Paris in 1817, studied under his father, who was a miniature-painter, Paul Delaroche, and others, and from 1838 exhibited in the Salon, although his full recognition came only after the artist had reached his fiftieth year. He devoted himself to close and sympathetic study from nature, working much on the Seine in a house-boat, and developed a style of landscape art marked by singularly unaffected fidelity and originality. In 1853 he gained a first-class medal with his 'Pool of Gylion.' In 1857 he produced his 'Spring-time;' in 1861, 'The Banks of the Oise;' in 1872, 'Windmills at Dordrecht;' and in 1877, his large and very impressive 'Rising Moon.' His 'Sluices in the Valley of Optevos' (1855) and his 'Vintage'

(1863) are in the Luxembourg Gallery. He is also known as a book-illustrator and as a vigorous etcher, having produced over a hundred plates, some reproductions, others direct from nature, marked by great frankness of method and free painter-like quality. He died in Paris, 19th February 1878.

**D'Aubusson, PIERRE**, Grand-master of the order of St John of Jerusalem, surnamed 'the Shield of the Church,' was born of a noble French family in 1423. At an early age he entered the service of the Emperor Sigismund, and served under the Archduke Albrecht of Austria against the Turks. Returning to France, he served with the Armagnacs against the Swiss, and covered himself with glory at their defeat near St Jacob (1444). He next joined the order of the Knights of Rhodes, and rose rapidly into power, becoming grand-master in 1476. He laboured to bring about a confederation of all the Christian powers to counteract the triumph of the Turks that followed the fall of Constantinople. Mohammed II.'s career of conquest, which threatened to spread over Western Europe, was stayed alone by the obstinate bravery of D'Aubusson and his little colony of Christian soldiers in the island of Rhodes. In May 1480 an army of 100,000 Turks invested the town, but were forced to raise the siege after a month's desperate fighting, leaving behind them as many as 9000 dead. Mohammed was filled with fury, and a second attack was only averted by his death in 1481. D'Aubusson died in 1503. See HOSPITALIERS.

**Daudet, ALPHONSE**, was born at Nîmes on May 13, 1840. His family had been in trade, but were not in good circumstances. He was, however, well educated at the Lyons Lycée, and was able when quite a boy to take the place of usher in a school at Alais, an employment of which, in *Le Petit Chose* and others of his works, he has given no cheerful reminiscences. He was only seventeen when, giving up his ushership, he set out for Paris after his elder brother, Ernest, who himself became a journalist and novelist of some mark. Alphonse (as also did Ernest) obtained an appointment as clerk or private secretary in the office of the Duc de Morny, of whom he has drawn a famous portrait in *Le Nabab*. Indeed, one of the main characteristics of Daudet's method, and one of the main reasons of his popularity with some, and his unpopularity with other readers, is the manner in which he seems to have utilised almost every circumstance and almost every acquaintanceship of his life in his books. Daudet's literary efforts, however, began with poetry; and his first book, in 1858, was entitled *Les Amoureuses*. He also devoted some not too successful years of experiment to theatrical work, writing by himself, or with a collaborator, *La Dernière Idole* (1862), *L'Éillet Blanc* (1865), *Le Frère Aîné* (1868), *Le Sacrifice* (1869), *Lise Tavernier*, and *L'Arlésienne* (1872), pieces of which the earlier were more successful than the later. Besides this, he contributed to many journals, especially the *Figaro*. In this form appeared some of his best work, the *Lettres de Mon Moulin* (collected 1869), *Robert Helmont* (1874), the *Contes du Lundi*, and others; and it was in these years that he conceived the charming extravaganza of *Tartarin de Tarascon*, a most amusing satire on the characteristics of the natives of the south of France (1872), which he followed up with *Tartarin sur les Alpes* (1886) and *Port Tarascon* (1890).

It was not, however, till many years after his literary beginnings that Daudet hit on the style which made him popular and famous. He had sketched something of the kind in 1868 in *Le Petit Chose*, a book full of pathos and of reminis-

cences of his own early struggles. This pathetic quality is still further developed in *Jack* (1876), the story of an illegitimate child, part of the interest of which turns on the half-malicious sketches of certain literary Bohemians; and in *Fromont Jeune et Risler Aîné* (1874), where the devotion of a man of business to his firm, his wife, and his brother, meets in all three cases with an equally evil return. These were followed by *Le Nabab* (1877), a transparent caricature of Moïny and other well-known personages under the empire; *Les Rois en Exil* (1879), the chief parts in which are supposed to have been played also by actual persons; *Numa Roumestan* (1881), the hero of which was supposed to have some resemblance to Gambetta, and which at any rate is as remarkable in the serious way as *Tartarin* in the comic amongst satires on the 'meridional' type; *L'Évangéliste* (1883), in which the then new craze of the Salvation Army was introduced; *Sapho* (1884), a book somewhat out of Daudet's usual line, in which the mutual infatuation of a young man and a courtesan and artist's model is drawn with remarkable if not very wholesome power; and *L'Immortel* (1888), in which all the author's powers of ridicule, and all his practised skill in attacking individuals under a thin disguise, are employed to throw discredit on the French Academy. The vigour, and within certain limits, the versatility, of this series of novels is not denied by any one; but in addition to the personality already noticed, there has been charged against the earlier ones at least a following of Dickens, which can hardly be accidental, though it has been asserted to be so.

Daudet married early a lady of talent, who rendered him much assistance in his literary work, and he formed for some time part of a coterie of remarkable literary characters, which included Turgénief, Gustave Flaubert, the brothers Goncourt, and Zola. He published autobiographical papers, collected as *Trente Ans de Paris* (1887), and *Souvenirs d'un Homme de Lettres* (1889). Long a sufferer from locomotor ataxy, he died 16th December 1897. See R. H. Sherard's *Daudet* (1894); Diederich's German study (1901); his brother Ernest's *Mon Frère et Moi* (1882); the Memoir by his son Léon (1898); Brunetière, *Le Roman Naturaliste*; Donnicié, *Portraits d'Écrivains*.—His wife, JULIA ALLARD, born in Paris in 1845, published several volumes of poetry and literary sketches, including *Reflets sur le Sable et sur l'Eau* (1903), *Au Bord des Terrasses* (1906), *Souvenirs autour d'un Groupe Littéraire* (1910), *Les Archipels Lumineux* (1913).—Their son, LÉON DAUDET, born in 1868, has written, besides the Memoir above mentioned, novels, *Souvenirs* (1914 et seq.), and much royalist and Germanophile journalism.

**Daudnagar**, a mean-looking town in the Gaya district of Bihar and Orissa, on the Son, 90 miles SW. of Patna. It possesses, however, a considerable river trade, and manufactures coarse fabrics both of wool and of cotton. Pop. 9000.

**Daugavpils**, the Lettish name of Dvinsk or Dinaburg (q.v.).

**Daulatabad** ('fortunate city'), a town and fort in the Deccan, within the Nizam's Dominions, 28 miles NW. of Hyderabad. The fortress consists of a conical rock, 600 feet high, with a wide ditch and an outer wall nearly 3 miles in circumference. The place surrendered to the Mohammedians in 1294, and Shah Muhammad Tughlak (1324-51) thrice attempted to remove the seat of government thither from Delhi. The fortress has not been garrisoned now for many years, and the town has greatly decayed.

**D'Aulnoy**. See AULNOY.

**D'Aumale**. See AUMALE, DUC D'.

**Daumer**, GEORG FRIEDRICH, an able but eccentric German writer, was born in 1800 at Nuremberg, where for a time he was a professor in the gymnasium, and where Kaspar Hauser (q.v.) was committed to his care. Abandoning the pietism of his student days, he passed through Schelling's philosophy to a position of bitter antagonism to Christianity, which he wished swept from the face of the earth; but in 1859 he joined the Ultramontane party, and became one of its foremost champions. His many philosophical writings reflect his varying positions; so late as 1847 he endeavoured to prove that among the ancient Jews and the Christians of the first century human sacrifice obtained; from 1859 he expounded and defended the faith. His poetical works, especially *Mahomet* (1848) and the *Liederbluten des Hafis*, two graceful imitations of Persian poetry, have gained a high reputation. Daumer died at Würzburg, 14th December 1875.

**Daumier**, HONORÉ (1808-79), a celebrated French caricaturist, was born at Marseilles. Fashion, tittle-tattle, scandal, politics, blenishes of figure, and oddities of character in turn inspired his inexhaustible genius for mockery. Few among his illustrious contemporaries escaped his pencil, and his caricatures had always some strikingly truthful feature about them. He made his début in the *Charivari*, in a series of sketches from *Robert Macaire*; and the revolution of 1848 suggested two of his most remarkable series—*Idylles Parlementaires* and *Les Représentants Représentés*. In old age Daumier became blind, and was befriended by Corot. See books by Alexandre (1888), Frantz and Uzanne (1904), Marcel (1906), and Sadleir (1925).

**Daun**, LEOPOLD JOSEPH, GRAF VON, commander-in-chief of the imperial troops during the Seven Years' War, was the son of Count Wierich Philipp von Daun, a distinguished officer in the Austrian service, and was born at Vienna, 24th September 1705. Entering his father's regiment, he acquired a reputation during the Turkish campaigns (1737-39). The war of the Austrian Succession also afforded him many opportunities of displaying that combination of valour and prudence for which he was famous. After the peace with Prussia in 1745, Daun fought against the French in the Netherlands (1746-48), and in 1754 received the dignity of field-marshal. Before this, he had, in spite of many obstacles, introduced into the imperial army a new military system, and reorganised the Military Academy at Vienna. At the commencement of the Seven Years' War he commanded the army of Moravia in 1757, and neutralised the defeat of the Austrians under General Browne near Prague, by driving Frederick the Great, who had beleaguered that city, as far as Kolin, and forcing him, after a hard-fought battle, to evacuate Bohemia. On the 14th of October 1758 he gained another victory over Frederick at Hochkirch, and came near to annihilating the Prussian army. In 1759, at Maxen, he compelled Fink, the Prussian general, with 11,000 men, to surrender. After this, however, he gained no important successes; Frederick began to understand the tactics of 'the Austrian Fabius Cunctator,' and to conduct his campaigns accordingly. Daun died 5th February 1766.

**Dauphin** (Lat. *Delphinus*), a title, perhaps originally a proper name, borne by the counts of Anvergne and by the sovereign lords of Vienne, who therefore bore a *dolphin* as their crest. The last of the latter, Humbert II., in 1343 bequeathed, and in 1349 sold, his possessions to Charles of Valois, grandson of Philippe VI. of France, on condition that the eldest son of the king of France should bear the title of Dauphin of Vienne, and govern the province. As late as the time of Louis

XI., the dauphin exercised almost sovereign rights; but after his time these were gradually abridged, until Dauphiné was placed under the same laws as the rest of the kingdom, and the title became merely honorary. After the revolution of 1830, it was abolished altogether. See DELPHIN CLASSICS.

**Dauphiné**, formerly a frontier province in the south-east of France, now forming the departments Drôme, Isère, and Hautes Alpes. Its capital was Grenoble, and it boasted its 'seven wonders'—remarkable caves, mountain-peaks, &c. Once the territory of the Allobrogi, after the fall of the Roman empire Dauphiné formed the southernmost part of the kingdom of Burgundy. It then passed under the dominion of the Franks, and after the dismemberment of the Carolingian monarchy, it became a portion of the new Burgundian kingdom of Arles. It then passed by legacy into the possession of the German emperor in 1032, and remained united with Germany till the 14th century. See DAUPHIN. There is a history by Chorier (2 vols. 1883). Auvergne (q.v.) was also a Dauphiné.

**Daurat**, or DORAT, JEAN, a French scholar, who played an important part in determining the course which his country's literature took at the time of the Renaissance. He was born about 1510, and became president of the Collège Coqueret, where he superintended the studies of Ronsard, Du Bellay, Baif, and Belleau. These poets, with whom he was united in the famous coterie of the Pléiade (see PLEIADES), he carefully trained for the task of reforming the vernacular, and ennobling French literature by the imitation of Greek and Latin models. He wrote nothing of importance in French, but devoted himself to guiding and stimulating the other members of the Pléiade, in whose works his learning and enthusiasm bore rich and enduring fruit. He died in 1588.

**Dauria**, a mountainous region of south-eastern Siberia, between Lake Baikal and the river Argun, on the Chinese frontier.

**Dauthendey**, MAX, German symbolist poet, was born at Würzburg, 25th July 1867, and died in Java in 1917. He also wrote plays and novels.

**Dauw**. See HORSE, QUAGGA, ZEBRA.

**D'Avenant**, SIR WILLIAM, English poet and playwright, was born in 1606 at Oxford, where his father kept the Crown Tavern, a house at which Shakespeare was in the habit of stopping when on his journeys between London and Stratford. A story arose later that D'Avenant's birth was due to an intrigue between his mother and the great dramatist, but for this there seems to be no foundation, though apparently D'Avenant himself was willing enough to barter his mother's reputation for the credit of such a parentage. Aubrey tells us that D'Avenant would often say, when pleasant over a cup of wine, that it seemed to him that he wrote with the very spirit that Shakespeare did, and 'seemed contented enough to be thought his son.' In his twelfth year the precocious boy penned an *Ode in Remembrance of Master Shakespeare*, not printed, however, until 1638. After a short period of study at Lincoln College, he became page to Frances, Duchess of Richmond; next passed into the household of the aged poet, Fulke Greville, Lord Brooke, and in 1628 took to writing for the stage. During the next ten years he produced many plays, the least poor of which were *The Cruel Brother* (1630) and *The Wits* (1636). In 1638, at the request of the queen, he was appointed poet-laureate in succession to Ben Jonson. About the same time he lost his nose through an illness—a calamity which laid him open to the merriment of such wits as Suckling, Denham, and Sir John Mennis. He afterwards

became manager of Drury Lane Theatre, but became embroiled in the intrigues of the Civil War, and was apprehended and hung into the Tower. He soon escaped to France, and returning, distinguished himself so much in the royalist cause, that he was knighted by Charles at the siege of Gloucester (September 1643). D'Avenant again got into difficulties, and was confined in the Tower for two years, when he was released, it is said, on the intercession of Milton. Once more he set about establishing theatrical representations, and in 1658 succeeded in opening a theatre. Two years earlier he had given what was practically the first opera in England, with Mrs Coleman as the first actress that ever appeared on an English stage. After the Restoration, D'Avenant was favoured by royal patronage, and continued to write and superintend the performance of plays until his death, April 7, 1668. His epic, entitled *Gondibert*, a feeble reaction from the romanticism of the Elizabethan poets, consists of fifteen hundred four-line heroic stanzas with alternate rhymes—a metre which the genius of Gray's *Elegy* can scarce save from the damning sin of monotony; much bepraised by its contemporaries, it now sleeps securely in the same oblivion with the author's *Madagascar*, and his great opera *The Siege of Rhodes*. A collected edition of his plays, with memoir, was edited by Logan and Maidment (Edin. 5 vols. 1872-74).—CHARLES D'AVENANT, his eldest son, was born in London in 1656, was educated at Balliol College, sat in parliament under James II. and William III., was commissioner of excise and joint-licenser of plays, under Anne secretary to the Commissioners for Union with Scotland, next inspector-general of imports and exports. He died 6th November 1714. Among his writings are *Discourses on the Publick Revenues* and *The Trade of England* (1698), and *A Discourse upon Grants* (1700).

**Davenport**, capital of Scott county, Iowa, on the Mississippi, opposite Rock Island (q.v.), 183 miles W. by S. of Chicago by rail. It is the seat of several Catholic institutions, has extensive manufactures of flour, wooden and iron wares, and woollen goods, and is the shipping depot of a large grain trade. Pop. (1880) 21,831; (1900) 35,254; (1920) 56,727.

**Daventry** (pronounced *Daintry*), an ancient municipal borough of Northamptonshire, at the sources of the Avon and Nene, 12 miles W. of Northampton, and 4 NW. of Weedon by a branch line opened in 1888. It is well built on an eminence, and has two principal streets. Charles I. spent six days here in 1645 before the battle of Naseby. Pop. 3500. A mile to the east is Danes or Bolough Hill, one of the largest Roman camps in the kingdom.

**David**, capital of Chiriquí (q.v.) in Panamá, lies in a fertile plain on the Rio David, which enters the Pacific 8 miles to the south. Stock-raising and the cultivation of tobacco are extensively engaged in, and there is a considerable trade. Pop. 15,000.

**David** (Heb., 'beloved'), the second king over Israel. He sprang from a family of Judah, and was the youngest son of Jesse, a man of some substance at Bethlehem. He is described as a handsome youth, 'red-haired, with beautiful eyes, and fair of face,' when he first distinguished himself in Israel by slaying the Philistine giant Goliath. After this heroic deed, Saul took him to his court, and appointed him to a military command. According to another account (1 Sam. xvi. 14-23) it was his skill in playing the harp, and his being sent for to banish the melancholy of Saul by that means, that first led to his coming into contact with the moody king. He had soon to flee from Saul's court,

as the king's jealousy of his supposed rival led him to seek David's life; but, by the craft of his wife Michal, Saul's daughter, and the friendship of Jonathan, Saul's son, he escaped, and fled to the country of the Philistines, where, however, he found refuge only for a short time. In the cave (or hill-fort) of Adullam, near Gath, he gathered a troop of 400 freebooters, which afterwards increased to 600, and with which he ranged through the country between Philistia and the Dead Sea, never attacking his king or countrymen, but always their enemies on the west and south, and levying contributions from the people of Judah for his protection of their flocks. The expeditions which Saul led against him frequently put him to great straits, and the difficulty of controlling his irregular force without assuming the offensive against 'the Lord's anointed' becoming ever greater, David left Judah, and became a vassal of the Philistine king of Gath, occupying for a year and four months the town of Ziklag in the desert to the south. After the death of Saul and Jonathan at Gilboa, he reigned seven and a half years in Hebron over the tribe of Judah, while Ishbosheth, Saul's son, ruled the rest of Israel with the help of Abner—probably as a vassal of the Philistines. On the death of Ishbosheth, all Israel chose David as king. He conquered the independent city of Jebus (Jerusalem), the strongest natural fortress in the country, and made it the political and religious centre of his kingdom, building, with the help of Tyrian artificers, a palace for himself on its highest hill Zion (the 'city of David'), and placing the Ark of the Covenant (q.v.) there under a tent—to be replaced under his successor by a temple, for which large collections of materials were made in David's reign. The nucleus of his army consisted of his old bodyguard of 600 *gibbōrim* (or 'heroes'), from which the officers of the general levy were drawn. A plan is described in Chronicles by which 24,000 were put under arms each month out of the 288,000 able-bodied men who were the fighting strength of the country. There was an additional regiment of life-guards, mostly foreigners ('*Crēthi* and '*Plēthi*'). In the course of a few years the conquest of the Philistines, Moabites, Arameans, Edonites, and Ammonites reduced the whole territory from Egypt to the Euphrates. During the siege of Rabbah, the Ammonite capital, David committed the greatest sin of his life, his adultery with Bathsheba and indirect murder of her husband. Henceforward 'the sword never departed from his house.' The last years of his long reign of thirty-two years in Jerusalem were troubled by popular disaffection, of which his favourite son Absalom availed himself to attempt a revolution, which nearly succeeded in placing him on the throne, but cost him his life, to David's excessive grief; and shortly before David's death—which was at earliest 1018, at latest 970 B.C.—another such unsuccessful attempt was made by another son, Adonijah, who was aggrieved at the choice of Solomon as his father's successor.

David is by far the greatest of the kings of Israel. The spirit of his rule is beautifully expressed in his 'last (poetic) words,' in 2 Sam. xxiii. 1-7. His personal courage, his skill and unvarying success in war, his foresight and circumspection in government, and his readiness to sacrifice merely personal ends to the welfare of his whole people are especially conspicuous. He 'executed judgment and justice unto all his people.' The foundation of his rich and complex character was his strong faith in Jehovah his God. It was this that distinguished him from Saul as 'the man after God's own heart.' He was no saint in the Christian sense, and in his lapses from veracity, his polygamy, and his cruel treatment of conquered enemies, he followed the customs

of his time. But the same unvarnished history which is the sole authority for the dark sides of his character is equally to be believed in its presentation of the brighter sides, and does not support the unfavourable judgment of David expressed by Bayle, Voltaire, Renan, and others, who would make him out either a licentious, cruel, and hypocritical despot, or simply a child of nature gifted with an equal share of great virtues and great vices.

There can be little doubt that the tradition which describes David as a musician and poet is true to fact—but whether any of his poems have been preserved is a much more debatable point. In the Psalter no less than seventy-eight psalms are ascribed to him, but most scholars are now agreed that they cannot all be his work. Ewald acknowledges only eleven psalms as Davidic, Hitzig fourteen, Delitzsch forty-four; Cheyne denies that any of the psalms are David's, but Driver is ready to admit the possibility. 'It is possible,' he says, 'that Ewald's list may be too large, but it is not clear that none of the psalms contained in it are of David's composition.' The psalms for which the best claims of a Davidic authorship can be made out are iii., iv., vii., viii., xv., xviii., xxiii., xxiv., xxxii.

The reign of David not only determined the political life of Israel, but also its conception of ideal glory. As the succeeding ages grew darker and more troubled, believing hearts in Israel turned back to those days of the kingdom's glory; men felt that only a king like David could restore the theocracy ordained of Jehovah; he formed the prototype for the Messianic hope that Jehovah would send a son of David, who should redeem Israel.

**David**, or DEWI, ST, the patron saint of Wales, first mentioned in the *Annales Cambriae* (10th century) as having died in 601, Bishop of Moni Judeonun, or Menevia, afterwards St Davids. He presided over two Welsh synods, at Brei and at 'Lucus Victoria.' A rich legendary history supplements these meagre but authentic details. Rhgyfarch tells that he was son of the king of Ceredigion, and a pupil of Paulinus, that he journeyed through Wales preaching and working miracles, visited Jerusalem, and denounced Pelagianism at Brei with such triumphant loudness that he was made by acclamation metropolitan Archbishop of Wales. Giraldus follows Rhgyfarch in his life; Geoffrey of Monmouth makes David the uncle of King Arthur, and says he, as archbishop, transferred the metropolitan see to Menevia—pure fables. See J. E. Lloyd's *History of Wales*, vol. i. (1911).

**David I.** (often called ST DAVID), king of Scotland, was the youngest of the six sons of Malcolm Ceanmhor and St Margaret (q.v.). Born about 1080, he was sent in 1093 to England along with his sister Matilda (who in 1100 married Henry I. of England), and remained for several years at the English court—a residence that powerfully affected his after career. There, as his contemporary William of Malmesbury puts it, he was 'polished from a boy' until he 'had rubbed off all the rust of Scottish barbarity.'

In 1107, when his elder brother Alexander succeeded to the throne, David, by express bequest of Eadgar, became Prince of Cumbria, with a territory which, besides part of the modern shire of Cumberland, included the whole district between the Tweed and Solway and the Firths of Forth and Clyde, except the shires of Haddington, Edinburgh, and Linlithgow. Over the greater part of this domain he appears to have held absolute sway. Alexander seems at first to have been inclined to

dispute David's right to the district, but the success of his claim was secured without contest by the influence of the great Norman barons who had by this time acquired extensive possessions in the south of Scotland, and to whom David's English training rendered him peculiarly acceptable. By David's marriage in 1110 to Matilda, widow of Simon de St Liz, and heiress of Waltheof, Earl of Northumberland, he still further increased his power, becoming Earl of Huntingdon and Earl of Northampton.

In 1124 he succeeded his brother on the Scottish throne, but had in 1130, and again in 1137, to fight for his crown against the heus of the old Celtic dynasties supported by the wild tribes of the north and west. On both occasions the Anglo-Norman chivalry which David had gathered around him gave him decisive victories. Having sworn, along with the other great barons of England, to maintain the right of his niece, Matilda, to the English crown, David took up arms on her behalf in 1155 when Stephen mounted the English throne, and penetrated into England as far as Durham, where at a meeting between him and Stephen peace was restored by the grant of the earldom of Huntingdon, and the promise of the earldom of Northumberland, to David's son Henry. In 1138 the war was, however, renewed, and the king of Scots, deserted by Bruce and others of his Anglo-Norman vassals who owned large estates in England as well as in Scotland, was signally defeated at the 'Battle of the Standard,' near Northallerton. The next year, a second peace was concluded, when the promised earldom of Northumberland was bestowed on Prince Henry.

The rest of David's reign—which marks the end of Celtic and the beginning of Feudal Scotland—was devoted to the accomplishment of the great designs begun by his father and mother, and continued by his two predecessors—the union of the different races of Scotland into one nation, and the civilisation of the people. How well he succeeded may be traced in the two centuries of prosperity that followed his reign. By the introduction of the feudal system, and the promulgation and vigorous personal superintendence of the working of wise laws, he endeavoured to secure the peace and safety of the country; and he looked for aid in this work to the Anglo-Normans whom he had brought from the south. By the erection of burghs he promoted the trade, manufactures, and commerce of the nation, and laid the foundations of its freedom. In his civilising efforts he depended also largely on the church, the extension and influence of which he greatly fostered and encouraged. Immediately after he became Prince of Cumbria he restored the fallen bishopric of Glasgow, and after his accession he founded and endowed the bishoprics of Ross, Aberdeen, Caithness, Brechin, and Dunblane; besides enriching the previously established sees of St Andrews, Moray, and Dunkeld, and reviving the old see of Galloway (Whithorn). He also founded or restored the abbeys of Kelso, Jedburgh, Melrose, Newbattle, Holyrood, Cambuskenneth, and Kinloss, as well as a number of minor religious establishments. So far indeed did this process of endowment go, that according to Bellenden, 'the crown was left indigent throw ampliation of gret rentis to the kirk,' a state of matters that led James I. (of Scotland) to remark, while standing by David's tomb at Dunfermline, that 'he was ane soir sanct for the crown.' On the other hand one who was a hard judge of monarchs—George Buchanan—said with much more truth, that 'if men were to set themselves to draw the image of a good king, they would fall short of what David showed himself throughout the whole course of his life.' Though King David

is often called St David, he was never formally canonised; but his name was inserted in the calendar prefixed to Laud's Prayer-book for Scotland, printed at Edinburgh in 1637.

King David died at Carlisle, 24th May 1153. His son Henry had died in the previous June, and he was succeeded by his grandson, Malcolm, then in his twelfth year.

The oldest Scottish painting now known to exist—an illuminated charter to the monks of Kelso, written in 1159—preserves rude miniatures of the young king Malcolm and his saintly grandfather. It is preserved at Floors Castle, and engraved in fac-simile in the *Liber S Marie de Calchou* (Bannatyne Club, 1846). See also Innes's *Scotland in the Middle Ages* (1860); Robertson's *Scotland under her early Kings* (1862); and Skene's *Celtic Scotland* (1876). The remains of David's legislation, including the interesting code of the *Leyes Burgorum*, have been carefully collected in the first volume of *The Acts of the Parliaments of Scotland* (1844).

**David II.**, only son of King Robert Bruce, was born at Dunfermline, 5th March 1324, and was married in 1328 to Edward II.'s daughter, Joanna. In June 1329 he succeeded his father, and in November 1331 was crowned, with his child-queen, at Scone. In 1334 the success of Edward Baliol (q.v.), and Edward III.'s victory at Halidon Hill (1333), forced David's guardians to send him and his consort to France, whence by the triumph of the national party he was permitted to return in 1341. Five years later, in fulfilment of his alliance with France, he invaded England, but at the battle of Neville's Cross, near Durham, was utterly routed by the Archbishop of York, 17th October 1346. For eleven years he remained a prisoner, in or near London, and at Odiham, in Hampshire; at length, in 1357, he was released on promise of a heavy ransom (100,000 merks), whose non-payment involved him in shameful dependence on England. In 1363 he actually proposed to his parliament that Edward III.'s second son should succeed him on the Scottish throne; and though the proposal was curtly rejected, the intrigue between the two kings was ended only by David's death at Edinburgh Castle, 22d February 1371. He was not forty-seven years old, yet his reign had lasted more than forty-one years—a reign as inglorious as it was long, but still of great moment to Scotland, since, 'from a war of conquest and patriotic resistance, the struggle had died into a petty strife between two angry nations, a mere episode in the larger contest which it had stirred between England and France.' Queen Joanna dying in 1362, David next year had married Margaret Logie, a comely widow, whom he divorced in 1369. By neither marriage had he any issue, so was succeeded by his sister's son, Robert II.

**David, FÉLICIEN**, a French composer, was born 8th March 1810, at Cadenet, in the department of Vaucluse. He was first a chorister in the cathedral of Aix, then at the age of twenty entered the Paris Conservatoire. He threw himself earnestly into the social speculations of his day; became an ardent disciple of St Simon, and afterwards of *Enfantin*; and finally, on the break-up of the brotherhood in 1833, he betook himself, along with several of his fellow-dreamers, to the East. The little knot of enthusiasts reached Constantinople, whence they made their way to Smyrna and Cairo. As they had no means, they suffered greatly from want, sickness, and ill-usage. In 1835 he returned to Paris, and published his *Mélodies Orientales* for the pianoforte. They were unsuccessful; and David remained in obscurity till 1844, when he brought out at the Conservatoire his *Désert*, a grand *Ode-symphonie*, as he called it, the words of which were furnished by his friend and fellow-wanderer, Auguste Colin. Its success was sudden

and complete. David was declared a master at once, and his *Désert* was performed in all the theatres. Subsequently, he travelled through Belgium and Germany, and was everywhere greeted with applause. Less successful works were—*Mose au Sinai* (1846), *Christophe Colomb* and *Le Paradis* (1847), *La Perle du Brésil* (1851), *Herculeum* (1859), and *Lalla Rookh* (1862). He composed also a quartette for strings, a nonette, a symphony, and songs. Appointed an officer of the Legion of Honour in 1862, and in 1869 librarian to the Paris Conservatoire de Musique, David died 29th August 1876.

**David, FERDINAND**, a distinguished violin virtuoso, born 19th June 1810, at Hamburg, was from thirteen a pupil of Spohr at Cassel, and became in 1836 concertmeister at Leipzig, which place he kept till his death at Klostern in the Grisons, 19th July 1873. His remarkable talent for teaching his instrument he showed after the establishment of the Leipzig Conservatorium, and many of the best violinists of his time were his pupils. His compositions were equally esteemed.

**David, GERHARD**, painter, born about 1450, at Oudewater in Holland, in 1484 entered the Painters' Guild of Bruges, of which he became dean in 1501. He died in Bruges in 1523. The National Gallery, London, contains an admirable example of his work in 'A Canon and his Patron Saints,' a wing from an altarpiece; and among his other pictures are a Madonna, in the museum at Rome; a Crucifixion, in Berlin; and a Baptism of Christ and a Descent from the Cross, both at Bruges.

**David, JACQUES LOUIS**, historical painter, was born at Paris, 31st August 1748. He received his first instruction from Boucher, his uncle, and at the age of twenty-one became a pupil of Vien. After several unsuccessful attempts he gained the 'prix de Rome' in 1774, and in the following year he settled in Rome, where Vien had been appointed director of the French Academy. Here he produced little in colour, but devoted himself to making accurate drawings from the antique. Six years later he returned to France, and his 'Belisarius' (1780) procured his admission to the Academy. Soon afterwards he married, and again visited Italy and also Flanders. It is in the works executed during this period, such as the celebrated 'Oath of the Horatii' (1784), 'The Death of Socrates' (1788), 'The Loves of Paris and Helen' (1788), and 'Brutus condemning his Son' (1789), that the classical feeling—founded upon sculpture and possessing much of its hardness as well as its clear-cut accuracy of form which was the painter's chief characteristic—is first clearly visible. During the Revolution David entered with enthusiasm into the political conflicts of the period. In 1792 he became a representative for Paris in the Convention. He voted for the death of Louis XVI., and was a member of the Committee of Public Safety; and he was the artistic director of the great national fêtes of the republic, which were founded on classical customs. After the death of Robespierre he was twice imprisoned, and narrowly escaped with his life. On his release in 1795 he devoted himself to his art, producing 'The Rape of the Sabines' (1799), which is usually ranked as his masterpiece. He was an original member of the Institute, and in 1804 was appointed court painter by Napoleon. After the restoration of the Bourbons, he was banished in 1816 as a regicide, and retired to Brussels, where, having declined an invitation to undertake the directorship of Fine Arts at Berlin, he died, 29th December 1825.

David's productions are distinguished by a certain austere dignity of conception and by elaborate

accuracy of form. On the other hand they are often cold and unreal in sentiment, unpleasantly monotonous in colouring, and defective in their arrangements of light and shade. His art and example exercised the most powerful effect upon the French school of painting; among his pupils were Girodet, Gros, Léopold Robert, Ingres, and Gérard; and the classicism which he introduced reigned supreme until the rise of the Romantic school headed by Géricault and Delacroix. The influence which in his later days he exercised upon the school of Belgium was hardly less marked and powerful. Fourteen of his works are in the Louvre, and five—including 'Bonaparte crossing the Alps' (1805)—are at Versailles. See *Le Peintre David*, by his grandson, J. L. Jules David (1880).

**David, PIERRE JEAN**, a French sculptor, known as David d'Angers, was born at Angers, 12th March 1789. In spite of the opposition of his father, a talented wood-carver, he resolved to become an artist; and after studying in the art schools of his native town, he made his way on foot to Paris in 1808, and placed himself under Jacques Louis David, the painter. In 1811 his 'Death of Epaminondas' gained the 'grand prix,' and David proceeded to Rome, where, though he became intimate with Canova, he preserved his own individuality, and produced works modern in feeling and full of strongly marked character. In 1816 he returned to France. A statue of the Great Condé, which he executed about this time, established his reputation. In 1826 he became a member of the Institute, and a professor in the School of Fine Arts; in 1828, and again in 1834, he visited Germany. During the July revolution he fought in the ranks of the people. For the new government he executed the pediment of the Panthéon (1835-37), by many thought his *chef d'œuvre*. In 1848 his well-known republicanism procured him a seat in the Constituent Assembly. After the *coup d'état* he was sent into exile, and went to Greece, but soon after returned. He died 5th January 1856. In the Museum of Angers about two hundred of David's works in relief and the round are preserved, as well as some four hundred of his medallions and many of his drawings.

**David ap Gwilym.** See GWILYM.

**Davidson, ANDREW BRUCE** (1831-1902), born in Aberdeenshire, was educated at Marischal College, Aberdeen, and at the Free Church College, Edinburgh, where in 1863 he was appointed to the chair of Hebrew and Old Testament exegesis. In this capacity he exercised a quite unusual personal influence upon his students, and through them did much to leaven the Free Church with a critical spirit fearless in method, but in the best sense conservative of the real essentials of faith. Beyond an occasional sermon or article in the *Expositor*, Dr Davidson seldom spoke outside his lecture-room, and published little, and that rather suggestive than demonstrative of his power as an exegete. A member of the Old Testament Revision Committee, he contributed to *Chambers's Encyclopædia*; among his books are a short treatise on Hebrew accentuation (1861), an unfinished commentary on Job (1862), an *Introductory Hebrew Grammar* (1874), admirable short Commentaries on Job, Hebrews, and Ezekiel; and a posthumous volume of sermons, with a prefatory memoir by Taylor Innes. See *Life* by J. Strahan (1917).

**Davidson, JOHN**, born at Barrhead in 1857, went to London in 1890, established his reputation with *Fleet Street Eclogues* (1893), and continued to publish ballads, plays, romances, &c. till his suicide (due to difficulty in making a living) in 1909.

**Davidson, SAMUEL** (1807-98), one of the ablest of English exegetes, born near Ballymena

in Ireland, educated at the Royal College of Belfast, entered the Presbyterian ministry, and was called in 1835 to the chair of Biblical Criticism in his own college. Becoming a Congregationalist, he was called in 1842 to the chair of Biblical Literature and Oriental Languages in the Congregationalist College at Manchester, but, regarded as too 'advanced,' resigned in 1857. He was a member of the Old Testament Revision Committee. See his *Autobiography* (1899).

**Davies, Sir Henry Walford**, born at Oswestry in 1869, studied and taught at the Royal College of Music, was an organist, conducted the Bach Choir, and became professor at Aberystwyth and Director of Music for the University of Wales. He composed many cantatas, song-cycles, &c.

**Davies, Hubert Henry**, playwright, born at Woodley, Cheshire, was a journalist in San Francisco, returned to England in 1901, lost his health by war-work, and disappeared in 1917. His plays—*The Mollusc*, *A Single Man*, *Doormats*, *Outcast*, &c.—show a touch that has been compared with Jane Austen's. They have been collected, with a memoir by Hugh Walpole (1921).

**Davies, Sir John**, poet and statesman, was born of a good family at Tisbury, Wiltshire, in 1569. At sixteen he entered Queen's College, Oxford, whence he passed to the Middle Temple. He was called to the bar in 1595, but was disbarred three years later for breaking a stick in the dining-hall over the head of a wit whose raillery had provoked him. He returned to Oxford, and there wrote his long didactic poem on the immortality of the soul, *Nosce Teipsum*, in 1599. Spite of the difficulties of a formal poem upon such a theme, it is a fairly successful performance, clear, vigorous, and sincere, though quite devoid of passion or imagination. The verse is that of the *Annus Mirabilis* and Gray's *Elegy*. Davies had already published in 1595 his *Orchestra*, or a *Poeme of Dancing*, 'a sudden rash half-capreol of my wit.' It is written in seven-line stanzas in imitation of Spenser, and is a graceful and harmonious poem on the conceit that all natural phenomena are subject to a regulated motion here called dancing. In 1599 Davies published also his *Hymns to Astraea*, a collection of clever acrostics each making the name Elizabeth Regina. He contributed also to *England's Helicon* and to Francis Davison's *Poetical Rhapsody*. In 1601, after ample apologies, Davies was readmitted to the society of the Middle Temple, and was returned to parliament for Corfe Castle. On the death of Elizabeth he accompanied commissioners in their journey to the Scottish court, and quickly came into favour with James I., who sent him in 1603 as solicitor-general to Ireland. Three years later he became Irish attorney-general, serjeant-at-law, and a knight. He sent many statesman-like letters and reports to Cecil, supported severe anti-Catholic and repressive measures, and took an important part in the plantation of Ulster. He sat in the Irish parliament for Fermanagh, and was for some time its speaker; but was returned to the English parliament in 1614 for Newcastle-under-Lyme, and resigned his office at Dublin in 1619, continuing to practise as king's serjeant in England. He was nominated chief-justice in November 1626, but died suddenly of a fit of apoplexy about a month after. He collected his three chief poems into one volume in 1622. His complete works were collected by Dr Grosart in 1869-76.—His widow, Eleanor Touchet, daughter of Baron Audley, whom he had married in 1609, married again, and survived till 1652. She was crazy enough to imagine herself a prophetess; but her exertations brought her nothing save fine, imprisonment, and ridicule (see ANAGRAM).

**Davies, John** (1565-1618), 'of Hereford,' not to be confounded with Sir John Davies (q.v.), was a writing-master, whose poetry is not without merit, although prolix and tedious. His chief long poems are *Murum in Modum*, *Microcosmus*, and *Summa Totalis*. In his collection of three hundred poor epigrams (about 1611) is one addressed 'To our English Terence, Mr Will. Shake-speare.' His works were collected by Dr Grosart in 1873.

**Davies, William Henry**, born in 1870 at Newport, Monmouth, was a tramp in America for six years, sometimes crossing the Atlantic with cattle, then a pedlar and street-singer in England for eight years. Afterwards he wrote, besides *The Autobiography of a Super-tramp* (1908) and other prose books, many volumes of verse which gained him a foremost place among the lyrical poets of his time, especially as a poet of nature. Two series of *Collected Poems* appeared, 1919-23; *True Travelers: an Opera*, in 1923; and *Later Days* in 1925.

**Davila, Enrico Caterino**, a celebrated Italian historian, was born at Pieve di Sacco, in the vicinity of Padua, in 1576. When seven years old he was taken to France for his education, and at the age of eighteen he entered the service of Henry IV., which he afterwards exchanged for the military service of Venice. In 1631 he was assassinated while on his way to Crema. Davila has been rendered famous by his work, entitled *Storia delle Guerre civili di Francia* (1630; trans. Aylesbury and Cotterell, 1647). See also BALBOA, ÁVILA.

**Da Vinci.** See LEONARDO DA VINCI.

**Davis, Jefferson**, president of the Confederate States, was born in Christian county, Kentucky, June 3, 1808. He studied at Transylvania College, and at the United States military academy at West Point, where he graduated in 1828. Entering the army, he served in several frontier campaigns, but resigned his commission in 1835. He entered congress in 1845 as a representative from Mississippi, and served in the Mexican war (1846-47) as a colonel of volunteers, in which capacity his bravery won high commendation. He was appointed to the United States senate in 1847, and re-elected in 1848 and 1850; in 1851 he made an unsuccessful canvass for the governorship of Mississippi. From 1853 to 1857 he was Secretary of War under the presidency of Franklin Pierce. After this he returned to the senate, where he succeeded Calhoun as the leader of the extreme State Rights party. He was the author of the seven resolutions passed in May 1860 by the senate, in which it was virtually asserted that neither congress nor the legislature of any territory could prohibit slavery in such territory, but that both were bound to protect property in slaves; that the people of no territory could prohibit slavery until after the adoption of a state constitution; and that congress could neither prohibit nor permit the institution of slavery in any state applying for admission into the Union. The refusal of the lower house of congress to concur in these resolutions led to great popular agitation in the South. The failure of the Democratic National Convention at Charleston to adopt resolutions embodying substantially the same ideas had already (May 1, 1860) caused the disruption of that body and of the Democratic party; and the election of Lincoln, the Republican candidate, to the presidency was an immediate result of this division of the Democrats. In January 1861 the state of Mississippi seceded from the Union, and as a consequence Davis left the senate. A few weeks later he was chosen president of the Confederate States under their provisional form of government. In the November following he was without opposition elected president of the confederacy for a term of six years. The history of his presidency is that

of the war of 1861-65 (see UNITED STATES). In May 1865, after the collapse of his government, Davis was captured by a force of Union cavalry. After two years' imprisonment in Fortress Monroe he was released on bail, and though he had been indicted for treason, was never brought to trial, a *nolle prosequi* being entered in his case in 1868. After 1879 he resided on an estate bequeathed to him in Mississippi; and in that year he was specially excepted in a bill to pension veterans of the Mexican war. In 1881 he published *The Rise and Fall of the Confederate Government*; he dedicated a soldiers' monument at Montgomery; and he died 6th December 1889. See his *Life* by Alfriend (1868), Pollard (1869), and his widow (1891); also Craven, *The Prison-life of Jefferson Davis* (1866).

**Davis, JOHN**, an English navigator, was born at Sandridge, near Dartmouth, about 1550, and is principally distinguished for having undertaken in 1585 and the two following years three voyages to the Arctic Seas in search of a north-west passage. In the last voyage, he sailed with a bark of apparently not over twenty tons, as far north as the 73d degree of latitude, and discovered the strait which bears his name. He next made two ill-fated voyages towards the South Seas, and as pilot of a Dutch vessel bound to the East Indies. In his last voyage as pilot of an English ship of 240 tons he was killed in a brush with some Japanese pirates at Bintang, near Singapore, 30th December 1605. His writings, *The World's Hydrographical Description* (1595) and *The Seaman's Secrets* (1594), were edited for the Hakluyt Society in 1878 by Captain A. H. Markham, with a biographical introduction. Here it is pointed out that Davis is often confounded with John Davis of Limehouse, a navigator to the East Indies, who died at Batavia in 1622, and published in 1618 *A Ruter or Briefe Direction for Readie Sailings into the East India*, which will be found in Part I. of *Purchas his Pilgrimes*.

**Davis, THOMAS OSBORNE**, Irish poet and patriot, born at Mallow, 14th October 1814, son of an army surgeon. At Trinity College, Dublin, he read hard and graduated, and, after spending nearly three years in London and on the Continent, was called to the bar after his return to Dublin in 1838. Next year, though a Protestant, he joined the Repeal Association, and in 1841 became for a short time joint-editor with John Dillon of the *Dublin Morning Register*. In the July of 1842, with Dillon and Duffy, he founded the famous *Nation* newspaper, the chief aim of which was 'to direct the popular mind and the sympathies of educated men of all parties to the great end of nationality.' It was the first time that conspicuous literary ability had been devoted to the cause, and ere long its bright vigorous articles and stirring as well as pathetic songs, many of them from the pen of Davis himself, made the pages of the *Nation* dear to Irishmen all over the island. Davis started a projected series of Irish orators with the *Speeches of Curran* (1844), and wrote a good 'Essay on Irish Songs' for Barry's *Songs of Ireland* (1845). But his bright and promising career was soon closed by his premature death of fever, in Dublin, 16th September 1845. His *Poems* were published in 1846; his *Essays* in 1847; *Literary and Historical Essays* in 1915. See the *Memoir* by Sir C. G. Duffy (1890).

**Davis Strait** washes the western coast of Greenland, and connects Baffin Bay with the Atlantic Ocean. At its narrowest point, immediately north of the Arctic circle, it measures about 200 miles across. In 1888 the identity between Ginnunga Gap, referred to in the Sagas, and the present Davis Strait was demonstrated.

**Davits**, on shipboard, are upright columns of forged iron, curved at their upper ends, which pro-

ject, or may be made to project, over a vessel's side or stern, and are used as a kind of crane to hoist, suspend, or lower a boat. They are arranged in pairs, one for each end of the boat. See *BOAT*.

**Davitt, MICHAEL**, founder of the Irish Land League, the son of a Mayo peasant, was born near Straid, County Mayo, in 1846. Evicted from their small holding, the family emigrated to Hastingsden in Lancashire (1851); and here six years later the boy lost his right arm through a machinery accident in a cotton-factory. Having in 1866 joined the Fenian movement, he was sentenced in 1870 to fifteen years' penal servitude, but released in 1877, and began the anti-landlord crusade which culminated in the Irish Land League (1879). In 1881-82 he was imprisoned in Portland for breaking his ticket-of-leave; his *Leaves from a Prison Diary* were published in 1885. The socialistic views of the 'Father of the Land League,' especially on land nationalisation, did not harmonise with those of the other Home Rulers. In 1892 he was sent to parliament as anti-Parnellite, unseated on the ground of clerical and other intimidation, but immediately returned unopposed for NE. Cork. Having resigned in 1893 and been returned unopposed for S. Mayo, he withdrew finally in 1899. He travelled on the Continent, in America, Egypt, and South Africa during the war, and published a *Defence of the Land League* (1891), *Life and Progress in Australia* (1898), *The Boer Fight for Freedom* (1902), *Within the Pale* (1903), and *The Fall of Feudalism in Ireland* (1904). He died 30th May 1906. See *Life* by Sheehy-Skeffington (1908).

**Davos** (Romansch *Tavau*) is a small valley lying amongst the Alps of the Eastern Gisons, 10 miles SE. of Coire (40 by rail). The valley, enclosed by lofty hills, is famous as a holiday and health resort in winter, especially for such as suffer from chest disease. The air is still and dry, and throughout the winter there is a great deal of bright, warm sunshine. Once out-of-the-way hamlets, Davos-Platz (5100 feet above sea-level) and Davos-Dorfl have now numerous hotels, villas, and chalets, which accommodate tourists and invalids (over 20,000 and 10,000 respectively in some years). Davos is a favourite winter-sport centre (skiing, skating, bob-sleighbing, tobogganing, curling). The 11,200 inhabitants of the valley, which till 1848 was one of the 26 independent republics of the Grisons, are mostly German Protestants. See J. A. Symonds, *Our Life in the Swiss Highlands* (1892).

**Davout** (not DAVOUST), LOUIS NICOLAS, French marshal, was born 10th May 1770, at Annoux, in Burgundy; was educated along with Bonaparte at the military school of Brienne; and in 1788 became lieutenant in a cavalry regiment. During the revolutionary wars he rose to the rank of general. He accompanied Bonaparte to the East, where he mainly contributed to the victory at Aboukir, and otherwise distinguished himself both in Upper and Lower Egypt. On his return to France, he was named general of division in 1800, commander-in-chief of the consular grenadier guards in 1800, and marshal of the empire in 1804. He acted a brilliant part in the great victories obtained by the French at Austerlitz (1805) and Auerstadt, and was created by the emperor Duke of Auerstadt (July 2, 1808). On the renewal of the war with Austria in 1809, Davout rendered useful service at Eckmühl (22d April); and at Wagram, where he commanded the right wing, he succeeded in turning the enemy's left, and so first checked the Austrians' attack. In 1811 he was created Prince of Eckmühl. Appointed governor of Poland, he ruled that country in a spirit of the harshest despotism, and provoked the reproaches of the emperor, but,

nevertheless, did not forfeit his esteem. In the Russian campaign of 1812 he gathered fresh laurels on the fields of Mohilev and Vitebsk (27th July). After the retreat from Moscow, Davout became governor-general of the Hanse towns, and at Hamburg, though hated for his cruelty, resolutely maintained himself till the restoration of the Bourbons. On the return of Bonaparte from Elba, Davout was appointed war-minister, and as such showed a remarkable genius for the rapid organisation of troops and supplies. After the battle of Waterloo, he received the command of the remnant of the French army under the walls of Paris. He would have continued the contest had he not been ordered by the Provisional Government in the capital to conclude a military convention with the Allies. In 1819 he was made a peer of France. His death took place June 1, 1823. Firmness of character and dauntless courage were Davout's leading characteristics; but his military severities often went the length of harshness, and even cruelty, while his rapacity had in it something akin to barbarism. See his *Correspondance* (4 vols. 1885), and his *Life* by Chénier (1886), by his daughter, the Marquise Blocqueville (3 vols. 1879-80), and by Montégut (1882).

**Davy, SIR HUMPHRY**, one of the greatest chemists, was born 17th December 1778, at Penzance, Cornwall, where his father was a carver in wood. At the school at Penzance, and afterwards at Truro, he developed a taste for storytelling, poetry, and angling, and for experimental science, in which he was aided by Dunkin, a saddler. In 1793 he became apprentice to a surgeon and apothecary in Penzance, wrote verses, and indulged in chemical experiments. He at the same time entered upon a course of study all but universal. 'Speculations on religion and politics, on metaphysics and morals, are placed in his notebooks in juxtaposition with stanzas of poetry and fragments of romance.' The study of natural philosophy brought him near to that department which was to be his own; but it was not till he had reached his nineteenth year that he entered seriously upon the study of chemistry. He was then introduced to the notice of Dr Beddoes (q.v.), who in 1798 established a Pneumatic Institute at Clifton, and took him as his assistant. Here he made the acquaintance of the Earl of Durham, of Coleridge, and Southey, and carried on a course of experiments on the respiration of different gases, in which he had more than once nearly sacrificed his life. He thus discovered the singular exhilarating effect of nitrous oxide when breathed. The account which he published in his *Researches Chemical and Philosophical* (1799), although afterwards regretted, established his reputation, and led to his appointment, at the age of twenty-two, as lecturer to the Royal Institution of London. He delivered his first lecture in 1801; and his eloquence, and the novelty and variety of his experiments, soon attracted crowded and brilliant audiences. In 1803 he began researches connected with agriculture, on which he delivered a course of epoch-making lectures, which were published under the title of *Elements of Agricultural Chemistry* (1813). The discoveries, however, on which Davy's fame as a chemist chiefly rests, took their origin in the views which he developed in 1806, in his Bakerian lecture, *On Some Chemical Agencies of Electricity*. This essay was universally regarded as one of the most valuable contributions ever made to chemical science, and obtained the prize of the French Institute. Following out his principle, he was led to the grand discovery that the alkalis and earths are compound substances formed by oxygen united with metallic bases. It was potash that he first suc-

ceeded in decomposing, on the 19th October 1807. When he first saw the globules of the new metal, *potassium*, his delight is said to have been so ecstatic that it required some time for him to compose himself to continue the experiment. He next decomposed soda and the alkaline earths, baryta, strontia, lime, and magnesia; and discovered the new metals, *sodium*, *barium*, *strontium*, *calcium*, and *magnesium*. With regard to the earths proper, he succeeded in proving that they consist of metals united to oxygen. It was reserved for Wohler and others to exhibit the metals by themselves. He lectured in Dublin in 1808-9, and received the honorary degree of LL.D. from Trinity College.

On 8th April 1812 Davy was knighted; he married Mrs Apreece, a lady of considerable wealth, daughter and heiress of Charles Kerr of Kelso, and resigned the chemical chair of the Royal Institution, April 1813. In order to mark the high sense of his merits, he was elected honorary professor of Chemistry. He discovered the talents of Faraday (q.v.), for whom he secured the appointment as assistant in the laboratory of the Royal Institution. That he might investigate his new theory of volcanic action, he received permission from the French government—though the two countries were then at war—to visit the Continent, and was received with the greatest distinction by the scientific men of France. He was accompanied by Faraday. On returning to England in 1815, he entered on the investigation of the nature of fire-damp, which is the cause of explosions in coal-mines. This resulted in the invention of the Safety-lamp (q.v.). A public subscription of about £1500 was collected as a testimonial by those interested in 1817, and he was entertained to dinner, and presented with a service of plate. He was created a baronet, 20th October 1818. On the death of Sir Joseph Banks in 1820, Sir Humphry Davy was elected President of the Royal Society. In 1820-23 his researches on electromagnetism were communicated to the Society. He invented an ingenious plan for preventing the corrosion of the copper-sheathing of ships by altering the electric condition of the copper by means of bands of zinc; but the bottoms of the vessels became so foul from the adhesion of weeds and shells that the plan had to be abandoned.

Early in 1825 Sir Humphry Davy had begun to complain of the loss of strength, and in 1826 he had an apoplectic attack. He made two journeys to the Continent for the recovery of his health, and died at Geneva on the 29th May 1829, at the early age of fifty-one. The Genevan government evinced their respect by a public funeral. He was a member of almost all the scientific institutions in the world. Cuvier, in his *Eloge*, says: 'Davy, not yet fifty-two years of age, occupied, in the opinion of all that could judge of such labours, the first rank among the chemists of this or of any other age.' Another critic has said: 'He was not only one of the greatest, but one of the most benevolent and amiable of men.' His widow placed a tablet to his memory in Westminster Abbey, and a statue was erected to him in Penzance. Besides the works already mentioned, and a great number of contributions to the *Philosophical Transactions*, Sir Humphry Davy was author of *Elements of Chemical Philosophy* (1812); *On the Safety-lamp in Coal-mines* (1818); *Salmonia, or Days of Fly-fishing* (1828); and *Consolations in Travel* (1830)—all included in his *Collected Works* (9 vols. 1839-40).

See *Memoirs of the Life of Sir Humphry Davy*, by his brother, John Davy (1836); his *Fragmentary Remains* (1858); the *Life* by Dr Paris (1831); and that by Dr T. E. Thorpe (1896).

**Davy, JOHN**, musician, was born near Exeter in 1763, and died in London in 1824. Many of his songs were great favourites, and though most are

forgotten, 'The Bay of Biscay' has never lost popular favour.

**Davy Jones**, a sailor's familiar name for a malignant sea-spirit or the devil generally. The common phrase 'Davy Jones's locker' is applied to the ocean as the grave of men drowned at sea. A dubious explanation of the name makes it compounded from *Duffy*, a West Indian negro spirit name, and the scriptural prophet Jonah, in jocular allusion to his somewhat unusual adventures.

**Davy Lamp.** See SAFETY-LAMP.

**Dawalla** (*Hypophthalmus dawalla*), a fish of the family Siluridae, found in the rivers of Guiana, and highly esteemed for the delicacy of its flesh. It is sometimes 2½ feet long, and is brightly coloured. The eye is situated below the angle of the mouth.

**Dawes**, RICHARD (1708-66), Hellenist, born near Market Bosworth, was a fellow of Emmanuel, Cambridge, and schoolmaster in Newcastle (1738-49), and retired to Heworth, in Durham, where he solaced himself with rowing and campanology.

**Dawkins**, SIR WILLIAM BOYD, was born at Buttington vicarage, near Welshpool, Montgomeryshire, 26th December 1838, and educated at Rossall School and Jesus College, Oxford. In 1861 he joined the Geological Survey, became curator of Manchester Museum in 1870, and professor of Geology in Owens College (afterwards Manchester University) in 1872. In 1882 he presided over the anthropological section of the British Association at Southampton, and was elected honorary fellow of his old college. The Channel Tunnel Committee employed him in 1882 to make a special survey of both coasts; and next year he laid down the line for a tunnel under the Humber. Sir W. Boyd Dawkins has contributed numerous papers to learned societies relating especially to fossil mammalia. His books are *Cave-hunting: Researches on the Evidences of Caves respecting the Early Inhabitants of Europe* (1874), and *Early Man in Britain, and his place in the Tertiary Period* (1880), the latter a work of great interest.

**Dawlish**, a pleasant watering-place, on the S.E. coast of Devonshire, backed by the Great Haldon (818 feet), 12 miles S. by E. of Exeter; pop. 4700.

**Dawn.** See TWILIGHT.

**Dawson**, GEORGE, a busy and popular preacher and lecturer, was born in London, 24th February 1821, taught for a time in his father's academy, and studied at Aberdeen and Glasgow. He became pastor of Rickmansworth Baptist Chapel in 1843; of Mount Zion, Birmingham, in 1844, where his eloquence, breadth of view, and entire freedom from conventionality drew crowds to his services. Dawson's doctrinal position, which did not allow of his being fettered by theological forms of belief, led to his resignation; the 'Church of the Saviour' was built for him (1847), which borrowed its ritual from many sources. He took a lively interest in politics; was extremely popular as a lecturer for thirty years; popularised the views of Carlyle and Emerson, with both of whom he was personally acquainted; taught English literature classes at the Midland Institute for six years; advocated free libraries, and was one of the founders of the Shakespeare Memorial Library, Birmingham. Since his sudden death at King's Norton, near Birmingham, 30th November 1876, various works have been published: *Sermons* (4 vols. 1878-82), *Prayers* (2 vols. 1878-83), *Biographical Lectures* (2 vols. 1886-87), and *Every Day Counsels* (1888). See the Memoir by Crosskey (1876).

**Dawson**, SIR JOHN WILLIAM, geologist and naturalist, was born at Pictou, Nova Scotia, October 1820. He studied at Edinburgh, and afterwards devoted himself to researches in the

natural history and geology of Nova Scotia and New Brunswick, aiding Sir Charles Lyell in his investigations in Nova Scotia in 1842 and again in 1852. He was appointed superintendent of education in Nova Scotia in 1850; principal of McGill University, Montreal (1855), and afterwards vice-chancellor. In 1884 he was knighted; and he was an LL.D. of Edinburgh, &c. His *Devonian and Carboniferous Flora of Eastern North America* records the discovery of what he believed to be the lowest known form of animal life, the Eozoon Canadense of the Laurentian limestone (see EOOZON). An anti-Darwinian, he published *Archaia* (1858), *Story of the Earth and Man* (1872), *Dawn of Life* (1875), *Origin of the World* (1877), *Fossil Men* (1878), *Change of Life in Geological Time* (1880), *Egypt and Syria* (1885), *Geology and History* (1894), and *Relics of Primeval Life* (1897). He died 19th November 1899.

**Dawson**, capital of the Yukon territory of Canada, is situated amidst impressive scenery at the junction of the Klondike and Yukon Rivers, and was founded in 1896 on the discovery of gold in the district. Although partly destroyed by fire in 1899, it is a busy and well-equipped town, having good steamer connection with the upper and lower Yukon. It is 1500 miles from the mouth of the great river. Though in winter the temperature falls to -50° or lower, it may in summer be 90° in the shade; and good wheat, barley, and oats have been ripened here. Pop. 1000.

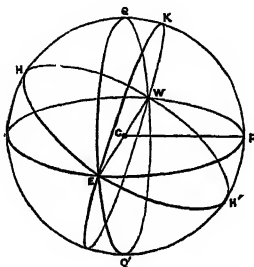

**Dax**, a town in the French department of Landes, on the Adour, 93 miles S. by W. of Bordeaux by rail. It has a 14th-century castle, remains of Roman walls, a cathedral, and is remarkable for its hot sulphur-springs (77°-144° F.), whose waters, known to the Romans as *Aque Tarbellæ*, are used in cases of rheumatism and nervous complaints. In the middle ages it was called Acqs. It has a trade in turpentine, resin, pitwood, horses, and hams. Pop. 11,000.

**Day** originally meant the space of time during which it is light, in opposition to the space of darkness or night; it now more usually denotes a complete alternation of light and darkness. It is the earth's rotation that causes the vicissitude of day and night. The earth being a globe, only one-half of it can be lighted up by the sun at once; to that half it is day, while to the other half, which is in shade, it is night. But by the earth's rotation, the several portions of the surface have each their turn of light and of darkness. This happens because the position of the earth is such that the equator is on the whole presented towards the sun; had either pole been towards the sun, that hemisphere would have revolved in continual light, the other in continual darkness.

One complete rotation of the earth does not make a day, in the usual sense. If the time is noted when a particular fixed star is exactly south or on the meridian, when the same star comes again to the meridian the next day, the earth has made exactly one rotation, and the time that has elapsed is called a *sidereal day*. This portion of time may be regarded as being always of the same length; for the motion of the earth on its axis differs extremely little from absolute uniformity. Hence sidereal or star-time is much used by astronomers. But the passage of a star across the meridian is not a conspicuous enough event for regulating the movements of men in general. It is not a complete rotation of the earth, but a complete alternation of light and darkness that constitutes their day. This, which is called the *civil* or the *solar day*, is measured between two meridian passages of the sun, and is about four minutes longer than the sidereal day. The cause of the greater length is

this : When the earth has made one complete turn, so as to bring the meridian of the place to the same position among the fixed stars as when it was noon the day before, the sun has in the meantime (apparently) moved eastward nearly one degree among the stars, and it takes the earth about four minutes more to move round so as to overtake him. If this eastward motion of the sun were uniform, the length of the solar day would be as simple and as easily determined as that of the sidereal. But the ecliptic or great circle in which the sun apparently moves crosses the equator, and therefore one portion of the sun's apparent path is more obliquely inclined to the equator than another; besides, as the earth moves in her orbit with varying speed, the rate of the sun's apparent motion in the ecliptic must also vary. The consequence is, that the length of the solar day is constantly fluctuating; and to get a fixed measure of solar time, astronomers have to imagine a sun moving uniformly in the celestial equator, and completing its circuit in the same time as the real sun. The time marked by this imaginary sun is called *mean solar time*; when the imaginary sun is on the meridian, it is *mean noon*; when the real sun is on the meridian, it is *apparent noon*. It is obvious that a sun-dial must show apparent time, while clocks and watches keep mean time. Only four times in the year do these two coincide. The difference is called the *equation of time*, because, when added to or subtracted from apparent time, according as the sun comes too soon or too late on the meridian, it makes it equal to mean time. The mean solar day is divided into twenty-four hours, the hours into minutes and seconds. A sidereal day, we have seen, is shorter; its exact length is 23 hours, 56 minutes, 4 seconds of mean solar or common time. Astronomers divide the sidereal day also into twenty-four hours, which are of course shorter than common hours. In the course of a civil year of 365 days, the earth turns on its axis 366 times, or there are 366 sidereal days. Astronomers reckon the day as beginning at noon, and count the hours from 1 to 24. The civil day begins at midnight, and the hours are counted in two divisions of twelve each. The ecclesiastical day was reckoned from sunset to sunset. The Greeks counted their day from sunset, as did also the Hebrews, the Romans from midnight, the Babylonians from sunrise, the Umbrians from mid-day.

The diagram will explain the variation in the relative duration of light and darkness at different times of the year and different parts of the earth's surface. C represents

zon. When the sun is on the equator it is obvious that the arcs EQW and EQ'W are equal—i.e. the sun is as long above the horizon as it is below it. But, if the sun be in the northern half of the ecliptic, its apparent path is a circle parallel to EQW passing through the sun's position; and more of this circle is above the horizon than below it. Similarly we can explain the appearances for other positions of the sun and of the observer.

Day, as opposed to night, varies with the latitude and the season of the year. As we go north from

the equator it *increases* in summer, and *decreases* in winter. At the equator, day is a little more, night a little less than twelve hours; at the poles, day is a little more, night a little less, than six months. For the time of day in different countries, see *TIME*.

A *day*, in Law, includes the whole twenty-four hours from midnight to midnight. In reckoning periods of time from a certain event, the day on which the event occurred is excluded. On the other hand, if it be required to prove survival for a certain number of days, it will suffice if the person be alive for any portion, however small, of the last day. While an obligation to pay on a certain day would therefore be theoretically discharged by payment before midnight, the law requires that reasonable hours be observed—e.g. if the payment (as a bill) is at a bank or place of business, it must be within business hours.

A *lawful day* is a day on which there is no legal impediment to the execution of a writ—i.e. all days except Sundays and fast-days appointed by government. Criminal warrants, and in Scotland warrants against debtors in *meditatione fugæ*, are an exception to this rule, and may be both granted and executed on Sundays and fast-days. By 29 Car. II. chap. 7, all contracts made by persons in their ordinary calling on a Sunday are void. The exceptions to this rule will be explained under *SABBATH*. In England, Christmas-day and Good-Friday generally stand on the same footing with Sundays and fast-days appointed by royal proclamation; but in Scotland there is no exception made in favour of any of the feast or fast days of the church.

*Days of Grace*.—The time at which a bill is actually *due* and payable, except in the case of bills payable on demand or at sight, is three days after the time expressed on the face of it, and these three additional days are called *days of grace*. If the third day of grace fall on a Sunday, Christmas-day, Good-Friday, or a national fast or thanksgiving day, the bill is payable the day before. If it fall on any of the other bank holidays, or if the last day of grace is a Sunday and the second a bank holiday, the bill is payable on the succeeding business day (see *BILL*). Days of grace have now been abolished in many countries, but there are still three allowed in the United States, and ten in Russia.

**Day, JOHN** (1522-84), a native of Dunwich, was an early London printer, his most celebrated production being Foxe's *Book of Martyrs*.

**Day, JOHN**, a dramatist, of whose life hardly anything is known. He is mentioned in Henslowe's *Diary* in 1598 as an active playwright. But few of his earlier works have come down to us save *The Blind Beggar of Bednal Green*. Day collaborated freely with contemporary writers, as Chettle and Dekker. Ben Jonson in his conversations with Drummond of Hawthornden grouped him with some other admirable gentlemen and authors as a rogue and a base fellow. His best works that have reached us are a graceful comedy, *Humour out of Breath*, and *The Parliament of Bees*, a kind of allegorical masque in which all the characters are bees. 'The very air,' says Charles Lamb, 'seems replete with humming and buzzing melodies. Surely bees were never so berhymed before.' An edition of Day's works was privately printed by A. H. Bullen in 1881.

**Day, THOMAS**, the author of *Sandford and Merton*, was born in London, 22d June 1748, and thirteen months later, by his father's death, became heir to £900 a year. From the Charterhouse he passed to Corpus Christi College, Oxford, where he formed a close friendship with Richard Lovell

Edgeworth (q.v.). In 1765 he entered the Middle Temple, in 1775 was called to the bar, but he never practised. A good, clever eccentric, a disciple of Rousseau, he brought up two children, an orphan blonde and a foundling brunette, one of whom should presently become his wife. That scheme miscarried; and, admitted to the Lichfield coterie, he proposed first to Honora Sneyd, next to her younger sister Elizabeth. She sent him to France to acquire the French graces; as acquired by him, they but moved her to laughter. Finally in 1778 he married an appreciative heiress, Esther Milnes, and spent with her eleven happy years, farming on philanthropic and costly principles in Essex and Surrey, till on 28th September 1789 he was killed by a fall from a colt he was breaking in. His wife died broken-hearted two years afterwards. Two only of Day's eleven works call for mention—*The Dying Negro* (1773), and the *History of Sandford and Merton* (3 vols. 1783–89). The poem struck the keynote of the anti-slavery movement; the child's book, like its author, is sometimes ridiculous, but always excellent. See *Lives of Day* by Keir (1791), and Blackman (1862).

**Dayaks.** See DYAKS.

**Dayanand Saraswati.** See ARYA SAMAJ, BRAHMA SAMAJ.

**Day-fly.** See EPHEMERA.

**Day-lily** (*Hemerocallis*), a perennial herbaceous genus of Liliaceæ, so named from the ephemeral flowers, which, however, succeed each other freely upon the peculiar inflorescence (a double bostyx). Several species are cultivated in gardens, especially

Yellow Day-lily (*Hemerocallis flava*).

the fragrant Yellow Day-lily (*H. flava*), a native of warmer Europe, southern Siberia, and northern China, and *H. fulva*, from the Levant. Both species, but particularly the latter, have been recommended as sources of green fodder for cattle.

**Dayton**, capital of Montgomery county, Ohio, sixth city of the state, is situated on the Great Miami, at the mouth of the Mad River, 48 miles NNE. of Cincinnati. The streets are broad, the private residences generally handsome; the public buildings include a court-house of white marble, a large jail, a number of schools, and many churches. Standing on the line of the Miami Canal (opened 1829), the city is the terminus of eight railroads, and the water of the Mad River is brought through its streets by an hydraulic canal,

supplying abundant water-power. It has paper-mills, manufactures of railroad cars, aeroplanes, agricultural machinery, &c. The National Cash Register factory is a very important institution. A tornado, fire and flood, in March 1913 proved very destructive to life and property. Pop. (1870) 30,473; (1890) 61,220; (1900) 85,333; (1910) 116,577; (1920) 152,559.

**D'Azara, FELIX** (1746–1811), born in Aragon, was a commissioner for delimiting the Spanish and Portuguese possessions in South America. He wrote a *Natural History of the Quadrupeds of Paraguay* (1801; trans. 1838), and *Voyages dans l'Amérique Méridionale* (1809).

**D'Azeglio.** See AZEGLIO.

**Deacon**, lit. a 'servant' or 'follower' (and, in that sense, found in classic and also in Hellenistic Greek), became in ecclesiastical usage the name for an office-bearer in the Christian church. In Acts vi. we read of the appointment of seven men chosen by the laity and ordained by the apostles to attend to the finances of the infant church, and to see that its alms are fairly distributed. The name deacon is not applied to them. They are to be spiritually-minded men; they are solemnly set apart from the rest of the congregation; and almost immediately they are found preaching and baptising (Acts, vi. vii. and viii. 38); and the most distinguished of them, St Stephen, dies as the first Christian martyr. In the epistle to the Philippians they are named along with the bishops, and in the pastoral epistles they are recognised as part of the Christian ministry (1 Tim. iii. 8–13) without any special reference to financial duties. Chrysostom suggested that the appointment in the Acts was of a temporary nature, and distinct from the sacred ministry of the diaconate subsequently instituted; and this view obtained some sanction from the sixth General Council. But a great Anglican antiquary, Bingham (supported in this matter by the Roman Catholics Thomassinus and Petavius), takes the opposite side, and is able to appeal to Justin Martyr, Irenæus, Hilary, Cyprian, and other doctors, to the effect that the seven were truly deacons in the later sense, and were authorised by the apostles to undertake these higher functions. The number seven continued to be adhered to in many churches—e.g. at Rome, until the 11th century, when the number was doubled.

During the 2d and 3d centuries, the duties falling to the deacons had considerably increased; and since as confidential attendants and helpers of the bishops, they had risen into consequence, it became necessary to divide the various functions among an arch-deacon, deacons, and sub-deacons. Deacons might now dispense the bread and wine at the communion, but not consecrate them. They had to receive the offerings and presents for the bishop, to keep the sacred vessels, to chant the introductory formulas of public worship, and to take the oversight of the morals of the congregation; and they were allowed, in many cases, with the leave of the bishop, to preach and baptise, and receive penitents into the communion of the church. At an early period, the offices of arch-deacon and deacon were considered to belong to the higher orders of consecration (*ordines majores*): this was not the case with that of sub-deacon till after the 12th century. At the consecration of a deacon, according to the Roman rite, certain sacred vessels may be handed to him as symbols of his office; but this does not seem to be regarded as essential. In the Greek rite the *flabellum* (a fan for driving away flies from the sacred elements) is given to the deacon. The peculiar robes are the dalmatica and the stole, but the stole (both in East and West) is only placed over the left shoulder.

In Protestant churches the position of deacons varies. Among Presbyterians, the elders have the spiritual oversight of the congregations; while deacons (as in the United Free Church of Scotland) and managers in others have the care of the financial affairs. Among Congregationalists, the deacons combine spiritual and financial duties. The Church of England has retained in the main the older form of ordination. The deacon has only the hands of the bishop laid upon him, and not those of any attendant priests also; he cannot consecrate the elements at holy communion or pronounce the absolution or benediction; and he only preaches by special license from the bishop, and not directly by virtue of his office. For this, as well as for holding any benefice or church-preference, priest's orders are necessary. The office is now regarded very much as simply one of probation before admission to priest's orders. But in ancient times it was not uncommon for a man to remain a deacon for life. The cardinal deacons at Rome sometimes remain such, especially if much occupied with secular business. Thus the late celebrated Cardinal Antonelli always remained a deacon. Before a person can be appointed deacon in the English Church, he must have reached the age of twenty-three, and he usually remains in this office one year at least.

DEACONESSSES (*ancillæ, ministræ, viduæ, virgines, episcopæ, presbyteræ*), female ministers or servants of the church or Christian society in the time of the apostles (Rom. xvi. 1). At a later period, they co-operated with the deacons, showed the women their place in the church assemblies, assisted at the baptism of persons of their own sex, instructed those who were about to be baptised as to the answers they should give to the baptismal questions, arranged the *agapæ* or love-feasts, and took care of the sick. In the 3d century it seems to have been also part of their duty to visit all Christian women who were suffering imprisonment, and to be hospitable to such as had come from afar. In very early times they were consecrated to their office by ordination in the same manner as other ecclesiastical or spiritual personages; later, however, they were inducted into their office by prayer without the imposition of hands. Until the 4th century, the deaconesses had to be either maidens or widows who had been only once married, and sixty years of age; but after the Council of Chalcedon the age was fixed at forty. Their assistants were called *sub-deaconesses*. After the 6th century in the Latin Church, and after the 12th century in the Greek Church, the office of deaconess was discontinued; but the former has retained the name. In convents, for example, the nuns who have the care of the altar are called deaconesses. In the Reformed Churches of the Continent there are deaconesses who nurse the sick and tend the poor. The first deaconesses' house at Kaiserswerth on the Rhine, near Düsseldorf, was founded by Pastor Fliedner in 1836; and now scattered over the Protestant world there are numerous similar institutions, with thousands of sisters. The Church of Scotland adopted the office of deaconess in 1887-88. The Diocesan Deaconess Institution, London, was established in 1861; but Sisterhoods (q.v.) have struck a much deeper root in the Anglican communion. See works by Dean Howson (1886) and Cecilia Robinson (1899).

**Deacon of a Trade**, the president, for the time being, of certain incorporations in Scotland, where, prior to the passing of the Burgh Reform Act, 1834, the deacons of trades or crafts represented the trades in the respective town-councils. That act enacted that the deacons shall no longer be recognised as official and constituent members of the town-council, but preserved the power of the crafts to elect deacons and other officers for the

management of their affairs. The deacon-convenor of the trades in Edinburgh and Glasgow is still a member of the town-council. See DEAN OF GUILD.

**Dead**, in *seafaring* language, is very frequently employed as part of a designation or phrase having, in general, a meaning somewhat opposite to that of *active, effective, or real*. The chief of such phrases are the following: *Dead-eyes*, circular, flattish wooden blocks, without sheaves, and having eyes for lanyards, which form a purchase or tackle whereby the shrouds or other fixed rigging are extended or set-up taut; *Dead-flat*, the name for one of the midship-timbers; *Dead-lights*, strong wooden shutters used to close cabin-windows, on the approach of a storm, to protect the glass; *Dead-ropes*, such as do not run in blocks; *Dead-wood* is the term applied to the solid blocks of timber eiected upon the keel throughout the sharp portions of a ship's hull at stem and stern, the chief object being to give solidity and strength to the ends of the ship; *Dead-reckoning*, an estimation of a ship's place without celestial observations, made chiefly by the log-book, and liable to error on account of currents, lee-way, fluctuation of wind, &c. To these may be added *Dead-wind*, a seaman's designation for a wind blowing directly against a ship's course.

Other compounds are *Dead-lock*, a position of matters when they have become so complicated that they are at a complete standstill and progress is impossible; *Dead-freight*, the compensation paid to the shipmaster by the merchant who freights a whole ship for the space which he fails to occupy; *Dead language*, one no longer spoken; and *Dead-letter*, a letter undelivered and unclaimed at the Post-office (q.v.). The *Dead-points* of an engine are when the connecting-rod and the crank are in one line (see CRANK). The impetus of the fly-wheel is necessary to carry the engine over these points, and if it is allowed to stand at either of them, a start is impossible till the fly-wheel is turned by hand sufficiently to permit of the piston acting on the crank.

**Dead, BOOK OF THE**, the great funerary work of the ancient Egyptians, who themselves entitled it *Per-em-Hru*, 'to go forth from (or by) day.' It is 'a collection of prayers and exorcisms composed at various periods for the benefit of the pilgrim-soul in his journey through Amenti (the Egyptian Hades); and it was in order to provide him with a safe-conduct through the perils of that terrible valley that copies of the work, or portions of it, were buried with the mummy in his tomb.' Such copies, hieroglyphic or hieratic according to the age when they were executed, and made some to order, others for sale, constitute fully one-half of the thousands of extant papyri. They are mostly corrupt and faulty; but as the fruit of ten years' toil, a critical text was at last published by Edouard Naville in *Das Aegyptische Todtenbuch der XVIII. bis XX. Dynastie* (Berlin, 1886), whose folio supplement contains 212 plates of texts, vignettes, and variants of vignettes. Dr Birch's English translation (*Egypt's Place in Universal History*, vol. v. 1867) is based on Lepsius' imperfect Turin text (1842), as also is Pierret's French translation (1882). See the articles EGYPT, HIEROGLYPHICS, and AMENTHES; texts, facsimiles, translations, &c., by Sir E. A. Wallis Budge (1895-1913); and a masterly article by Miss A. B. Edwards in the *Academy* for 10th September 1887.

**Dead, PRAYER FOR THE**. See PRAYER, PURGATORY, REQUIEM.

**Deadly Nightshade**. See BELLADONNA.

**Dead-men's Fingers**. See ALCYONIUM.

**Dead Nettle** (*Lamium*), a genus of Labiatae. *L. purpureum* and *L. album*, together with (Gale-

opsis) the closely allied common British weeds.

White Dead Nettle  
(*Lamium album*).

Hemp-nettle, are very common. The commoner species have been somewhat thoroughly naturalised in the long-settled parts of the United States. They are sometimes boiled as pot-herbs in Sweden. The name seems derived from the superficial resemblance to the true or stinging nettles; this is especially marked in *L. album*.

**Dead Sea** is the usual name, dating from the time of Jerome, for a most remarkable lake in the south-east of Palestine, called in the Old Testament *The Salt Sea*, *Sea of the Plain*, or *East Sea*; by Josephus, *Lacus Asphaltites*; and by the Arabs now, *Bahr-Lūt*, 'Sea of Lot.' It is 46 miles long, with a

breadth of from 5 to 9 miles. Its surface, which is lower than that of any water known, is 1292 feet below the level of the Mediterranean. The depth of the greater part, the northern section is about 1300 feet; but at the southern end the water is only from 3 to 12 feet deep. The shape is that of an elongated oval, interrupted by a promontory which projects into it from the south-east. The Dead Sea is fed by the Jordan from the north, and by many other streams, but has no apparent outlet, its superfluous water being supposed to be entirely carried off by evaporation. Along the eastern and western borders of the Dead Sea there are lines of bold, and in some cases perpendicular, cliffs rising in general to an elevation of 1500 feet on the west, and 2500 feet on the east. These cliffs are chiefly composed of limestone, and are destitute of vegetation save in the ravines traversed by fresh-water streamlets. The north shores of the lake form an extensive and desolate muddy flat, marked by the blackened trunks and branches of trees, strewn about and incrustured with salt. The southern shore is low, level, and marshy, desolate, and dreary. On this shore is the remarkable ridge of rock-salt, 7 miles long and 300 feet high, called *Khashm Usdom* ('Ridge of Sodom'). Lava-beds, pumice-stone, warm springs, sulphur, and volcanic slag prove the presence here of volcanic agencies at some period. The neighbourhood of the Dead Sea is frequently visited by earthquakes, and the lake still occasionally casts up to its surface large masses of asphalt. The basin of the sea and the valley of the Jordan seem both to be due to a great fault or crack in the earth's surface of very ancient date. The long-entertained belief that the exhalations from this lake were fatal is not founded upon fact. Within the thickets of tamarisk and oleander, which here and there may be seen upon its brink, the birds sing sweetly, and they fly over and swim about on its surface. But the salinity of the waters is adverse to life, though some lower organisations are found in them.

The water of the Dead Sea is characterised by the presence of a large quantity of magnesian and soda salts. Its average specific gravity is about 1166 (pure water being 1000). The proportion of saline matter is so great that, whilst sea-water contains only 3.5 per cent. of salts, the water of the Dead Sea contains upwards of 26 per cent., or more than seven times as much as that of the ocean. In all

lakes or collections of water without any outflow, the water acquires an infusion of salt from its feeders, while none can go off by evaporation, even when the shores do not as here abound in salt and nitre. The principal salts in the water are chloride of calcium, magnesium, sodium, and potassium, with bromides and sulphates of the same. The evaporation is great as the heat is intense, and the sea rather contracts than increases. Rain hardly ever falls; the water is nearly as blue and clear as that of the Mediterranean; and though it is very hurtful to the eyes, and though it is horribly salt and ill-smelling, a bath in it is refreshing. Owing to the great specific gravity of the water, it is almost impossible for the bather to sink in it. The geological fault in which the Dead Sea and the Jordan valley lie dates probably from the end of the Eocene period; the site of the 'cities of the plain' cannot accordingly be beneath the present sea, as used always to be assumed (see SODOM AND GOMORRAH).—**DEAD SEA APPLES**, or Apples of Sodom, described by Josephus as 'externally of fair appearance, but turning to smoke and ashes when plucked by the hands,' cannot be the *Solanum sodomæum* (see SOLANUM), which botanists call 'Apple of Sodom.' Seetzen, Irby, Mangles, and Robinson identify them with the fruit of *Asclepias gigantea vel procera* (a tree 15 feet high), like a large smooth orange or apple. Being filled mainly with air, the ripe fruit, when pressed or struck, explodes with a puff, leaving in the hand, except fragments of rind and a few fibres, only a central pod, containing, with the seed, a little fine silk, which the Arabs twist into gun-match.

See books quoted at PALESTINE; De Sauley (1853) and the Duc de Luynes (1874) on the Dead Sea; the *Jewish Encyclopedia*; and German works by Tuch (1863), Fraas (1867), and Blanckenhorn (1912).

**Dead's Part**, in Scots law, is that part of a man's movable property which he is entitled to dispose of by testament. If a man dies without leaving widow or children, the dead's part is the whole; if he leave widow but no children, or children but no widow, it is a half; and if he leave both widow and children, it is a third of his movable property. The dead's part may be increased or diminished by marriage-contract, or by wife and children renouncing their legal rights.

**Deaf and Dumb.** Persons who are born deaf, or who lose their hearing in infancy, are dumb also; hence the compound term deaf-and-dumb. But deafness is the primary defect; dumbness is only the consequence of deafness. Normal children hear sounds, and then learn to imitate them; i.e. they learn to repeat what they hear other persons say. It is thus that every one of us has learned to speak. But because the deaf child hears nothing it cannot imitate, and therefore remains dumb. Persons who lose their hearing later in life are not to be classed among the deaf and dumb. Having acquired speech before their hearing was lost, they can still retain that means of communication with others; and if they are educated, there are open to them all the stores of knowledge contained in books, from which the juvenile deaf and dumb, ignorant of all written and spoken language, are utterly excluded. It is this latter class alone which was contemplated in our census enumerations, and for which our institutions for the education of the deaf and dumb were designed.

The term 'deaf and dumb' is somewhat unfortunate, as embodying and repeating the error that the affliction is twofold. It affects two organs, certainly, but only, as above described, in the way of cause and effect. The organ of hearing is wanting, but the organs of speech are present; they merely lack the means of exercise. The ear is the guide and directress of the tongue; and when the ear is doomed

to perpetual silence, the tongue is included in the ban; though, if we could by any means give to the ear the faculty of hearing, the tongue would learn for itself to fulfil its proper office. To correct the error involved in this apparent misnomer, some authorities use the term *deaf* simply, others speak of the *deaf-dumb* and *deaf-mute*. The latter term is common in America, as in France is its equivalent *sourds-muets*. In the Holy Scriptures the same original word is translated 'deaf' in some places (as in Mark, vii. 32), and 'dumb' or 'speechless' in others (see Matt. ix. 33, and Luke, i. 22).

Deaf and dumb persons may be classified under two main heads—viz. (1) the 'congenital' or born deaf, and (2) the 'adventitious deaf,' or those who have lost hearing after birth. Consanguinity of parents has been adduced as a probable cause of a deaf offspring. Among the diseases conducive to post-natal deafness are cerebro-spinal meningitis and other inflammatory diseases of the brain and its membranes, scarlet fever, measles, scrofula, and diphtheria; while children also have become deaf from falls or from teething.

This affliction is very much more common than, for a long time, it was supposed to be. Happily, however, along with the knowledge of its extensive prevalence, has come the means of alleviating it, by education. It was only when the schools now in existence began their useful work, and caused inquiries to be made, that the actual numbers of the deaf and dumb began to appear. In places where it was proposed to establish a school—in Paris, London, Liverpool, Manchester, Yorkshire, and in New York—the objection was immediately raised that children could not be found in sufficient numbers to require such schools. Their promoters, however, knew better than this, and persisted in their design. They soon had the satisfaction of converting the objectors into their warmest supporters. The facts thus ascertained, and the calculations based upon them, continued to be the only statistics upon the subject of deaf-dumbness in Great Britain and Ireland until the census of 1851, when for the first time the number and ages of the deaf and dumb formed a part of the inquiry.

The deaf are spoken of frequently in the writings both of the Old and New Testaments; they are alluded to by the poets, philosophers, and lawgivers of antiquity; yet we have no account of any attempt at educating them until the 15th century; no school existed for them until the middle of the 18th; nor could it be said that education was freely offered, and readily accessible, until the middle of the 19th century.

Some isolated attempts had been made before the 18th century, by different men, in different countries, and at long intervals, to give instruction to one or two deaf and dumb persons, and their endeavours were attended with various degrees of success. These several cases excited some attention at the time; but after the wonder at their novelty had subsided they seem to have been almost forgotten, even in the countries where the experiments were made. Bede speaks of a dumb youth being taught by St John of Beverley (q.v.) to repeat after him letters and syllables, and then some words and sentences. The result was regarded as a miracle, and was classed with others alleged to have been wrought by the same hand. From this time, eight centuries elapsed before any record is given of an instructed deaf-mute. Rodolphus Agricola, a native of Groningen, born in 1442, mentions as within his knowledge the fact that a deaf-mute had been taught to write, and to note down his thoughts. Fifty years afterwards this statement was controverted, and the alleged fact pronounced to be impossible, on the ground that no instruction could be conveyed to the mind of any

one who could not hear words addressed to the ear. But the discovery which was to give the key to this long-concealed mystery was now at hand. In 1501 was born, at Pavia, Jerome Cardan (q.v.), a man of great but ill-regulated talents, who, among the numerous speculations to which his restless mind prompted him, certainly discovered the theoretical principle upon which the instruction of the deaf and dumb is founded. He says: 'Writing is associated with speech, and speech with thought; but written characters and ideas may be connected together *without* the intervention of sounds,' and he argues that, on this principle, 'the instruction of the deaf and dumb, though difficult, is *possible*.' All this, which to us is obvious and familiar, was a novel speculation in the 16th century. It is quite possible for a man to teach himself to read a language, though he cannot speak it, because he has not heard the words pronounced. In fact many persons do acquire this art. It is evident, therefore, that written or printed words do impart ideas independently of sounds, yet this was a discovery which the world owes to Jerome Cardan; and it was for want of seeing this truth that the education of the deaf and dumb was never attempted, but was considered for so many centuries to be a thing impossible.

It was in Spain that these principles were first put into practice by Pedro Ponce (1520–84), a Benedictine monk, and again, in the following century, by another monk of the same order, Juan Paulo Bonet, who also published a work upon the subject. This record of experience was the means of instructing other teachers, and constituted the first step towards making the education of the deaf and dumb permanent. Bonet's book, published in 1620, was of service to De l'Épée, a hundred and forty years later; and it contains, besides much valuable information, a manual alphabet identical in the main with that one-handed alphabet which is now in use in schools on the Continent and in America. His own system of teaching, however, like that of every teacher in every country before De l'Épée, was in the main *oral*. The practicability and adaptability of *signs*, for conversation rather than teaching, had occurred to several of the earlier teachers, but De l'Épée was the first to adopt them as a distinct medium, and the chief medium, of teaching, and so to establish them as a language. Bonet himself says of the manual and written alphabets that they 'should be associated with speech, by pointing to the letter as written with the finger corresponding with the same letter in the manual alphabet and the articulated sound.' He also describes the positions and movements of the vocal organs necessary in pronunciation, as he himself used them, and as, with little variation, Wallis and Amman also in later times used them, believing themselves to have been the original inventors of the methods they employed. From the time of Bonet there was a general awakening of the attention of intellectual men, not only to the importance of the subject, but to the practicability of instructing the deaf-mute. One of Bonet's pupils was seen by Charles I., when Prince of Wales; and the case is described by Sir Kenelm Digby, who met the prince in Madrid during his memorable matrimonial journey to Spain (1623). Of this pupil, a younger brother of the Constable of Castile, Sir Kenelm gives an interesting account in his *Treatise of Bodies*, how he 'would repeat after anybody any hard word whatever'—not Spanish merely, but English, and even Welsh.

When the art died away in Spain it was taken up by Englishmen, and began forthwith to assume an entirely new aspect. Dr John Bulwer published in 1648 his *Philosophus, or the Deafe and Dumbe Man's Friend*, in which he speaks of a 'lip-grammar,

which may enable you to hear with your eye, and thence learn to speak with your tongue.' Bonet also found in the course of his experience that lip-reading reached a much greater utility than he had, at the outset, thought it capable of. Dr William Holder published his *Elements of Speech, with an Appendix concerning Persons Deaf and Dumb*, in 1669; and Dr John Wallis, Savilian Professor of Mathematics in the university of Oxford, taught the deaf and dumb with great success, and also wrote copiously upon the subject. In 1662 one of the most proficient of his pupils was exhibited before the Royal Society, and in the presence of the king. The *Philosophical Transactions* of 1670 contain a description of his mode of instruction, which was destined to bear good fruits long after his death.

Before the close of the 17th century many works of considerable merit appeared, the chief of which are the *Surdus Loquens* (1692) of John Conrad Amman, a physician of Haarlem; and the *Didascalocophus, or Deaf and Dumb Man's Tutor*, of George Dalgarno (q.v.). This treatise, published in 1680, and reprinted in 1834 by the Maitland Club, is eminently sound and practical, which is the more remarkable, as the author speaks of it as being, for aught he knows, the first that had been written on the subject. He is the first English writer who gives a manual alphabet. The one described by him, of which he was the inventor, is, most probably, that from which the present two-handed alphabet is derived. Henry Baker (q.v.) about 1720 introduced an improved system of his own; in 1765 the Abbé de l'Épée established his little school in Paris; and five years previously the first school in Great Britain had been started in Edinburgh by Thomas Braidwood (q.v.). He commenced with one pupil, the son of a merchant in Leith, who had strongly urged him to carry into effect the plan of instruction followed by Dr Wallis, and described in the *Philosophical Transactions* ninety years before. His school, the parent and model of the earlier British institutions, was visited and described by many of the influential men of that day, and its history and associations are imperishable. Its local name of 'Dumbiedykes' suggested to Sir Walter Scott a designation for one of his most popular characters in the *Heart of Midlothian*. A visit paid to it in 1773 by Dr Johnson and his biographer Boswell supplies one of the most suggestive and characteristic passages in the *Journey to the Western Islands*, in which he speaks of Henry Baker and his unpublished work. In 1783 Braidwood removed to Hackney, near London, and the presence of his establishment so near to the metropolis undoubtedly led to the foundation of the London Asylum in 1792. Dr Watson, its first principal, was a nephew, and had been an assistant, of Braidwood; and he states that, some ten or fifteen years previously, the necessity for the establishment of a public institution had been plainly seen, and some few but insufficient steps taken towards the accomplishment of such a design. From its foundation in 1792 until 1829 it was directed with great ability by Dr Joseph Watson, author of *Instruction of the Deaf and Dumb*.

It is to the 19th century that the honourable distinction belongs of having done much for the deaf and dumb. This has not been by inventing the art of teaching, or by raising up the earliest labourers in this field of usefulness, but by founding and supporting public institutions for this purpose. De l'Épée, when he opened his school in 1765, had no foreknowledge of the work he was commencing. As his labours increased he invited others to his assistance, and they were thus enabled to carry the light of instruction elsewhere, and to keep it

alive when he was no more. His death took place in 1789, and his assistant, Sicard, succeeded him. Four years afterwards the school was taken over by the French government, and now exists as the Institution Nationale of Paris. A pupil of this institution, M. Laurent Clerc, went in 1816 to the United States with Mr Thomas Hopkins Gallaudet (1787-1851), the founder and first principal of the American Asylum, who in the New World became, like De l'Épée, 'the father of the deaf and dumb.'

The mental condition of the deaf and dumb is so peculiar—so entirely unlike that of any other branch of the human family—that it is extremely difficult, without very close thought, to obtain an accurate conception of it. While almost every one will readily admit that there is a wide difference between a deaf and a hearing child, very few, who have not had their attention specially drawn to the subject, possess any adequate notion of the difference, or could tell wherein it consists. Sometimes the deaf are compared with the blind, though there exists no proper ground of comparison between them. Except that the blind are more dependent than the deaf and dumb, the relative disadvantages of the two classes do not admit of a moment's comparison. The blind child can be talked with and read to, and thus acquire language on natural lines. He is thus placed in direct intercourse with the world around him; domestic converse, literary pleasures, political excitement, intellectual research are all eventually within his reach. But the born-deaf child is utterly excluded from the early training which leads to such a standard of mental development. The two afflictions are so essentially dissimilar that they can only be considered and spoken of together by way of contrast. Each of them affects both the physical and the mental constitution; but blindness, which is a greater physical affliction, falls less severely on the mind; while the effect of deafness is the extreme reverse of this—it touches only one bodily organ, and that not visibly, but the calamity which befalls the mind is one of the most desperate in 'the catalogue of human woes.' The deprivation under which the born-deaf labour is not merely, or so much, the exclusion of sound. It is, as already indicated, the complete exclusion of all that information and instruction which are conveyed to our minds, and all the ideas which are suggested to them, by means of sound; as it is through sound alone, in the first instance, that we all learn language, the medium of all knowledge. Since speech tells the deaf nothing, because they cannot hear, and books teach them nothing, because they cannot read, their original condition is far worse than that of persons who 'can neither read nor write' (one of our most common expressions for extreme ignorance); it is that of persons who can neither read, nor write, nor hear, nor speak.

It is not to be assumed, however, that before the deaf child comes under instruction he knows practically nothing, or that his mind is a complete blank. Through his remaining senses—and particularly through sight—he has acquired a certain knowledge of things which, to some extent, has exercised his reasoning faculties and enabled him to form ideas. But he has no word symbols by which he may name and have recalled to his imagination the many wonderful objects and acts he sees around him. His curiosity may often be aroused, but he cannot ask the many interesting questions we hear from little children.

At the outset of his school career the deaf-mute is handicapped not only by an entire absence of the vernacular, but by a want of any means of word expression. Two outstanding methods are now employed in the education of deaf-mute children—viz. the oral and the manual alphabet. As

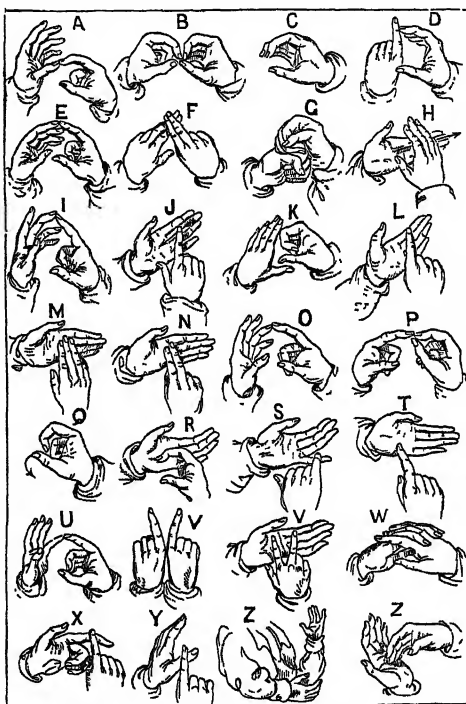

the name implies, the oral method seeks to teach by speech and lip-reading. To give the deaf and dumb speech was long considered an impossible task; and when in some cases success did accompany the effort, the result was looked upon as little short of a miracle. It is possible that this opinion arose from a misconception that dumbness accompanied and permanently remained with deafness. But when it is considered that the emotional cry of the deaf child closely resembles that of the normal, and that he can be induced to babble like an infant, it may readily be conceived how articulate speech can be evolved from such a source. To gain a sense means of reproducing sound the pupil can be led to feel the vibrations by placing the hand on the thorax. The course of instruction may proceed through the various sounds as represented by the letters of the alphabet, the phonetic value being taught—not the name of the letter. The order of presenting these symbols varies to some extent in different countries and schools; but in all the principle prevails of proceeding from the simple to the difficult, regard being had to the ability of perception by the pupil, and the muscular effort required in producing the sound. Although the child is encouraged to learn mainly by imitation, the teacher may require to place the speech-organs in position; while long and continuous practice is necessary before any degree of muscular facility is apparent. As the course progresses, the syllabic combination of sounds leads to the spoken word and sentence, while attention is also paid to the development of accent, emphasis, intonation, and fluency of speech.

Since imitation is the governing principle required of the deaf child in learning speech, his eye is being constantly trained to observe the various positions assumed by the vocal organs, and from this experience there follows the ability to lip-read. Whilst the greatest amount of movement occurs in the labial region, other parts of the face also indicate vocal expression; and the art, therefore, may be termed more correctly speech-reading. But speech-reading does not become a perfect substitute for hearing. It requires favourable conditions with regard to position of speaker and direction of light. And while groups of our language sounds, as *p*, *b*, *m*, show no appreciable variation in position of the vocal organs, the gutturals and nasals, *k*, *g*, *ng*, give little or no visible indication of their utterance. Thus the eye finds it difficult to distinguish such sound elements. When, however, the pupil has gained a knowledge of language, he is able to a large extent to overcome this difficulty by an intelligent inference of the required term in agreement with the context of the matter which is being communicated.

Early attempts at oral instruction were sporadic. The first organised effort to make the method universal in schools was initiated in 1773 by Heinicke of Germany, and thus it has come to be known also as the 'German system.' After the international congress at Milan in 1880—where the oral method became the chief topic of discussion—it was adopted in many countries of the Continent, and its influence was felt in an extension of the movement in schools in the United Kingdom and America. In 1886 the education of the deaf and dumb was made a subject of investigation by a royal commission, whose report was issued three years later. From the voluminous evidence obtained, the commissioners recommended that all deaf and dumb children should be given opportunity of instruction by the oral method. Authorities recognise the justice of this claim. Deafness among the so-called 'born deaf' is a matter of degree; while many children who enter the special schools come from the class of 'adven-

titious deaf,' and have more or less residual hearing or speech, or both. Success in the oral instruction of the 'born deaf' varies according to the ability—physical or mental—of the pupil; but it is recognised as a duty to exercise the remaining speech and hearing of deaf children to the fullest extent. Mention might be made here of a subsidiary method, the auricular, by which the residual hearing is more particularly used for general instruction.

The manual alphabet method may be described as writing in the air by means of the hands. As a medium it is not employed to supersede script or print, but is used conjointly with writing in an association similar to that of writing and articulate speech. There are two forms of the manual alphabet, the single-handed and the two-handed. While the former is used in schools in America,

Two-handed Alphabet.

the continent of Europe, and some parts of Ireland, the latter is preferred by teachers in Great Britain, possibly because of its closer resemblance in form to most of the letters of the script and printed alphabets. Educational authorities differ in the selection of methods. In many schools the oral only is practised; in others a combination of both is in use under the designation the 'combined system.' It may be claimed for finger-spelling (the manual alphabet) that, contrasted with speech-reading, it forms an easier medium of communication with the deaf child, because the eye can perceive every detail of symbol presented to it. Many teachers, therefore, hold that, in the early stages of language instruction, more progress is effected by a use of finger-spelling than by a rigid adherence to speech and speech-reading.

The development of language is the governing factor in the education of the deaf and dumb child. His greatest misfortune is the loss of that training during the invaluable plastic pre-school period of life, when the mind of the normal child is so highly

impressionable, his vocabulary so spontaneously acquired, and his imagination so pleasurably exercised. That is the period of the 'mother's method.' Early attempts at teaching language were generally on grammatical lines. De l'Épée endeavoured to establish the vernacular by translation through a system of natural gestures and arbitrary or conventional signs. But by this procedure the sign, instead of the word, remains the vehicle of thought. Teachers, therefore, condemn any systematic use of conventional signs. Since the school-period of the deaf child in the United Kingdom is limited to nine or eleven years, it is found necessary to accelerate progress in the acquisition of language in order that the pupil may approximate to a normal standard of primary education; and although exercises on grammatical lines are found serviceable, modern opinion recognises the necessity of conforming as closely as possible to the natural processes of acquiring language. In the initial stages a vocabulary is built up by directly associating objects and acts with their names. The object is shown, or the act performed, and the word is spoken or finger-spelled, and written. Pictures are used to give representations outside the scope of a schoolroom. The natural gestures which the little deaf child has used at home are at first recognised as serviceable, but are dispensed with as soon as practicable. Language development gradually proceeds through simple to more difficult sentence structure, introducing idioms, metaphors, and figures of speech. During this course the conversational or colloquial form of expression predominates, because *prima facie* deaf children must be led to recognise the practical value of words as a means of communication with one another. The literary side of language is not ignored, however. Reading exercises are given; books are supplied; and the pupil is encouraged to gain that command of literature which will lead to his self-development as an intelligent and useful unit of the community.

Until the close of the 19th century the work of educating deaf and dumb children was almost wholly dependent on charity. In 1890 there became law the Education of Blind and Deaf Mute Children (Scotland) Act, and in 1893 an act of a similar nature was passed for England. These measures made compulsory the education of deaf-mute children between the ages of seven and sixteen years; and upon School Boards devolved the duty of carrying out the prescribed conditions, which include the payment of moneys from public rates. An efficient elementary education is now required; the schools are reported upon by his Majesty's inspectors, and grants made by the Education Departments.

At the dates above no provision was made for the training of teachers of deaf children. The only movement to establish a standard of professional attainment emanated from the teachers themselves. In 1884 a college was incorporated in London, and a body formed, which comprised the most experienced teachers. This college annually granted diplomas to candidates who passed the following specific test set by the examiners: *Subjects*.—(1) History of the Education of the Deaf and Dumb. (2) The Principles of Education. (3) Intuitive Method of Teaching Elementary Language. (4) Method of Teaching Advanced Language. (5) Practical Instruction of a Class. (6) The Mechanism of Speech with the Anatomy and Physiology of the Organs. (7) The Method of Teaching Articulation.

Two other colleges were formed in London, each granting a diploma similar to the above-mentioned; but the three ultimately combined, and issued a form of certificate approved by the Board of Edu-

cation (England). In the Regulations put in force by the Education Departments of England and Scotland the authorities have provided for the special training and qualification of teachers of the deaf. This training can now be taken at the Victoria University of Manchester. While it is highly desirable that the teacher should be conversant with the principles and methods employed in the education of normal children, a longer, closer, and more intimate study of the deaf is necessary before he can hope fully to grasp the particular educational needs of his pupils.

The first institution in Great Britain was founded at Old Kent Road, London, in 1792—it is now located at Margate; the next in England was that at Edgbaston, Birmingham, in 1812. The Edinburgh Royal Institution dating from 1810, the Glasgow and the Aberdeen Institution from 1819, the Claremont School in Dublin founded in 1816, and the Belfast Institute in 1831 are the earliest in Scotland and Ireland. Donaldson's Hospital (Edinburgh), opened in 1850, is unique in having both normal and deaf children boarded and educated in the one institution. Although the two classes receive instruction in separate rooms, they associate freely in their games and social events. In Denmark is found the most consistent attempt at a scientific classification of deaf and dumb children for the purpose of education. In this small European state, with a population of over three millions, the number of deaf-mute children under instruction is about 400. After attendance for one year at a preparatory school in Fredericia the children are classified on the bases of residual hearing and speech, and mentality. Each class is educated at different schools—one at Fredericia, another at Nyborg, and another at Copenhagen; and, with the exception of the totally deaf of dull intellect, the oral method only is used. Preparatory schools for very young deaf children have been established in America and Great Britain. At the Bala, Philadelphia School, the little ones are admitted at ages ranging from two to seven years. While instruction proceeds on lines analogous to the kindergarten, the aim of the teacher is to enable the pupils ultimately to enter schools for the hearing. The value of such early training is evident. But authorities maintain that the latter course is not the best for the deaf child, because in a normal school he will not obtain that attention necessary to ensure his highest mental development.

During recent years the desire has been evinced for a closer co-operation between the medical and the teaching profession of the United Kingdom with a view to a more scientific classification of deaf children. A step in this direction was the opening by the Glasgow School Board in 1908 of a day-class for semi-deaf and semi-mute children. The oral method only is employed; and the pupils, during the school-day, have no opportunity whatever of associating with those who use 'signs' or finger-spelling.

The education of deaf and dumb children is now carried on in day schools as well as in institutions or boarding schools; and there exists much diversity of opinion which of these better serves the needs of the pupils. The advantages claimed for the institution system are: (1) that the deaf, being an abnormal class of children, and therefore requiring more continuous teaching and maintenance of discipline, are better provided for in institutions, where they are continually under the supervision of trained instructors; (2) that as many of the deaf come from poor homes where medical attendance and regularity and quality of diet are at a minimum, they receive in the institutions the care and attention necessary for the healthy

development of body and mind; (3) that the institution is more fully equipped for physical and industrial training; and (4) that the deaf, being such a widely scattered population, require to be brought to centres in order to admit of proper grading and to ensure regularity of attendance. In fact, many authorities are of opinion that special institutions are a necessity for the great mass of deaf children. On the other hand, advocates of the day-school system claim: (1) that the pupils attending day-classes are not subjected to the dull routine which, they maintain, is characteristic of institution life, and have, by reason of their going to and returning from school, and mixing with friends, a greater variety of topics for the building up and exercise of language; (2) that the pupils can live at home and benefit by home influence; and (3) that home-ties are not weakened.

Day-classes are conducted in several of our large cities where travelling facilities are convenient, and where the number of children in and around their immediate vicinities admits of several classes being formed. In London, where the day-classes are under the County Council, the children go to and return from school under the care of responsible guides or relatives—all travelling expenses incurred being met by the Council. At the age of thirteen these children are transferred to semi-residential schools in the suburbs—Anerley (for boys) and Oak Lodge (for girls). Here, in well-equipped workshops, and under trained instructors, the pupils devote part of the day to industrial pursuits.

In many of the large manufacturing centres of the United Kingdom societies exist for the advancement of the social and religious interests of the adult deaf and dumb. These agencies are ably organised by missionaries, many of whom have been teachers. Through the generosity of a Mr Leo. Bonn there was established in 1911 in London the 'National Bureau for Promoting the Welfare of the Deaf.' While the majority of deaf people find employment in bootmaking, tailoring, dress-making, and domestic service, occupation is also found for them in pursuits such as those connected with agriculture, with wood, with metals, with machinery, and with art-work. Handicapped as they are in having comparatively few industries open to them, their difficulties have been increased by legislative enactment, such as the Workmen's Compensation Act, in which the condition of insurance tends to their disadvantage.

In the United States of America more considerate measures prevail. The institutions are supported by generous grants from each state, and the school course of the pupil extends to his twentieth year. At Washington the deaf student can enter the college established in 1864 under the presidency of the late Dr E. M. Gallaudet, the youngest son of the founder of the American 'Asylum.' Such educational privileges enable deaf persons to enlarge their spheres of usefulness, even to holding positions in government departments of the republic.

**DEAF AND DUMB, in Law.** The Roman law held deaf and dumb persons to be incapable of consent, and consequently unable to enter into a legal obligation or contract. Both in England and Scotland they may make contracts or wills if they have the use of reason and understand the nature of their undertaking, and express their consent intelligibly. Although the presumption of law is that a deaf and dumb person is in the same state as an idiot, and

incapable of any understanding, such a one may be subjected to a criminal trial on proof that he knows right from wrong. And, if he understands the nature of an oath, and is possessed of intelligence, he may give evidence as a witness by signs through an interpreter or by writing. It is always a good objection to a jurymen that he is deaf and dumb.

In the United States, in general, the legal presumption of the common law as to the mental incapacity of the deaf and dumb does not exist. They are presumed to be capable of comprehending the nature of crime, the nature and obligation of an oath, and of making any contract; hence they may be indicted, tried, and punished for crime, and may testify as witnesses. The federal courts have no peculiar jurisdiction over persons deaf and dumb, but the act of congress prescribing punishment to be inflicted upon 'every person' who is guilty of certain acts prohibited includes every person possessed of sufficient mental capacity for criminal responsibility, although he or she may be deaf and dumb. The federal courts are governed by the practice of the states in which the cause is pending as to the competency of a deaf and dumb person as a witness, and this competency will be determined in either state or federal court by the judge before whom the cause is pending, upon examination of the individual, and upon testimony of those acquainted with the party. A deaf and dumb person is legally incapacitated to serve as a juror, or for service in the army and navy, but in other respects has the rights of citizenship.

#### Deafness. See EAR, DISEASES OF.

**Deák, FRANCIS**, Hungarian politician, was born in 1803 at Kehida, in the district of Szalad, where, after a course of legal study at Raab, he practised as an advocate, until returned as its representative to the national diet in 1832. He soon took his place as leader of the liberal opposition, and by his firm and moderate policy effected reconciliations between Hungary and the Austrian emperor as her king—temporarily in 1840, and more permanently in 1867. After the revolution of March 1848 he became Minister of Justice in the cabinet of Count Batthyányi, and made every effort to ward off the inevitable war. On Kossuth's coming into power (September 1848), Deák resigned his portfolio, and after the unsuccessful attempt next year at negotiation, withdrew from public affairs, and retired to his estate. He refused to return to public life till 1860, when a constitution was granted to his country.

Returned by Pesth to the diet in 1861, he again became the leader of the moderate party, while the extreme party collected round Count Téli. The death of the latter (8th May) destroyed the only influence which could counterbalance that of Deák; and the diet appointed him to draw up the address to the emperor demanding the constitution of 1848, a Hungarian ministry resident in Pesth, the return, without restriction, of the exiles, and the restitution of their property. The emperor answered it by a hostile rescript, against which Deák protested strongly. Out of the humiliation of Austria in 1866 came the triumph of Deák's policy. He asked nothing more than before, and thus his wise and statesman-like moderation effected a satisfactory constitutional relation between Austria and Hungary in the dual system of monarchy. Deák's party was all-powerful, but he lived to see the rise of a more advanced party under the leadership of Tisza. He died at Budapest, 29th January 1876. See Memoir, with preface by Grant-Duff (1880).

**Deakin, ALFRED**, politician and publicist, born in Melbourne, Australia, in 1856, entered the Victorian parliament in 1879, in 1883 became

minister of public works and water supply, and in 1886 succeeded Sir Graham Berry as leader of the liberal section of a coalition government which ruled the colony till 1890. His most important work during this period was the establishment in Victoria of an extensive irrigation system, in connection with which he visited Egypt, Italy, and India. He next interested himself ardently in the cause of Australian federation, representing his colony not only at the conferences of 1890-91, but also on the Federal Council in 1889, 1895, and 1897, and taking a prominent part in the convention of 1897-98, which framed the federal constitution; and he was one of the delegation from Australia which safeguarded the passage of the Constitution Act through the imperial parliament in 1900. He sat in the federal parliament from its inception to 1913 as member for Ballarat, being Attorney-general in Sir E. Barton's ministry from 1901 to 1903, and Prime-minister in 1903-4, 1905-8, and 1909-10; in 1913 he retired into private life, though in 1914 he accepted the position of Australian commissioner to the San Francisco exhibition. Apart from his work as a pioneer of irrigation methods in Australia, his enduring reputation will rest on his career in federal politics. For the Commonwealth's first ten years he was the originator or inspirer of every important measure or development of policy save one. The compulsory principle in military training he accepted half-heartedly from others; but the bases of Australian naval defence, fiscal policy (including British preference), financial relations between States and Commonwealth, immigration policy (as regards federal action), external (with respect to the islands of the western Pacific) and territorial (Papua and the Northern Territory) policy were all laid by him. In none of his prime-ministerships had he an independent majority; but, whether in or out of office, whether allied with the Labour party or with their bitterest opponents, his only terms of alliance were the acceptance of his programme, which his successors are still engaged in carrying out. His visit to London in 1907, as representative of Australia at the Imperial Conference, set him among the foremost statesmen of the empire, but also seriously injured his health to an extent which in the end forced him to abandon politics. He retired from public life altogether in 1913, and died 7th October 1919. See *Life by W. Murdoch* (1923).

**Deal**, a municipal borough and sea-bathing place, in the east of Kent, on a bold open beach, near the south extremity of the Downs, between North and South Foreland, 89 miles by rail from London, and 6 miles SE. of Sandwich. Till 1885 it was part of the parliamentary borough of Sandwich. A fine anchorage extends 7 or 8 miles between Deal and the Goodwin Sands. Deal has mainly arisen to supply the wants of the numerous vessels which are often detained by the winds in the Downs. The chief branches of industry are connected with maritime pursuits, boat-building, sail-making, piloting or hovelling, victualling and naval stores. The prosperity of the place now largely depends on its sea-bathing, on the military dépôt at Walmer (2 miles S. of Deal), and on the shipping in the Downs. The handsome iron promenade pier was erected in 1864. Pop. (1851) 7067; (1921) 12,990. It has been one of the Cinque Ports (q.v.) since the 13th century. Of the three castles built by Henry VIII. in 1539, Deal Castle is the residence of its 'captain'; Sandown Castle (where Colonel Hutchinson died) to the north, has been blown up (1880-95) as dangerous through the encroachment of the sea; and to the south, Walmer Castle (q.v.) is now the residence of the Warden of the Cinque Ports. See H. S. Chapman, *Deal Past and Present* (1891).

Some maintain that it was near Deal that Julius Cæsar landed in 55 B.C.—The Deal boatmen are, like some of the other boatmen on that coast, locally known as 'hovellers.' They are noted for giving assistance to ships in distress, and were formerly much employed in carrying off provisions to outward-bound vessels, and in bringing ashore mail-bags requiring to be forwarded by express.

**Dealfish** (*Trachipterus*), a genus of deep-sea bony fishes, in the Ribbon-fish (q.v.) sub-order of Acanthopteri. As the name suggests, the elongated body is laterally compressed, and with the exception of a small separate anterior portion, the dorsal fin is continuous along the back. The tail fin is peculiar in being turned sharply upwards. The pectoral fins are well developed. The skeleton is very brittle. Some eight species are known, on European coasts and from the west of South America. They rarely come to the surface. One form (*T. arcticus* or *bogmarus*, the vaagmaer of Icelanders and Norwegians) is occasionally found on North British coasts. It is a large fish, 4 to 6 feet in length, and of a silvery colour. The dorsal and caudal fins are red. A smaller species (*T. tænia*) occurs along with others in the Mediterranean.

**Dean**. The word dean, from the Greek *dekanos*, probably means an officer over ten subordinates, the etymon being *deka*, 'ten.' It is first found as a military grade, being mentioned by Vegetius in the 4th century as an old but then disused term (*De Re Milit.* ii. 8). Somewhat later it appears, still in the 4th century, as a title of certain minor officers in the imperial household (St Ambrose, *Epist.* i. 20; St Chrysostom, *Hom.* 13, in Heb. vii.). With the rise and organisation of monachism, the name was given to a monk placed in charge of ten others, for whose discipline or execution of appointed tasks he was responsible (St Augustine, *De Mor. Eccl. Cath.* i. 31); and in the legislation of Justinian the word has yet another sense, being applied to the public officers having superintendence of funerals (*Novell.* 43, 59). In the Visigothic and Anglo-Saxon codes the *decanus* is a judge of first instance or other legal officer having jurisdiction within a tithing, for every hundred consisted of ten districts, called tithings, and in every tithing was a constable or civil dean. The monastic model was adapted to collegiate and other churches having a large staff of clergy, and the dean in such churches presided over ten canons or prebendaries, though this rule of number does not seem to have been strictly required. In conformity with this, the spiritual governors, the bishops, divided each diocese into deaneries or decennaries (Lat. *decem*, 'ten'), corresponding to tithings, each of which was the district of ten parishes or churches, over every one of which a dean was appointed, who in the cities or large towns was called the dean of the city or town, and in the country, *dean of Christianity*, or *rural dean*. In the English Church there are the following dignitaries who bear this name:

(1) In the province of Canterbury it is part of the dignity of the archbishop to have prelates to be his officers, and of these the Bishop of London is his provincial dean; and when a convocation is assembled, the archbishop sends to him his mandate for summoning the bishops of the province. This is the sole example of the kind.

(2) *Honorary Deans*, as the Dean of the Chapel Royal of St James's. See CHAPEL ROYAL.

(3) *Deans of Peculiars*, as of Battle in Sussex, founded by William the Conqueror in memory of his conquest. There are also the Deans of the Arches in London, of Bocking in Essex, and of Croydon in Surrey, who have jurisdiction, but no cure of souls.

(4) *Deans of Chapters*, as at Canterbury, St Paul's, &c., who are governors over the canons in cathedrals and collegiate churches. Their appointment is in the direct patronage of the crown, which may appoint by letters-patent; and the dean so appointed is entitled to be installed. The dean of a chapter must reside eight months in the year, and he may hold one benefice with his deanery. See CATHEDRAL.

(5) *Rural Deans*.—This is a very ancient office of the church, but custom gradually transferred its duties to the archdeacon, as in the visitation of churches, parsonage-houses, &c. Rural deans, however, may act as deputies to the bishop and archdeacon; and since 1850 the office has been revived with great advantage, and in well-ordered dioceses affords a useful channel of communication between the bishop and his clergy, and a means of joint action in matters affecting the church.

In the universities of Oxford and Cambridge the dean is the officer who superintends the discipline of the college and the chapel services. At Christ Church, Oxford, which is a cathedral, the dean is master of the college.

In the Roman Curia the Cardinal-bishop of Ostia is *ex officio* dean of the College of Cardinals; but while the head of foreign collegiate churches is styled dean, the officer bearing that title in cathedral churches is inferior in rank to the provost in some cases, and in others to the vicar-general; and in feudal times the clerks who acted as deputies for the lay-abbots of impropriated foundations were also styled deans.

**Dean**, FOREST OF, a picturesque hilly tract, 34 sq. miles in extent, in the west of Gloucestershire, between the Severn and the Wye, and within the hundred of St Briavels, is an ancient royal forest. It was almost entirely disafforested by Charles I., on a sale to Sir John Wintour, but was re-afforested by act of parliament very shortly after the Restoration. The greater part still remains crown property; and about one-half is appropriated for the growth of timber for the navy. It is divided into six 'walks,' which contain woods of oak, beech, &c. There are coal and iron mines, and quarries of stone suitable for building and making grindstones, troughs, and rollers. Persons born in the hundred, and residing and working a year and a day in the mines, become, on registration, free miners. Their ancient privileges, entitling them exclusively to grants of the crown mines (subject to the right of the crown to put on a fifth man for every four miners, now commuted for a royalty), and, formerly, to timber for the mines, were regulated and enforced by the Mine Law Court, held at the Speech House, within Dean Forest, where the Verderer's Court is still held; but have, with some variations, been defined and confirmed by several acts and commissioners' awards of the present century. Dean Forest is under the control of the Commissioners of Woods and Forests, one of whom, as 'gaveller,' has the supervision of the mines, and a deputy-surveyor, deputy-gaveller, registrar, four verderers (whose office, since the extermination of the deer in 1854 is almost a sinecure), and other officials.

**Dean of Faculty**. See ADVOCATES, UNIVERSITIES.

**Dean of Guild**, in Scottish burghs, was the head of the mercantile body called the Guild-brethren (see GUILD). In former times (Act 1593, chap. 180) he was a judge in mercantile and maritime causes within the burgh, but for a very long period he has been rather a kind of *Adile* (q.v.). His chief duty is now to see that buildings within the burgh are erected according to law, and, in case of their falling into a ruinous condition, to order them to be pulled down. Though in some of the larger

burghs the dean of guild is still (3 and 4 Will. IV. chap. 76, sect. 22) a member of the town-council *ex officio*, his jurisdiction is altogether separate from that of the baillie-court. In Edinburgh the Dean of Guild Court consists of the dean of guild, seven members of the town-council, and seven registered electors of the city, not being councillors, of whom three must be architects, civil engineers, ordained surveyors, or master-builders. They are assisted by the law assessors of the magistrates of the city. No building can be either erected or demolished, or even materially altered, without a warrant from this court. Ventilation and sanitary arrangements are under the control of this court. Opposition to the granting of the warrant may be offered either by a private party or by the corporation acting for the public interest. The enforcement of the Act 1698, chap. 8, as to the height of buildings, the thickness of the walls, &c., lies within the province of the Dean of Guild Court. The judgments of the Dean of Guild Court may be reviewed by the Court of Session.

**Death**. It is one of the fundamental doctrines of physiology, that every part of the organism has its own definite term of vitality, and that there is a continuous succession of the destruction of old cells and the formation of new ones in all tissues, and especially in those in which the most active vital changes are going on, as, for example, in the nervous and muscular tissues. Even the most solid portions of the animal frame, such as the bones and (to a less extent) the teeth are undergoing a perpetual although a slower change of this nature; and throughout the whole body there is a continuous removal of effete or worn-out tissues, and a corresponding deposition of new matter. Every blow we strike, every thought we think, is accompanied by the death and disintegration of a certain amount of muscular or nervous tissue as its necessary condition; and thus every action of our corporeal life, from its beginning to its close, takes place at the expense of the vitality of a certain amount of organised structure. This is termed *molecular death*, and, within its proper limits, is obviously essential to the life and well-being of the organism.

The cessation of the circulation and respiration may be regarded as constituting *somatic death*, or the death of the entire organism, which must obviously be shortly followed by the molecular death of every portion of the body.

We shall now briefly notice the principal modes in which death occurs. Death happens either from the natural decay of the organism, as in old age, or (and much more frequently) from some of those derangements or lesions of the vital organs which occur in the course of the diseases and injuries to which we are liable. These derangements of the vital organs may occasion various modes of dying. Dr Watson said that life rests on a tripod, whose three vital supports are the *heart*, the *brain*, and the *lungs*; and Bichat, that 'the mode of dying may begin at the head, the heart, or the lungs.' The functions of these organs are, however, so mutually dependent upon each other, that impairment in the functions of one of them may lead to death, though the immediate cause of death is the failure of another.

*Death from failure of heart* may be either sudden or gradual. Sudden failure (death by *syncope* or fainting) may occur from disease or weakness of the heart itself, or from shock conveyed to it through the nerves. Gradual failure takes place when the whole system is enfeebled—e.g. by the action of certain poisons, and by many wasting diseases (death by *asthenia*, Gr., 'want of power'). When death occurs from loss of blood (*anæmia*), the failure of the heart may be either sudden or

gradual, according to the extent of the loss; but in this case the heart ceases to contract, not from inability to do so, but because the blood, its natural stimulus, is insufficient in amount to excite contraction.

*Death from failure of respiration* (Asphyxia, q.v.) occurs when access of the air to the lungs is impeded, or when the actions of the muscles of respiration cease. We have examples of it in drowning, smothering, choking, strangulation, &c. Forcible pressure upon the chest, such as sometimes happens in great crowds, or as occurs to workmen partially buried by the fall of earth, &c., will cause death in a few minutes, if movement of the lungs is prevented by the pressure. Tetanus and the poison of strychnine prove fatal in this way.

*Death by coma*, or beginning at the brain, is caused by obstruction to the circulation through that organ by pressure (as, for example, when there is effused blood within the cranium, or when a portion of bone is depressed in a fractured skull); by clots of blood within the vessels; by various narcotic poisons, such as opium, alcohol in excessive quantity, carbonic acid, &c.

Death may also be due to the profound effect produced upon the system by a number of injuries not involving any essential organ (multiplicity of injuries); or by the shock of a severe damage to an important organ, such as shattering of the kidney and adrenal body by a gunshot wound. Death may then take place within a few hours.

The signs of approaching death require a brief notice. The mind may be affected in various ways; there may be dullness of the senses, vacancy of the intellect, and extinction of the sentiments, as in natural death from old age; or there may be a peculiar delirium, closely resembling dreaming, which usually is of a pleasing and cheerful character.

Dementia or imbecility sometimes comes on shortly before death, and manifests itself by an incapacity of concentrating the ideas upon any one subject, and by an almost total failure of memory. The mental weakness is often exhibited by the pleasure which is derived from puerile amusements. Shakespeare notices 'playing with flowers' as a token of approaching dissolution. In the form of delirium, ocular spectra seem frequently to be present, the patient apparently trying to catch some imaginary object.

There is generally well-marked relaxation and incapacity of the muscular system, and the voice is usually weak and low as death approaches, often dwindling to a mere whisper. The mode in which the action of the heart declines is various; in most diseases of long standing, the cessation of the heart's action is gradual, the rate of the pulsations being much increased, but their energy being very much impaired. In some acute affections, the failure is shown by the irregularity of the pulse, while the force is little altered. In other cases (especially in cerebral diseases) the heart, before finally ceasing to beat, contracts violently, and suddenly stops.

The respiration is sometimes hurried and panting till just before death, while in other cases it is slow, laborious, and stertorous. The accumulation of mucus, &c. in the air-passages increases the difficulty of breathing; the sound known as the 'death-rattle' being produced by the passage of the air from the lungs through the fluid collected in the trachea and upper respiratory passages. There is also a loss of animal heat, beginning at the extremities.

The signs of actual death may be arranged under three heads: (1) Signs of the extinction of the vital functions; (2) Changes in the tissues; (3) Changes in the external appearance of the body.

(1) The arrest of the circulation and respiration

would at first sight appear to afford decisive evidence of death; but these functions, as in the case of hibernating animals, may be reduced to so low a condition that it is by no means easy to decide whether or not they are completely annihilated. In cases of apparent drowning, and in newly-born infants, these functions are frequently suspended and again restored; and cases like that of Colonel Townsend (see any standard work on medical jurisprudence) occasionally occur, in which the patient has the power of voluntarily suspending these functions for a considerable period. The gradual loss of animal heat is an important sign. But it is sometimes delayed; and in exceptional cases a rise of temperature may even take place after death. Loss of contractility of the muscles when a galvanic current is applied to them is a sign of death; but the period at which it takes place is very variable. Distinctive minor signs are the absence of blistering and redness if the skin be burned (Christison's sign); the failure of a ligature tied round the finger to produce, after its removal, the usual change of a white ring, which after some seconds becomes redder than the surrounding skin in a living person; and the absence of bleeding if a vessel be opened.

(2) Among the changes in the tissues, the *rigor mortis*, or rigidity of the muscles, which ensues at a varying period after death, is the most important. It may appear within half-an-hour after death, or may be delayed twenty or thirty hours, according to the nature of the disease; and it usually lasts about two days. It commences in the neck and trunk, then appears in the upper, and lastly in the lower, extremities, and disappears in the same order.

(3) Various changes in the external appearance of the body take place. Of these the most important is the altered colour of the surface. Livid spots (resembling bruises) appear on the dependent parts; and a green tint on the skin of the abdomen, followed by a separation of the epidermis, is a sure sign that life is extinct and putrefaction has begun.

The discrimination of true from apparent death is obviously not a matter of mere physiological interest. The case of Vesalius, the eminent anatomist, who opened an apparently dead body in which the exposed heart was seen to be still beating, is well known; but the belief that the Abbé Prévost (q.v.), having been struck down by apoplexy, was regarded as dead, but recovered his consciousness under the scalpel, has been shown to be unfounded. A French author, Bruhier, in a work *On the Danger of Premature Interment* (1742-45), collected fifty-four cases of persons buried alive, four of persons dissected while still living, fifty-three of persons who recovered without assistance after they were laid in their coffins, and seventy-two falsely considered dead. But when reasonable care is taken such mistakes are hardly possible. See BURIAL, CATALEPSY.

Death, in a legal point of view, is either natural or civil: the former being the cessation both of physical life and of the legal rights which attach to it; the latter, the cessation of the legal rights whilst the physical life remains. A man was said to be civilly dead in England when he had been attainted of treason or felony, or had abjured the realm, or was banished, or became professed in religion by going into a monastery. In these events his property devolved as if he were naturally dead. The doctrine of civil death is now abolished except as to cases of outlawry, in which it seems still to be applicable.

According to the Scottish Law of Death-bed, an heir in heritage was entitled to reduce all voluntary deeds granted by his ancestor to his prejudice, if they were granted by this ancestor on his death-bed. It was necessary that at the time the deed

was granted the ancestor should be suffering from the disease of which he died, and not survive for more than sixty days; nor did the law (repealed 1871) apply if, after granting the deed, he was able to go unsupported to kirk or market.

**Death Duties**, a comprehensive term for the specific duties, levied under various acts of parliament, on the estates of deceased persons. They include legacy, succession, and estate duties, and in general terms may be explained as follows: Legacy duty is payable in respect of any gift by will which shall be satisfied out of the movable property of the deceased, distributed shares of movable property devolving under intestacy, and on shares of residue when payable out of a mixed fund arising from heritable estate directed to be sold, and movable estate. It varies in rate: husband or wife or lineal issue and lineal ancestors pay £1 per cent. (but this is not charged when the total estate does not exceed £15,000, or when the value of the benefit to the individual beneficiary does not exceed £1000, or, if the beneficiary is the widow or a child under twenty-one, does not exceed £2000); lawful brothers and sisters or their descendants pay £5 per cent., and persons of a more remote degree of consanguinity, as well as strangers in blood (including illegitimate children of the deceased), pay £10 per cent. No legacy duty is chargeable when the whole of the movable property does not amount to £100, or when the net value of the heritable and movable property on which estate duty is payable does not exceed £1000. Succession duty (Act of 1853) is payable in respect of succession to heritable or movable property passing upon the death of any person. The three essential characteristics of a succession are a disposition or devolution of property, a gratuitous acquisition, and a death on which the property is transmitted. The rates of succession duty are similar to the rates of legacy duty.

Estate duty, which was introduced by the Finance Act, 1894, is payable upon the principal value of all property, heritable or movable, settled or not settled, which passes upon the death of a person who dies after 1st August 1894, and includes all the property which the deceased was competent to dispose of at his death, whether he actually disposed of it or not; gifts made within three years of his death without reservation; gifts made at any time with a reservation in favour of the deceased, &c. Among the exceptions (which are mainly technical) are the property of common seamen or soldiers, or airmen, who die in the service of the crown, Indian government pensions passing to widows and children, and gifts to the nation. The rates are: above £100 and under £500, £1 per cent.; between £500 and £1000, £2 per cent.; between £1000 and £5000, £3 per cent.; between £5000 and £10,000, £4 per cent.; between £10,000 and £15,000, £5 per cent.; and so on in a graduated scale, rising to £40 per cent. for an estate of over £2,000,000 (Finance Act, 1919, sect. 29). Estate duty, which has practically superseded probate duty and account duty, is chargeable on all property passing on death without regard to the relationship of the beneficiaries to the deceased owner. In determining the rate of estate duty the principle of 'aggregation' is, subject to certain exceptions, applied. This means that where several distinct estates pass on a person's death—for instance, his free estate under his will and settled property under his marriage settlement—it is necessary, in order to determine the rate of duty in respect of any particular estate, to aggregate it with the other estates passing. In the case of

real estate the accountable parties have an option of payment by instalments, viz. by eight yearly instalments, or sixteen half-yearly instalments. Should the owner die before all instalments are paid, the unpaid instalments are still payable, and are a charge on the property in the hands of the successor. Certain deductions are allowed in respect of land or a business where there has been a second death within five years.

Settlement estate duty, which was an additional estate duty charged on settled property, was imposed by the Finance Act, 1894, but was abolished by the Finance Act, 1914, in the case of deaths occurring after 11th May 1914. Under the statutes in force since the abolition of settlement estate duty, estate duty is payable on each passing of settled property, subject to an important exception in favour of married persons.

**Death's-head Moth** (*Acherontia atropos*), a species of Hawk-moth (q.v.), in the family

Death's-head Moth (*Acherontia atropos*) and Caterpillar.

Spingidae, not uncommon in some parts of England and of the continent of Europe. It is widely distributed over the world, being found in Africa, Mauritius, and the East Indies. It is one of the largest of the European Lepidoptera, and measures almost six inches from tip to tip of the extended wings. The general colour is dark, the woolly body yellow, with black markings, the thorax with markings which have some resemblance to a skull, the upper wings mottled with brown, black, and yellow, the hind wings dark yellow with two black bands. The large caterpillar is greenish-yellow, the back speckled with black, with transverse lines partly blue and partly white. The tail end bears an S-shaped horn. In countries where the potato is cultivated it is often to be found feeding on the leaves of that plant. In the pupa stage it is brown, and lies in a hole in the ground. The insect is nocturnal in habit, and is interesting as an audacious plunderer of bee-hives. How it daunts the bees is a mystery. Even more remarkable is the much discussed shrill piping note.

**Death Valley**, a peculiarly desolate depression, 135 miles long by 10 to 20 wide, in the S.E. part of California. Some of it is salt desert, 480 feet below sea-level; vegetation is absent, or very scanty and arid. The summer temperature reaches 122° in the shade.

**Death-watch**, a ticking or rapping noise produced by various insects in houses. Being

oftenest heard in the quiet of sickness and anxiety, it has been superstitiously regarded as a signal of approaching death. In Britain it is generally the love-signal of the small boring beetle (*Anobium*, see BORERS), of a brownish colour, and about  $\frac{1}{2}$  inch in length. Various species frequent wood, furniture, &c. *A. pertinax*, *A. tessellatum*, and *A. striatum* are all common death-watches. Some other insects besides *Anobium* make tapping noises, notably the Giant Cockroach (q.v.) or drummei.

**De Bary, HEINRICH ANTON** (1831-88), a botanist born at Frankfort-on-Main, studied medicine at Heidelberg, Marburg, and Berlin, and from 1855 was professor of Botany at Freiburg, from 1867 at Halle. In 1872 he was appointed the first rector of the newly reorganised university of Strassburg. He vastly extended our knowledge of the fungi and other plants by such works as *Comparative Anatomy of Phanerogams and Ferns*, *Morphology of Plants*, and *Lectures on Bacteria* (1888).

**Debateable Land.** See BORDERS.

**Debenture** is a deed or instrument issued by a company or public body acknowledging a loan of money. As a rule it charges the property of the company with the payment of interest, and the repayment of the principal at some fixed period, usually three, five, or seven years. Debentures vary in their terms, style, and legal incidents according to the statutes under which power is given to issue them. One common and important form is the railway debenture, which is a mortgage issued under the Companies Clauses Acts, &c., and containing an assignment of the whole undertaking and receipts of the company. Debentures of a company registered under the Companies Act, 1908, generally create a charge on the property of the company, but are sometimes merely bonds, or in the form of promissory notes. In many cases the issue of debentures has been superseded by the issue of debenture stock, which, with the interest thereon, is usually a charge on the undertaking of the company prior to all shares or stock of the company. Each debenture is a separate bond, and cannot be divided, whereas the holder of debenture stock has a certificate (which must be registered) entitling him to a definite sum out of a consolidated capital loan, generally secured by a trust or covering deed, and fractions of his holding may be freely transferred.

**Debit and Credit.** See BOOK-KEEPING.

**Deborah** (Hebrew, 'bee'), the 'Mother in Israel,' a Hebrew prophetess, who stirred up the tribes of northern Israel under Barak to destroy a great army of the Canaanites in the plain of Esdraelon. Sisera, the Canaanite leader, fled, and was murdered in his sleep by Jael. For the song of Deborah (Judges, v.), see Ewald, *Die poetische Bucher des alten Testaments*; Cooke, *History and Song of Deborah* (1892); and an eloquent passage on this 'Hebrew Boadicea' in Coleridge's *Confessions of an Inquiring Spirit*.

**De'breczen**, in the midst of a wide plain of Hungary, 130 miles E. of Budapest, is a large straggling place, or rather a collection of villages. Its college is the chief Reformed college in Hungary, and is now a faculty in a university founded in 1912; there are also a Catholic academy, a commercial college, and an agricultural college. There is much trade in cattle, swine, and grain, with manufactures of flour, soap, saltpetre, sausages, hams, and tobacco-pipes. Pop. 93,000, almost all Protestants. The 'Rome of the Calvinists,' De'breczen was long the headquarters of the Reformed faith, and its inhabitants suffered much for their religion. In 1849 it was for some months the seat of the national diet.

**De Brosse.** See BROSSES.

**De Bry, THEODOR** (1528-98), goldsmith and copperplate engraver, born at Liège, established a printing-house at Frankfort-on-Main about 1570, whence issued a famous collection of Voyages to the East and West Indies, published in Latin and German (1590-1634).

**Debs, EUGENE VICTOR**, American Socialist leader and journalist, born at Terre Haute, Ind., 5th November 1855, became secretary and treasurer of the Brotherhood of Locomotive Firemen (1880), and sat in the Indiana legislature. In 1897 he entered the Socialist movement. From 1900 onwards (except in 1916) he was Socialist candidate for the presidency. His pacificism led to a sentence (1918) of ten years in a penitentiary under the Espionage Act. President Wilson refused to allow his release, and he fought the 1919 campaign from prison, securing nearly a million votes. He was released in 1921.

**Debt** is an obligation to pay a definite sum of money. The person who is under the obligation to pay is the debtor; the person who has the right to receive payment is the creditor. Where the sum claimed as due is not definitely ascertained, it is, properly speaking, not a debt, but a claim for damages. A debt which exists (*debitum in presenti*), but which is not exigible till a day or event certain to occur—e.g. the death of a particular person—is termed a 'future' debt. Such a debt is to be distinguished from a 'contingent' debt, which has no existence until the fulfilment of a condition, or the occurrence of an uncertain event. A creditor who, in addition to his right of action and execution against the debtor in virtue of the latter's personal obligation, holds some other right or means for the recovery of the debt is said to hold a right in security for the debt. Such a right may consist in a right over property, real or personal, conveyed to, or acquired by, the creditor (see MORTGAGE, PAWNBROKING, LIEN), or in a right against some third person who has undertaken to see the debt paid (see GUARANTY, CAUTION, SURETY).

In England a debt arising from a contract not under seal is a simple contract debt. A debt created by a deed—i.e. by an instrument under seal—is a specialty debt. An action on a simple contract debt must, under the Statutes of Limitation, be brought within six years; an action on a specialty debt, within twenty years. The time in both cases runs from the date when the cause of action arises; but if a subsequent acknowledgment in writing has been made by the party liable, or his duly authorised agent, or if he has paid the debt in part, or paid interest, the time will run from the date of such subsequent act. Debts of record are debts evidenced by the records of a court. In this category are included recognisances—i.e. obligations entered into before a court or magistrate—and judgment debts. A judgment debt comes into existence whenever in any action in a court of record a sum is adjudged to be due by one person to another. When a judgment has been obtained in respect of a debt, whether a simple contract debt or a specialty debt, or, as it may be, in respect of a claim of damages, the original debt or claim is thenceforth extinguished, being merged in the judgment debt.

On the death of a debtor the claims of practically all creditors now lie against the personal representatives of the deceased, in whom his real, as well as his personal, assets vest (Land Transfer Act, 1897). In administering the estate of a deceased person, the order of preference to be observed by the executor is as follows: (1) funeral expenses, the costs of proving the will and the

like; (2) debts due to the crown; (3) debts rendered preferable by statute—e.g. income-tax, poor-rates; (4) debts of record, including judgment debts and recognisances by the deceased; (5) all other debts of which the executor has notice, whether they are simple contract or specialty debts. It is a prerogative of the crown to take precedence of all other creditors, and, in England, to recover its debts by a summary process called an *Extent* (q.v.). By 33 Henry VIII., chap. 39, this preference is given over all creditors who have not obtained judgment for their debts before the commencement of the crown's process; and the Act 6 Anne, chap. 26, extended the law of England in this respect to Scotland. The rule in Scotland was limited to movable or personal property. In Scotland the Exchequer Act, 1856, introduced new forms of procedure for the recovery of crown debts, which have virtually superseded writs of extent. In a sequestration the crown has a statutory preference for one year's arrears of income and property tax, and other imperial taxes. A similar preference is given for poor and school rates. By statute special methods are provided for the recovery of estate and other death duties. See EXCHEQUER. The advantages which creditors in specialty debts previously enjoyed over creditors in simple contract debts have been abolished by statute, and now, on the death of a debtor, these two classes of debts are payable *pari passu*. Provision must also be made by the executor for payment of future or contingent debts of the deceased. Certain debts—e.g. debts secured on particular property by mortgage—are primarily charged on that property; but none the less the executor or administrator is bound to see that these debts are paid.

On the bankruptcy of a debtor certain kinds of debts are entitled to priority in the distribution of the debtor's assets among creditors. Such preferential debts include parochial and other local rates, income-tax, and other assessed taxes due by the bankrupt, to the extent of one year's assessment; the wages of servants or clerks, not exceeding £50 each, due in respect of the period of four months before the date of the receiving order; wages of labourers or workmen not exceeding £25, due in respect of the period of two months before that date; claims for compensation under the Workmen's Compensation Act, 1906; and contributions due from the employer under the National Insurance Acts, 1911 to 1920, and under the Unemployment Insurance Act, 1920. There are, too, certain debts—e.g. a debt for money lent by a wife to her husband, or by a husband to his wife, to be employed in trade—which are postponed to other debts, so that they are paid only after all other debts for value have been paid in full. Apart from these exceptions, the estate of the bankrupt is distributed rateably among his creditors, no distinction being made between simple contract debts, specialty debts, and judgment debts or other debts of record. A secured creditor—i.e. a creditor who holds a mortgage or lien on any property of the debtor as security for a debt due to him from the debtor—cannot prove in the bankruptcy for the whole of his debt, and at the same time retain his security. He may realise his security, or put a value on it, and prove and receive a dividend *pari passu* with the other creditors in respect of the balance of the debt remaining unpaid after deducting the proceeds or value of the security. Or he may choose to hand over his security to the trustee and prove in the bankruptcy for his whole debt. (See BANKRUPTCY.)

The debtor is bound, in the ordinary case, to find the creditor and offer payment of the debt. When the debtor owes the creditor several different debts, some of which may be secured and others

not, the debtor, on making payment of any sum which is not enough to extinguish all the debts, is entitled to appropriate the payment to any particular debt—e.g. a debt which is secured by mortgage or otherwise; and, if this is clearly done by the debtor at the time of payment, the creditor cannot apply the sum in satisfaction of any other debt—e.g. an unsecured debt. On the other hand, where a sum is paid without any specific appropriation by the debtor, the creditor is entitled to apply it to any debt he pleases, even to a debt on which action is barred by the Statutes of Limitation. (See APPROPRIATION.) A written receipt for the amount of a debt is *prima facie* evidence of payment. Any form of words sufficient to show that the debtor is discharged constitutes a receipt. Where the receipt is for £2 or upwards, it (subject to certain exceptions) must bear a twopenny stamp, which must be cancelled by the person by whom the receipt is given before he delivers it. The creditor is liable to a fine of £10 if, where a receipt is liable to duty, he gives a receipt not duly stamped or refuses to give a receipt duly stamped. When a debt is incurred it may be agreed that interest at a certain rate shall be paid from a particular date, and such an agreement may be inferred from a course of dealing between the parties. Apart from such an agreement, express or implied, interest is not, as a general rule, recoverable on a simple contract debt. Interest, however, is payable on a bill of exchange, a promissory note, and a bond for money; and a judgment carries interest both on debt and costs. Also, by statute 3 and 4 Will. IV. chap. 42, a judge or jury may award interest or damages 'upon all debts or sums certain payable at a certain time or otherwise, . . . if such debts or sums be payable by virtue of some written instrument at a certain time, or, if payable otherwise, then from the time when demand of payment shall have been made in writing.' As to assignment of debt, see ASSIGNATION.

When judgment has been obtained in respect of a debt, it will be enforced, if need be, by 'execution.' The process of execution is, generally speaking, effected by a writ, directed to the sheriff or other proper person, authorising and ordering a sufficient part of the debtor's property to be seized and sold, or otherwise made available for payment of the debt (see EXECUTION; ATTACHMENT; GARNISHEE). Formerly execution might be made against the debtor's person, and he could be kept in prison indefinitely in default of payment. But, since 1869, imprisonment for debt has been abolished in England, except in certain special circumstances (see *Imprisonment of Debtors*, infra).

In the *United States* the classification of debts and the rules as to payment, interest, periods of limitation, priority, and execution are substantially identical with the classification and rules obtaining in English law.

In *Scotland* the classification of debts adopted in English law has no place. In Scots law writing is necessary, in certain cases, to constitute an obligation, and, in other cases, to prove the obligation. Thus, where a loan exceeds £8, 6s. 8d., it can be proved, in an action for repayment, only by the writ or oath of the borrower. Again, a gratuitous obligation to pay a sum of money is binding; but such a debt can be proved only by the writ or oath of the debtor. But debts arising out of any ordinary consensual contracts, such as sale or hire (unless the contract relates to heritage), or any contract of partnership, affieghtment, or deposit, are provable by oral evidence. An IOU addressed to a person and signed by the grantor is an acknowledgment of debt, and imports an obligation to pay the amount. Under a series of old

Scots acts, a debt is extinguished after the expiry of twenty years by what is called the negative prescription, unless, during the currency of that period, the creditor has taken steps by citation, action, or diligence to enforce his claim, or the debtor has acknowledged in writing the existence of the debt, or has paid interest or part of the principal sum. There are also certain shorter prescriptions, in virtue of which the lapse of a certain time, while it does not extinguish the debt, alters the *onus* and method of proof—e.g. the triennial prescription, applicable to debts in respect of the rent of a house, board and lodging, wages or remuneration for professional work, the accounts of shopkeepers and persons engaged in trade, and other like debts, if not founded on written obligations; the quinquennial prescription, applicable to debts in respect of the rent under a lease of house or land after the tenant has left, and debts arising on bargains concerning movables provable by witnesses; the sexennial prescription, applicable to bills of exchange and promissory notes; and the vicennial prescription, applicable to debts founded on holograph writings. In Scotland, as in England, certain debts, including deathbed and funeral expenses, the rent of the debtor's house, and the wages of his domestic and farm servants for the current year or term, and certain taxes, are privileged, so that, on the death or bankruptcy of the debtor, they fall to be paid in priority to other debts. In Scots law, while execution or diligence cannot, as a general rule, be used on a debt which is future or contingent, yet such a debt may be secured by arrestment or inhibition where the debtor is *vergens ad inopiam*, or upon the dependence of an action.

**RECOVERY OF DEBTS.**—In *England*, the jurisdiction of the county court extends to all personal actions when the amount of the debt or damages sought to be recovered does not exceed £100. In many such cases it is also competent to bring an action in the High Court; but, under various statutes, a plaintiff who sues in the superior court, when he might more properly have brought his action in an inferior court, is deprived of costs, or is entitled only to county court costs. Thus, if the plaintiff, in an action founded on contract, brings the action in the High Court and recovers less than £20, he will not be entitled to any costs whatever; and if he recovers £20 or more, but less than £100, he will not be entitled to recover any more costs than he would have been entitled to if the action had been brought in the county court; unless, in either of the cases mentioned, the judge of the High Court certifies that there was sufficient reason for bringing the action in the High Court instead of the county court. There are similar provisions with reference to other inferior civil courts in which debts of limited amount can be recovered. (As to these courts, see *infra*.) In an action in the county court, the same legal or equitable grounds of defence are available as if the action were tried in the High Court, and the defendant may set up, by way of counter-claim against the plaintiff, any right or claim which he may have against him. England and Wales are divided into 566 county court districts, in each of which a court is held at least once in every month of the year, except September; while in many districts the sittings of the court are more numerous than once a month. The vast majority of actions for the recovery of debts are brought in these courts. The procedure in county court actions is regulated by the County Courts Acts, 1888-1919, and by rules and orders made from time to time under these acts. The action must, as a rule, be brought in the court of the district in which the defendant resides or carries on business.

An ordinary action is commenced by the entry of a 'plaint' in a book kept by the registrar for the purpose—there being a registrar appointed by the judge for each court. If the claim for debt exceeds 40s., the plaintiff, at the time of entering the plaint, must also file particulars of his claim. The registrar thereupon issues a summons, under the seal of the court, which contains the names of the parties, a short statement of the cause of action, and the amount of the debt claimed, and also names a day, called 'the return day,' on which the defendant must appear for the trial of the action. The summons must be served by the bailiff of the court at least ten days before the return day. On the day named in the summons the plaintiff must appear to support his claim; and if the defendant does not appear, judgment goes by default. Where the claim is for a debt or liquidated demand, the plaintiff may, instead of the ordinary summons, issue a 'default summons.' For this purpose he must file an affidavit verifying the debt. If the debt claimed exceeds £5, or is for the price of goods sold or let to the defendant in the way of his trade, leave is not required; in other cases, leave must be obtained. A default summons must be served on the defendant personally; and unless the defendant, within eight days, gives a written notice of defence, the plaintiff may, upon proof of service, have judgment for his debt and costs without further proof. In the case of an ordinary summons, it is not, as a rule, necessary for the defendant to give any notice either to the court or to the plaintiff of his intention to defend the action or of his grounds of defence. Where, however, the defendant intends to rely on any special or statutory defence—e.g. that he was a minor at the time the debt was incurred, or that he has a counter-claim against the plaintiff, or that he has been discharged in bankruptcy, or that the action is barred under the Statute of Limitations—he must, five days before the trial, give a written notice of it to the registrar, who will communicate it to the plaintiff. County court actions are usually tried before the judge without a jury; but where the claim exceeds £5 either party may, on giving at least ten days' notice, obtain a jury, consisting of eight persons. Even in a case where the amount of the claim is less than £5, either of the parties, by leave of the judge, may obtain a jury. The verdict of the jury must be unanimous. At the hearing oral evidence is, if necessary, given by witnesses on oath or affirmation. The judge, if there is no jury, decides all questions both of fact and law. At the end of the case, judgment is given and entered in the minutes of the court. If the plaintiff is found entitled to payment of any sum, the judge may direct the sum to be paid at once, or he may direct payment by instalments. In the latter case, the creditor cannot levy Execution (q.v.) till after default has been made in payment of an instalment; but on such default execution can issue for the whole sum due. The costs of the action, which are according to a fixed scale, have, as a rule, to be paid by the unsuccessful party, though the judge in his discretion may order otherwise. In every case tried in the county court, whether with or without a jury, the judge, on application, has the power to order a new trial. A new trial will only be ordered on cause shown, and on such terms as the judge shall think reasonable. The judge, if he thinks fit to grant a new trial, may order that it shall take place before a jury, although the action was not originally so tried. No appeal lies from the finding of the judge or jury on a question of fact; but if either party to the action is dissatisfied with the decision or direction of the judge on any point of law or

equity, or on the admission or rejection of any evidence, he has a remedy by way of appeal to a Divisional Court of the High Court of Justice. Such an appeal, however, can be taken to the High Court only when the point of law has been raised at the trial before the county court judge. Moreover, in some cases an appeal will not lie without the leave of the county court judge. In particular, where the debt sued for is less than £20, neither party can appeal without such leave. The appellant, within twenty-one days from the date of the judgment, must give notice of appeal to the other party, and enter the appeal in the Crown Office of the High Court of Justice.

In addition to the county courts there are, in England, certain other courts which, in particular cases, have jurisdiction in claims for debts of limited amount. The most important of these courts are the Mayor's Court of the City of London, the Liverpool Court of Passage, the Hundred Court of Salford, and the Bristol Tolzey Court.

In *Scotland*, debts not exceeding £20 are properly recovered in the Sheriff Small Debt Court. The procedure is regulated by the Sheriff Court Acts, 1907 and 1913, and the Small Debt Acts, 1837 to 1889. The summons, which is in a statutory form, specifies the date on which the case is to come before the court, and contains warrant to cite the defender and witnesses. It is signed by the sheriff-clerk. The particulars of the claim must be stated in the summons, or in a separate paper or account, to which reference is made in the summons. The defender is cited by serving on him a copy of the summons and of the account sued on, if any. This must be done at least six days before the date of appearance specified in the summons, and may be done either by a sheriff-officer delivering a copy to the defender personally, or at his dwelling-place, or by a sheriff-officer or law-agent sending a copy to the defender in a registered letter. Either of the parties to the action may appear, on the calling of the case in court, by himself, or by one of his family, or by a law-agent, or, if allowed by the sheriff, by some other person. Where the defender intends to found on a counter-claim, he must serve a copy of it on the pursuer at least one day before the day of appearance. If both parties appear, they are heard by the sheriff, and, if necessary, oral evidence is led. No record of the pleadings or the evidence is kept, but the judgment is recorded in a register kept by the sheriff-clerk and signed by the sheriff. If a sum is found due, it is in the discretion of the sheriff to allow it to be paid by instalments. If there is no appearance for the defender, the pursuer obtains decree in absence, with expenses. The fees of law-agents in a small-debt case, if allowed by the sheriff, are regulated by a special scale prescribed by the Codifying Act of Sederunt, 1913. The same act also provides that where the amount claimed in any Sheriff Court action does not exceed the value which may be competently sued for in the Small Debt Court, small debt expenses only shall be allowed, unless the sheriff shall otherwise appoint. A judgment pronounced in the Small Debt Court cannot be reviewed either on law or on fact; but it is competent to appeal to the High Court of Justiciary against the decree on certain special grounds, viz. corruption, or malice, or oppression, on the part of the sheriff, wilful neglect of statutory procedure, and incompetency, including defect of jurisdiction. In addition to the Sheriff Court, the justices of the peace and the magistrates of burghs possess a small-debt jurisdiction, in cases of debts not exceeding £5.

The Debts Recovery Court, constituted by statute in 1867, for the recovery of debts between £12 and £50, has been abolished by the Sheriff Courts Act

of 1907. The Act of 1907, as amended by the Act of 1913, has, however, provided a special procedure for 'summary causes,' which are defined as meaning actions for payment of money not exceeding £50 in amount, exclusive of interest and expenses. The procedure in a summary cause is, in several respects, more simple and rapid than in an ordinary Sheriff Court action. Where evidence is led, it is not recorded unless the sheriff, on the motion of either party, orders it to be recorded.

An action for payment of money exceeding £50 in amount, exclusive of interest and expenses, may be brought either in the Sheriff Court or in the Court of Session, and proceeds as an ordinary action in either of these courts.

**IMPRISONMENT OF DEBTORS.**—Formerly, both in England and in Scotland, if the defendant in a civil action for debt had no property out of which the amount for which judgment had been given could be realised, the person of the debtor could generally be seized in execution. The debtor, in other words, could be imprisoned until payment of the debt.

In *England*, imprisonment for debt was abolished by the Debtors Act, 1869, except in certain cases. Of these exceptional cases, the most important in practice is where the failure to pay a judgment debt is wilful. Under the Debtors Act, the judge of a county court has power to commit to prison, for a period not exceeding six weeks, a judgment debtor who fails or refuses to pay the debt, on proof that the debtor has means to satisfy the order for payment made by the court. The burden of proving that the debtor has the means to pay lies on the creditor. The imprisonment does not extinguish the debt; but the debtor may obtain his release at any time by making payment of the debt. To obtain an order committing the debtor to prison, a judgment summons must be issued and be served personally on the debtor. Such committal orders are very frequent in practice in England, the number of debtors so imprisoned exceeding ten thousand annually. In the Debtors Act, 1869, modified by the Bankruptcy Acts, 1883 to 1914, provision is also made for the punishment of fraudulent debtors. The consolidating Bankruptcy Act, 1914—the statute on which the existing bankruptcy system now mainly rests—enumerates various acts which, if done by a person adjudged bankrupt or in respect of whose estate a receiving order has been made, are misdemeanours punishable by imprisonment for two years. Under sect. 159 of the statute of 1914 it is a felony, punishable with two years' imprisonment, for any bankrupt, after the presentation of a bankruptcy petition, or within six months before that date, to abscond, or attempt or prepare to abscond, from England, taking with him property to the value of £20, unless he proves that he had no intent to defraud. It is also a criminal offence for any person, whether he be a bankrupt or not, with intent to defraud his creditors, to conceal or remove any part of his property since, or within two months before, the date of any unsatisfied judgment, or order for payment of money, obtained against him.

In *Scotland* the severity of the law of imprisonment for debt was, at an early period, mitigated by the introduction of the process of *Cessio bonorum* (q.v.). By the Debtors Act, 1880, and the Civil Imprisonment Act, 1882, imprisonment for debt has been abolished except in case of non-payment of taxes, fines, penalties due to the crown, and rates or assessments lawfully imposed; wilful refusal to pay sums decerned for aliment; and failure to implement a decree *ad factum prestandum*. The maximum period of imprisonment for non-payment of taxes, fines, and crown penalties is a year; and for non-payment of rates and assess-

ments for any year, six weeks. A person who wilfully refuses to pay an alimentary debt may be committed to prison for six weeks, and this punishment may be repeated at intervals of not less than six months. In those cases in which imprisonment for debt is still competent in Scotland, a creditor is entitled to obtain a warrant to imprison a debtor if there is ground to believe that he is *in meditatione fugæ*. Such *meditatio fugæ* warrants were formerly common; but, since the old matter-of-course imprisonment for debt has been abolished, such a warrant can be granted only in the case of those debts in which imprisonment may follow on the decree.

In the *United States* imprisonment of debtors was, as in England, originally recognised at common law as a means of enforcing payment of debts. But at the present time, by provisions in the constitutions of the several states or by laws passed for the relief of 'poor debtors,' imprisonment for debt has been abolished in all the states. The purport and effect of the laws passed for the relief of poor debtors is to relieve the debtor's body from restraint upon a surrender of his goods and estate. While legislation has relieved the honest debtor from imprisonment, it has subjected fraudulent debtors to punishment. Thus, by statutes in force in many states, the secreting of goods with intent to defraud creditors is an indictable offence. To constitute this offence there must be (1) an actual fraudulent secreting, assigning, or conveying of goods, or a fraudulent reception of goods; and (2) an intent to prevent such property from being made liable for the payment of debts, or, in case of reception, a guilty knowledge of such intent.

**ANCIENT LAWS OF DEBTOR AND CREDITOR.**—The Mosaic Law as to the relation of creditor and debtor combined a degree of lenity with a degree of severity which are equally alien to modern views. If an Israelite became poor, it was a duty to lend to him, and no interest was to be exacted either in money or in produce. If he was a foreigner the case was different, and the taking of interest was legal (Exod. xxii. 25; Deut. xxiii. 19, 20; Lev. xxv. 35–38). When the Sabbatical year arrived—i.e. at the end of every seven years—there was a general remission of debts as between Israelite and Israelite; and the near approach of the year of remission was not to be recognised as an apology for declining to lend to an indigent brother (Deut. xv. 1–11). Pledges, it is true, might be taken, but even here the same humane principles prevailed. The upper millstone was sacred, for to take it would be to deprive the debtor of the means of subsistence. If raiment was the pledge, it must be returned before nightfall, when it might be required for a covering (Exod. xxii. 26, 27); and the widow's garment could not be taken in pledge. In strange contrast to this is the provision (Lev. xxv. 39) that a poor Israelite may be sold to one possessed of substance, even when modified by the special provision that he shall serve as a hired servant, not as a bond-servant, and shall be set at liberty when the year of jubilee arrives. Michaelis says that the judicial procedure for debt was quite summary, the most important causes being decided probably in a single quarter of an hour; and he remarks that Moses nowhere thinks it necessary to mention how a debt was to be proved before a judge. There was, however, an extensive system of appeal; from the judge over 10, the case was carried to the judges over 50, 100, and 1000, and finally to Moses himself. As every Israelite was entitled to claim the land of his fathers at the jubilee year, and thus to place matters on the footing on which they were after the settlement in Palestine, debts and burdens on land were limited to claims to the fruits of forty-two harvests; but houses, with the exception of

those of the Levites, might be sold in perpetuity (Lev. xxv. 29, 30, 32, 33). Children were often given in pledge (Job, xxiv. 9), and ultimately into slavery, in payment of debt (2 Kings, iv. 1). Subsequent to the Captivity, the pressure of debts upon the poor became so intolerable that Nehemiah espoused their cause, and insisted on a general remission (Nehem. v.), exacting from the rich an oath that they would never afterwards press for payment.

Both in Greece (Plut. *Vita Solonis*, 15) and in Rome (A. Gell. xx. 1, 19; Liv. ii. 23) the creditor had in early times a right to enforce execution of a judgment for debt against the person of the debtor. Previous to the time of Solon this system, which led to the practical enslavement of insolvent debtors, brought about internal struggles which threatened the existence of the state; and his abolition of it forms one of Solon's many claims to the character of an enlightened legislator. By the Twelve Tables, it was enacted at Rome that if the debtor admitted the debt, or had had judgment pronounced against him for it, thirty days should be allowed him for payment. At the expiration of that period he was liable to be seized by his creditor, who kept him sixty days in chains, exposing him on three market days, and proclaiming his debt. If no *vindex* appeared who made himself responsible for the payment of the debt, if it should prove that there was a valid judgment, the creditor might sell the debtor as a slave. There was also in early Rome a form of contract, known as *nexum*, by which a borrower might 'mancipate' himself to the creditor in security of his debt, the effect being that the creditor, without pursuing any process at law, could, on the failure of the debtor to pay the debt, seize his person and keep him in bondage. Repeated attempts were made by legislation to alleviate the position of *nexi*, the harsh treatment of whom aroused popular discontent. Finally, in 326 B.C., the *Lex Poetilia* liberated all *nexi*, and prohibited the summary seizure of debtors under a nexal contract. It was not, however, till the introduction of *cessio bonorum* by Julius Cæsar in 48 B.C., which permitted a debtor to obtain his discharge on giving up all his property to his creditors, that the relation of creditor and debtor in Rome was put on a satisfactory basis at Rome.

**Debt, NATIONAL.** See NATIONAL DEBT.

**Debussy, CLAUDE ACHILLE**, French composer, was born at St Germain-en-Laye, 22d August 1862. He studied at Paris Conservatorium, where his cantata *L'Enfant Prodigue* won him the Prix de Rome in 1884. Already at this period he brought down upon himself the disapprobation of critics by his disregard of form in *Le Printemps*, a symphonic suite, and in *La Demoiselle Elue*. A visit to Russia brought him under the influence of Russian composers. For long Debussy composed busily without general recognition; but a string quartette and the *Prélude à l'Après-midi d'un Faune* (1894) established his reputation, which was greatly enhanced in 1902 by the production, at the Opéra Comique, of *Pelléas et Mélisande*, founded on Maeterlinck's play. His other works include *Fêtes galantes* (Verlaine), *Poèmes de Baudelaire*, *Images*, *Nocturnes*, and *La Mer*. Debussy deliberately rejects melody as 'almost anti-lyric, and powerless to express constant change of emotion or of life.' He died 25th March 1918.

**Decachord**, an ancient Greek instrument of ten strings (hence the name), triangular in shape; also a kind of large guitar with ten strings.

**Decalogue** (Gr. *dekalogos* = 'the ten words'), the ten commandments. There are two versions of the commandments in the Old Testament—(1) Exodus, xx. 1–17; (2) Deuteronomy, v. 1–21. Though the substance of the commandments is the same

in both these accounts, there are many interesting differences in detail. For instance, the motive for keeping the Sabbath day holy is stated in Exodus thus, 'In six days the Lord God made heaven and earth, . . . and rested the seventh day;' in Deuteronomy, however, the philanthropic motive is introduced, 'that thy man-servant and thy maid-servant may rest as well as thou.' Probably both these versions are derived from an earlier and simpler form which has been lost. It is possible that in this simpler form the Decalogue may have emanated from Moses, but scholars are by no means unanimous upon this point. The Decalogue is universally recognised among Jews and Christians as the embodiment of the fundamental articles of religion and the basal principles of morality. Professor Paterson has described it as 'the charter of ethical piety, the great pre-Christian advocate for righteousness as the highest form of ritual.' Its Divine authority is recognised by Jesus in the Sermon on the Mount (Matt. v. 17), though in many points Jesus deepened and expanded the ethical teaching of the commandments. Moreover, it is quite certain that Jesus did not regard the commandments as exhaustive or as necessarily sufficient by themselves to secure eternal life. When the rich young man, in reply to the question of Jesus, 'Thou knowest the commandments?' said, 'All these have I kept from my youth up,' Jesus did not consider the answer as satisfactory, but added the injunction, 'Sell all that thou hast,' &c. The chief defects of the Decalogue from the point of view of the Christian ideal are: (1) It is too negative. Only two of the commandments are positive, the remaining eight being prohibitions. (2) It is too external. Only the last commandment deals with the motives and inner springs of conduct. The Decalogue is of perpetual value if it be regarded as an elementary guide to religion and conduct. It is a mistake, however, to put it forward as an exhaustive summary of the whole duty of man towards God and his fellows.

There is a diversity of opinion as to the proper division of the commandments. The Greek Church and most Protestant Churches adopt the arrangement in the English Prayer-book. Roman Catholics and Lutherans combine the first two commandments in our ordinary English version into one, and divide our tenth commandment into two. According to the former the ninth commandment runs, 'Thou shalt not covet thy neighbour's wife;' the rest of our commandment constitutes the tenth. According to the Lutherans, however, the ninth consists of the words, 'Thou shalt not covet thy neighbour's house.' See PENTATEUCH; article by W. P. Paterson in *Hastings's Dictionary*; Stanley's *Christian Institutions* (chap. xvii.); Notes on the relevant passages in *Commentaries on Exodus and Deuteronomy*.

**Decameron.** See BOCCACCIO.

**Decamps,** ALEXANDRE-GABRIEL, a celebrated French painter, was born at Paris in 1803. A great portion of his childhood was spent in a lonely part of Picardy among the peasants, which seems to have given him a lifelong distaste for the ways of cultivated society. He studied in a desultory manner under Bouchot, Abel de Pujol, David, and Ingres, but he saw nature in his own way, and stamped the small pictures of animals which he then produced with his own individuality. His want of a thorough grounding in art, and his disinclination for systematic study, told against him, and prevented him from working with perfect ease and mastery. His effects were attained by repeated paintings, and his pictures exhibit a strong impasto, which he scraped with pumice-stone, and again retouched. In 1824 he spent the summer in Switzerland, and in 1827-28 he travelled in Italy and passed to the Levant, where he found

congenial subjects, of the class that Delacroix afterwards treated, which greatly occupied his brush, and which attracted attention in the Salon of 1831. He aspired to treat historical and religious subjects: his 'Defeat of the Cimbri' (1834) attained a great success. He was made a chevalier of the Legion of Honour in 1839, and became officer in 1851. He died at Fontainebleau from a hunting accident, 22d August 1860. His works prove him to have been a powerful colourist; they are effective in composition and the distribution of light and shade, and show a fine appreciation of the wilder and more picturesque aspects of man and nature. Since his death they have realised large prices, his water-colour of 'Children let out of a Turkish School' (1842) fetching 34,000 francs in Paris in 1861. See his *Life* by Moreau (1869).

**De Candolle,** AUGUSTIN PYRAME, an eminent botanist, descended from an ancient noble family of Provence, was born at Geneva, 4th February 1778, and was first drawn to the study of botany by the lectures of Vaucher. In 1796-97 he studied chemistry, physics, and botany in Paris, where in 1797 his earliest work, on lichens, was published. Other works quickly followed, including his *Astragalologia* (1802), and his valuable *Essais sur les Propriétés Médicales des Plantes* (1804). In 1802 he was elected to an honorary professorship in the Academy of Geneva, but remained in Paris, and delivered his first botanical lectures in the Collège de France in 1804. His *Flore Française* appeared in four volumes in 1805. Employed by the government, he visited all parts of France and Italy in 1806-12, investigating their botany and agriculture. The results of his journeys are partly embodied in a supplement to the *Flore*. He was appointed in 1807 to a chair at Montpellier, where he lived from 1810 to 1816; he then retired to Geneva, where a professorship of Botany was founded for him, and where he spent the remainder of his life. He died 9th September 1841. De Candolle was an industrious writer, and the fruits of his valuable studies in systematic botany and the properties and natural affinities of plants are embodied in a considerable number of works. The greatest of these, his *Regni Vegetabilis Systema Naturale* (vols. i. and ii. Paris, 1818-21), was commenced on too grand a scale, and was continued within more reasonable limits in the *Prodromus Systematis Naturalis Regni Vegetabilis* (17 vols. 1824-73, the last ten by his son and others). De Candolle bequeathed his collections—including a herbarium of more than 70,000 species of plants—to his son, ALPHONSE DE CANDOLLE (1806-93), on condition of his keeping them open to the public, and of his carrying on the *Prodromus*. That son, himself a botanist of no mean fame, published several works of note, the most important being *Géographie Botanique* (2 vols. 1855) and *Origine des Plantes Cultivées* (1883). He also edited the *Mémoires* of his father (1862).

**Decapoda.** See CRUSTACEA, CEPHALOPODA.

**Decapolis.** See KERAKE, PALESTINE.

**Decatur,** capital of Macon county, Illinois, on the Sangamon River, 39 miles E. of Springfield, at the junction of several railways. It has woollen, planing, and flour mills, and a vast variety of other factories. Pop. (1880) 9547; (1920) 43,818.

**Decatur,** STEPHEN, American naval commander, was born in Sinnepuxent, Maryland, 5th January 1779, of French descent, and obtained a midshipman's warrant in 1798. He saw some service against the French, and was commissioned lieutenant in the following year; and at the close of the French war in 1801 he was one of the thirty-six officers of that rank retained in

the reduced strength of the navy. In the war with Tripoli (1801-5) he gained great distinction; his brilliant achievement of boarding and burning the captured *Philadelphia* in the harbour of Tripoli, and then escaping under the fire of 141 guns, Nelson pronounced 'the most daring act of the age.' For this he received his commission as captain in 1804; in 1810 he was appointed commodore. In the war with England in 1812 he captured the frigate *Macedonian*, but in 1814 he was obliged to surrender, after a resistance that cost him a fourth of his crew, to four British frigates. In 1815 he chastised the Algerines for their piracy, and compelled the dey to declare the American flag inviolable; and he obtained indemnities for violating treaty stipulations from the bey of Tunis and the pasha of Tripoli. He was appointed a navy commissioner in 1816, and was killed in a duel by Commodore James Barron, near Bladensburg, Maryland, 22d March 1820.

**De Caus.** See CAUS.

**Decazeville**, a town in the French department of Aveyron, 110 miles NNE. of Toulouse by rail, with iron and coal mines and extensive blast-furnaces and ironworks; pop. 14,000.

**Deccan** (*Dakshin*, 'the south'), a term applied sometimes to the whole of the Indian peninsula south of the Vindhya Mountains, which separate it from the basin of the Ganges, and sometimes restricted to that portion of the same which is rather vaguely bounded on the north by the Nerbudda, falling into the Gulf of Cambay, and on the south by the Kistna or Krishna, flowing into the Bay of Bengal. The name, like that of the Carnatic (q.v.), is rather of historical interest than of actual use. See J. D. B. Gribble, *History of the Deccan* (vol. i. 1896; vol. ii., ed. by the author's daughter, Mrs Pendlebury, 1925).

**Deceased Wife's Sister.** By the laws of the United Kingdom, marriage with a deceased wife's sister was till 1907 prohibited as incestuous. At one period this was the universal law of Christendom—both branches of the Christian church, the Eastern as well as the Western, having united in condemning it. The early canon law forbade marriages between relatives to the seventh degree (afterwards changed to the fourth degree by the Lateran council 1215 A.D.), and declared that affinity must be treated in the same way as consanguinity (see CONSANGUINITY). The professed foundation for this was the Mosaic law respecting the intermarrying of kindred, as given in Leviticus, xviii. As is well known, however, the canon law was not at all times stringently enforced in this respect by the ecclesiastical courts, and we find that papal dispensations—a fruitful source of revenue to the church—were not uncommon at certain periods of history. A noted historical instance is the case of Henry VIII. and Catharine of Aragon. The opinion of the 19th century, however, ran counter to the canon law on the subject, as adopted by the Reformed Churches; and the law prohibiting marriages with a brother's widow or a deceased wife's sister has been abrogated in every state on the continent of Europe, in the United States, and in most, if not all, the British colonies. Great Britain, however, adhered to the old rule till 1907, and till 1921 excluded marriage with a brother's widow.

In England, though marriage with a deceased wife's sister seems to have been voidable at common law, it was first prohibited by an act passed in the reign of Henry VIII. (25 Henry VIII. chap. 22). The force of this enactment was, however, somewhat weakened by another statute in the following year declaring that 'all lawful persons may marry.' The combined effect of these

statutes and the common law continued to be a subject of dispute among lawyers down to the passing of Lord Lyndhurst's Act, 1835. The better opinion seems to be that down to 1835 such marriages were binding till they were annulled by decree of the ecclesiastical courts, and therefore if either of the parties died before decree was obtained, the children of the marriage were legitimate, and entitled to inherit, and such marriages were not uncommon. But Lord Lyndhurst's Act declared all such marriages entered into after its date to be *ipso facto* null and of no effect.

In Scotland, by the Act 1567, chaps. 14 and 15, all connections supposed to be expressly prohibited by the divine law in the 18th chapter of Leviticus are declared incestuous, and punishable by death. The declaration of the Confession of Faith follows in this matter the canon law as fixed by the Lateran council above mentioned. According to the interpretation which this Act of 1567 received from the judges, it applied to marriages with a deceased wife's sister. Barbara Tannahill, in the beginning of the 18th century, was executed on her own judicial confession for having had connection with the husband of her deceased sister. In punishing the offence criminally, the Scottish law was more stringent than the English, incest not having been *per se* a crime in England till 1908 (8 Edw. VII. chap. 45).

Organised agitation in Great Britain for the abolition of the law respecting marriage with a deceased wife's sister dates back almost to the time of Lord Lyndhurst's Act. The matter was first brought before parliament in 1841, in which year leave was refused by the House of Commons for the introduction of a bill for the repeal of the law. Thereafter the subject was brought constantly before parliament. When the bill for repealing the law passed in the Commons in 1907, it had been previously passed there eighteen times.

In Great Britain the churches opposed legislation, the former law being, as above stated, professedly based upon Leviticus, xviii. 18. The interpretation of this text has given rise to diversity of opinion. The better opinion is that the prohibition refers only to marriage during the lifetime of the wife; and, in particular, this view of the text has been taken by the most learned Jewish rabbis. In the Book of Deuteronomy the Jewish law seems to have allowed and even commanded marriage with a deceased husband's brother, and it seemed hardly reasonable to suppose that one was permitted and the other prohibited, though the converse held in Great Britain from 1907 to 1921.

Marriage with a deceased husband's brother remained null and void until the passing of the Deceased Brother's Widow's Marriage Act, 1921.

A clergyman is not bound to allow the use of his church for such marriages, but *may* (the act says 'may' not 'must') permit another clergyman, entitled to officiate within the diocese, to perform the marriage service. A clergyman of the Church of England is still liable to ecclesiastical censure for marrying his deceased wife's sister.

The Act of 1907 does not affect decrees of nullity made before its date, nor does it affect marriages contracted before its passing, which were valid at the time of marriage, e.g. where a man who had married his deceased wife's sister had, before the passing of the act, married another woman in her lifetime. But sect. 1 has a retrospective effect, legitimating all children of marriages with a deceased wife's sister whenever contracted.

Sect. 2 of the act contains a saving of existing rights and interests and of claims by the crown for death-duties payable before the passing of the act. The editor of Chitty's Statutes observes, 'The effect is that though the void marriage is by sect. 1

rendered valid, the results of such void marriage are not to be interfered with.'

Sect. 3 provides, in effect, that adultery with a wife's sister shall still be a ground of divorce, without it being necessary for the injured wife to prove cruelty. Accordingly, as has been said, 'this extraordinary result is arrived at, namely, that adultery with a wife's sister is incestuous, but upon the wife's death "incest" ceases by virtue of sect. 1.' This sect. 3 also provides that 'it shall not be lawful for a man to marry the sister of his divorced wife, or of his wife by whom he has been divorced, during the lifetime of such wife.'

The word 'sister' in the act includes a sister of the half-blood.

Finally, it should be noticed that by the Colonial Marriages (Deceased Wife's Sister) Act, 1906 (6 Edw. VII. chap. 30) it is provided that 'where a man has, whether before or after the passing of this act, married his deceased wife's sister, and at the date of the marriage each of the parties was domiciled in a part of the British possessions in which at that date such a marriage was legal, the marriage, if legal in other respects, shall be, and shall be deemed always to have been, legal for all purposes, including the right of succession to real property and to honours and dignities, within the United Kingdom, unless either party to the marriage has subsequently, during the life of the other, but before the passing of this act, lawfully married another.' There is a saving for rights accrued before the act.

**December**, the last month of the year. In the old Roman calendar, before the time of Julius Cæsar, the year began with March, and that which is now the twelfth was then the tenth month; hence the name (*decem*, 'ten').

**Decemvirs** (*decemviri*, 'ten men'), a body of ten commissioners, the ten men appointed to codify the law, both public and private, at Rome. Commissioners were first sent to Greece to study the Greek statute law, and on their return (451 B.C.) all the magistracies were suspended, and a commission of ten patricians (*decemviri legibus scribendis*) appointed with consular powers to reduce the laws to writing. By the end of the next year the code was finished, and after being ratified by the comitia of the centuries, was erected in the Forum inscribed on ten tables of wood. Next year the decemvirate was renewed, and the result of their deliberations was to add two other supplemental tables, from which the whole code bore its official title of the laws of the Twelve Tables (q.v.). The president of both the decemvirates was the notorious Appius Claudius (q.v.).

**Deception Island**, a volcanic island belonging to the South Shetland group in the Antarctic Ocean, directly south of Cape Horn. Amidst its ice-covered rocks lies a crater-lake, 5 miles in circumference, surrounded by hot springs.

**Déchelette**, JOSEPH, French archæologist, born in 1862 at Roanne, wrote an important but unfinished *Manuel d'Archéologie préhistorique, celtique, et gallo-romaine* (1908-14), and other works. He was killed in action on the Aisne.

**Deciduous Trees** are those which annually lose and renew their leaves before next year's leaves appear. In cold and temperate countries the fall of the leaf in autumn, and the restoration of verdure to the woods in spring, are among the most familiar phenomena of nature, connecting themselves also very intimately with the feelings, habits, and circumstances of mankind. The greater part of the trees and shrubs of temperate regions are deciduous; but within the tropics the forest retains always its luxuriance of foliage, except in countries

where the dry season is extremely marked. There many trees lose their leaves in the dry season, and exhibit the same partial suspension of vegetative life. Trees not deciduous are called Evergreen (q.v.). The means of disarticulation of deciduous leaves is described under LEAF.

**Decimal Fractions** (Lat. *decem*, 'ten') are such as have for their denominator any of the numbers 10, 100, 1000, &c.—i.e. any power of ten (see FRACTION). Thus,  $\frac{7}{10}$ ,  $\frac{13}{100}$ ,  $\frac{17}{1000}$ , are decimal fractions. In writing these the denominator is conventionally omitted, and the fractions expressed thus: 0·7 or ·7, ·23, ·019. That these numbers do not express integers is intimated by the point to the left; and the denominator is always 1, with as many ciphers annexed as there are figures in the decimal. In the third example a cipher is prefixed to 19, because otherwise it would read as if it stood for  $\frac{19}{10}$ . The expression £5·647 is read, Five pounds and 647-thousandths of a pound; or, Five pounds, and six-tenths, four-hundredths, and seven-thousandths of a pound. That these two readings are equivalent appears from this, that  $\frac{19}{10} = \frac{190}{100} + \frac{17}{1000} + \frac{170}{1000} = \frac{19}{10} + \frac{17}{100} + \frac{17}{1000}$ . It thus appears that the first figure of a decimal to the right of the point expresses tenths of the unit; the second, hundredths; the third, thousandths, &c. In this property lies the great advantage of decimal fractions; they form merely a continuation of the system of notation for integers, and undergo the common operations of addition, multiplication, &c., exactly as integers do. To explain the principles which determine the position of the decimal point after these operations belongs to a treatise on arithmetic.

The disadvantage attending decimal fractions is, that comparatively few fractional quantities or remainders can be exactly expressed by them; in other words, the greater number of common fractions cannot be reduced, as it is called, to decimal fractions, without leaving a remainder. Common fractions, such as  $\frac{1}{2}$ ,  $\frac{1}{3}$ ,  $\frac{1}{4}$ ,  $\frac{1}{5}$ ,  $\frac{1}{6}$ , for instance, can be reduced to decimal fractions only by multiplying the numerator and denominator of each by such a number as will convert the denominator into 10, or 100, 1000, &c. (The common process is merely an abridgment of this.) But that is possible only where the denominator divides 10, or 100, &c., without remainder. Thus, of the above denominators, 2 is contained in 10, 5 times; 4 in 100, 25 times; and 25 in 100, 4 times; there-

fore,  $\frac{1}{2} = \frac{1 \times 5}{2 \times 5} = \frac{5}{10} = \cdot 5$ ;  $\frac{1}{4} = \frac{1 \times 25}{4 \times 25} = \frac{25}{100} = \cdot 25$ ;  $\frac{9}{25} = \frac{9 \times 4}{25 \times 4} = \frac{36}{100} = \cdot 36$ . But neither 3 nor

7 will divide 10 or any power of 10; and therefore these numbers cannot produce powers of 10 by multiplication. In such cases, therefore, and in fact in the case of any vulgar fraction (in its lowest terms) whose denominator contains any other prime factor than 2 or 5, an equivalent decimal cannot be found. If we try to find it, the result is an infinite series, which is called a repeating, recurring, or circulating decimal. Thus  $\frac{1}{3} = \cdot 6666$ , &c., where the 6 repeats for ever—i.e.  $\frac{1}{3}$  cannot be expressed as a decimal. The non-terminating result, '666, &c., is written  $\cdot 6$ .

**Decimal System**. This name is applied to any system of weights, measures, money, &c., in which the standard unit is divided into tenths, hundredths, &c., for the denominations below it, and multiplied by 10, 100, &c., for those above it. The nature of this method of division will be best explained by an example from the French system, where it has been most rigidly carried out. The

*metre* (=39·37 English inches nearly) is the unit of length, and the foundation of the whole system. For the higher denominations of length the Greek prefixes *deca*, *hecto*, *kilo*, and *myria* are prefixed to signify multiplying by 10, 100, 1000, 10,000; so that *decametre*=10 metres, *kilometre*=1000 metres, &c. The Latin prefixes *deci*, *centi*, *milli*, on the other hand, are used to express division by 10, 100, &c. Thus *decimetre*= $\frac{1}{10}$  of a metre, *centimetre*= $\frac{1}{100}$  of a metre, &c. For money, the *franc* being the unit, a *décime* is the tenth part of a franc; and a *centime*, the hundredth part.

In 1865 Belgium and Switzerland adopted the French decimal system of money, weights, and measures. Afterwards the Italian *lira*, the Greek *drachmè*, the Spanish *peseta*, and more recently the Rumanian *lei*, and the Serbian *dinar*, were assimilated to the *franc*. Other countries, though retaining each its own special unit coin, divide it into 100 parts—viz. Germany, Austria, Russia, and the United States of America. Many countries have adopted the metrical system of weights and measures, though rejecting the franc.

The method of decimal gradation in weights and measures naturally suggests itself to the arithmetician, on account of the *language* of numbers, and the Arabic notation. Practical legislators, however, have pronounced the number *ten* to be most unsuitable as a basis, especially for the purposes of 'retail trade.'

In 1821, after an able report drawn up by John Quincy Adams, the United States government rejected the metrical system as unsuited to practical life. The question of adopting the French scheme has also been repeatedly discussed in the House of Commons, but though many, in the interests of scientific pursuits and international transactions, advocated a change, there are difficulties in the way of uprooting our existing method, with its excellent supply of binary factors. A Royal Commission reported against change in 1920. Although proposed in 1795, the decimal system in France required repeated legislation before it could gain footing, and though it was made obligatory from 1st January 1840, the people still retain traces of the older modes of computation. The centesimal division of the right angle into grades and of these into minutes was also proposed at the French Revolution, but had long been abandoned, even in France, when it was officially adopted in Sweden in 1921. It was also used as a basis in dividing the thermometric scale, but Fahrenheit's is often preferred to the centigrade, because there are more subdivisions, and because it avoids the use of negative numbers. The application of the system to the division of time was so unworkable as scarcely to tolerate even a trial. There, as elsewhere, the duodecimal mode, as compared with the decimal, is incontestably superior. For the decimal system in numerical notation, see SCALES OF NOTATION, NUMERALS; and for the system of measurements based on the metre, see METRE.

**Decimation**, a Roman military punishment, whereby when a considerable body of troops committed some grave military offence, which would be punished with death in an individual, the punishment was awarded to one-tenth of them by lot, instead of to the whole number, that so the army might not be too much weakened. The practice was borrowed from the Romans by Essex at Dublin (1599), by the Austrians at Leipzig (1642), and by the French at Trèves (1675); but Blücher tried vainly to employ it against the mutinous Saxon battalions at Liege (1815).

**Decius**, a Roman emperor, whose name in full was C. MESSIUS QUINTUS TRAJANUS DECIUS. He was born at Budalia, in Lower Pannonia, towards

the close of the 2d century, and was sent in 249 by the Emperor Philipppus to reduce to subordination the rebellious army of Mœsia. The soldiers proclaimed him emperor against his will, and forced him to march upon Italy. Philipppus encountered the forces of Decius near Verona, but was defeated and slain. Decius assumed the government of the empire in the end of the year 249, but his brief reign was one of restless warring with the Goths, fighting against whom he was killed near Abricium in the close of the year 251. In his reign the Christians were persecuted with great severity. At Rome, Antioch, and Jerusalem the bishops were massacred, the great Origen was cruelly tortured, and dreadful cruelties were perpetrated at Alexandria.

**Deck**. In ship construction a deck is a platform extending from one side of a vessel to the other, laid on the top of the beams which connect the sides of the vessel together. Except in very small vessels, there are more decks than one. Each deck forms a flooring for the cargo, or passengers and crew accommodated thereon, and a covering for the deck below it. The several decks are further supported one over the other by iron or steel pillars secured to the beams, and by the transverse bulkheads which form watertight and other divisions.

A deck generally has a certain amount of 'camber' or athwartship round, not only to drain water to the ship's side, but to contribute to the strength of the deck beams. The deck is also 'sheered' forward and aft, to raise the ends higher above the water.

Vessels are described by the number of complete decks that are 'laid and caulked.' A 'three-decked' ship has 'upper,' 'main' or 'middle,' and 'lower' decks; but, in addition, there may be an 'orlop' deck, depending on the depth of the vessel.

Again, certain vessels are distinguished by some characteristic deck. A 'spar-decked' vessel is similar to a three-decked vessel of the same dimensions, but is lighter in construction. The spar deck corresponds to the upper deck. An 'awning-decked' vessel is one having a comparatively light superstructure, above the main deck proper, forming a complete deck, which is intended to shelter passengers or cattle, or for the conveyance of cargo either light in its nature or limited in quantity.

Above the upper deck there are generally superstructures which do not extend the full length of the vessel, and which form partial decks: the 'forecastle' deck (either 'sunk' or 'top-gallant') being at the fore end of the vessel; the 'bridge' deck about the mid-length; and the raised 'quarter'-deck and the 'poop'-deck at the aft end. In large passenger vessels there may also be a 'promenade' deck and a 'boat' deck.

Depending on size, vessels have one or more steel decks fitted, with the wood longitudinal planking on the top.

The spaces between the several decks are spoken of as 'tween decks.'

Modern vessels have so increased in size, and have so many decks, that Lloyd's Register of Shipping have now abandoned the foregoing names to the various complete decks, simply numbering them instead. See also SHIPBUILDING, NAVY. For deck cargoes, see PLIMSOLL.

**Decken**, KARL KLAUS VON DER, an ill-fated African traveller, was born 8th August 1833, at Kotzen, in the Mark of Brandenburg, passed from the gymnasium of Lüneburg, and the cadets' college at Hanover, into the Hanoverian army, which he left after ten years' service (1860) to follow his bent towards travel. On Baith's advice he went to Zanzibar, and started thence on a

journey to Lake Nyasa, which failed through the treachery of his Arab guide. In 1861 he started on a second and successful journey to the mountain-regions of Kilima-Njaro. In the following year, with O. Kersten, he climbed that mountain to the height of 13,780 feet. In 1863 he made an extensive voyage along the east coast of Africa, after which he returned to Europe to plan a great expedition for the exploration of East African rivers. This journey ended in disaster, and Decken was murdered by a Somali on the 25th September 1865. Only five Europeans and six negroes of his company managed to reach Zanzibar. See Kersten's *Von der Decken's Reisen in Ostafrika* (4 vols. 1869-79).

**Decker, SIR MATTHEW**, a political economist, was born at Amsterdam in 1679. He came to London in 1702, and having embarked in commerce, attained the greatest success; received a baronetcy in 1716, and subsequently sat in parliament. He died 18th March 1749. He published anonymously two pamphlets which were much discussed: one (in 1743) proposed to raise all the public supplies from a tax upon houses; the other, on the decline of Britain's foreign trade (1744), contained many good arguments for free trade.

**Decker, THOMAS.** See DEKKER.

**Declaration**, in Criminal Proceedings. In Scotland, the prisoner's statement before the magistrate (or sheriff) is called his declaration. It is the duty of the magistrate to take this declaration immediately on the prisoner's being brought to him—that is to say, if the prisoner is in his sober senses; but under the Criminal Procedure (Scotland) Act, 1887, the magistrate has power to postpone the examination to a time not later than forty-eight hours after arrest, in order to give opportunity for the legal adviser of the prisoner to appear. Before the examination the prisoner is entitled to have a private interview with his legal adviser, who may be present during the examination. The magistrate must previously inform the prisoner that it is entirely at his own option to declare or not, but that if he chooses to declare, the declaration may be used in evidence against him on his trial. In practice the examination is generally conducted by the procurator-fiscal. The declaration ought to contain the name, age, and designation of the prisoner, the parish and county in which the crime is said to have been committed, and all similar particulars. When completed it must be read over to the prisoner, who, if he is able to write, signs every page of it along with the magistrate. If he cannot or will not write, the magistrate signs it in his stead. There must, moreover, be two witnesses present, who shall sign the declaration, and who, if necessary, can speak to the manner in which it was taken. If the prisoner does not understand English, a sworn interpreter must be employed. The declaration cannot be produced as evidence if the magistrate has delegated the duty of taking it to his clerk, or to any one not a magistrate.

In the United States, when a person is arrested for a felony, the magistrate before whom he is brought takes the statement of the accused prior to the commitment if he desires to make one. The magistrate must act in person, and the prisoner must understand that he may or may not make the statement, and that it may be used against him upon his trial. If he cannot write, or refuses to write, the magistrate must not write his name for him; if he signs it he must first have the opportunity of reading it himself, but may waive his right to read it and ask the magistrate to read it to him. The magistrate may ask questions to bring out the facts. The mode of

taking the statement or declaration is in general regulated by statute, and may form a part of the preliminary examination. If taken according to the prescribed forms of law, and as a spontaneous admission of guilt, it is termed a judicial confession upon which an indictment may be found. See CRIMINAL LAW.

**Declaration**, in Common Law, was the pleading in which the plaintiff in an action at law set forth his case against the defendant. Since the Judicature Act of 1875, the *Statement of Claim* (q.v.) takes the place both of it and of the former *Bill in Chancery* (see BILL). In the United States the declaration still retains many of the features of the English common-law declaration, but this form is gradually falling into disuse in obedience to the modern tendency to simplify judicial proceedings. Many of the states having adopted one form of civil action, the courts of law have simplified the common-law declaration and adapted it to this form of action. The declaration substituted must be entitled of the court, term, and number, the venue laid, the names of the parties, and the facts necessary to show jurisdiction stated. This is followed by a concise statement in narrative form of the entire cause of action showing the right of plaintiff to recover.

**Declaration**, in lieu of an oath. See AFFIRMATION, OATH. In the United States, the form of an oath is immaterial, provided it be such as the witness believes is binding upon his conscience. It is essential that the oath, declaration, or affirmation be administered in a manner prescribed by law. Mere technical variations do not affect the validity of an oath, and verbal deviations are immaterial. Perjury may be committed although the person was improperly sworn. No person will be permitted to make a declaration or affirmation unless he has conscientious scruples against swearing or taking an oath. Declaration in lieu of an oath or affirmation is becoming very general throughout the United States.

**Declaration, DYING.** The rule that secondary or hearsay evidence is inadmissible suffers an exception, both in England and Scotland, in the case of a declaration made by a person convinced of his impending death, and who does not survive the trial of the accused. In cases of murder, the dying declaration of the victim as to the circumstances of the crime is always admitted as evidence on the trial of the prisoner, provided that it was deliberately emitted while the deceased was in possession of his faculties, and that it is proved by credible witnesses. In Scotland, the dying declaration of a witness is admissible even though he is not himself conscious of the danger of death, but in the United States the English rule is followed, and the declarant must have abandoned all hope of recovery from the injury inflicted by the accused. In Scotland, while a declaration is usually taken officially and on oath, it is admissible unsworn, if freely emitted and taken by some 'credible person.' The principle under which the dying declaration is admitted is that the awful situation of the dying person is as powerful over his conscience as the obligation of an oath, and does away with all motive to disguise the truth. Accordingly the person against whom a dying declaration is put in evidence may be allowed to show that the deceased was not of such a character as to feel the religious obligation of his situation. A dying declaration may be adduced for as well as against a person accused of crime; and there are cases on record in which persons charged with murder have been successfully exculpated by this kind of evidence.

**Declaration of Rights.** See RIGHTS.

**Declaration of War.** See ENEMY.

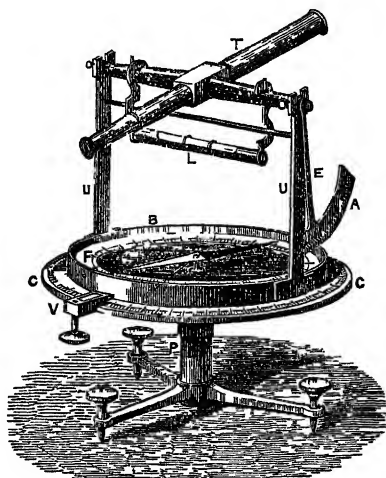

**Declarator.** See ACTION.

**Declension**, a grammatical term applied by the ancient grammarians to the system of modifications called *cases*, which in many languages nouns, pronouns, and adjectives undergo to indicate the various relations in which they stand to other words. The word *Case* means 'falling'; *Declension*, a 'sloping down'; and were applied because that form of a noun used as the subject of a sentence was supposed to be represented by an upright line, and the other forms by lines falling or sloping off from this upright line at different angles. Hence a collection of the various forms which a noun might assume formed the *declension* or *sloping down* of the noun. The English language has no proper declensions at all, having no cases but the genitive, and some traces of a dative, accusative and instrumental. Sanskrit had eight cases; Latin, six; and Greek, five. Groups of nouns forming their case-endings in the same way are called declensions. Thus Latin nouns are said to be divided into five declensions. The Latin cases are the Nominative, which names the subject or actor; the Genitive, expressing the source whence something proceeds, or to which it belongs; the Dative, that to which something is given, or for which it is done; the Accusative, the object towards which an action is directed; the Vocative, the person addressed or called; and the Ablative, that from which something is taken. The Greek has no Ablative case, while the two additional cases of Sanskrit are an Instrumental case, and a Locative case. In time case-endings become rubbed off, and prepositions are used in their stead, thus French and Italian have lost all the Latin cases of nouns and adjectives. Languages of the agglutinating order have, in general, a great abundance of cases. Thus Finnish nouns have fifteen cases; and in Magyar as many as twenty cases may be reckoned. See GRAMMAR and PHILOLOGY.

**Declination.** If a great circle be drawn through the pole of the heavens and any star, the declination of the star is the portion of the circle intercepted between the star and the equator (see POLE). The place of a point in the heavens is determined by its *right ascension* and *declination*, just as a point in the earth's surface is determined by its latitude and longitude.

**Declination Needle**, or DECLINOMETER. The magnetic meridian passing through any place on the earth's surface is a vertical plane whose direction is that in which a magnetic needle, free to move about a vertical axis, comes to rest under the influence of the earth's magnetic force. In general, the magnetic and geographical (or astronomical) meridians are not coincident; the angle between is termed the magnetic declination, or (in nautical phraseology) the variation. It is east or west, according as the magnetic is east or west of the geographical meridian. Any apparatus for the measurement of this angle is termed a declinometer, and consists essentially of a means of ascertaining the two necessary elements—viz. the directions, at the place of observation, of the two meridians. The accompanying figure represents one such instrument, the declination needle or compass. Upon a tripod, provided with levelling screws, stands the pillar P, to which is fixed the graduated circle CC. The compass-box B, with the attached vernier V, moves on the azimuthal circle by means of a pivot on the pillar P. Two uprights, U, U, are fixed to the side of the compass-box, on the tops of which rests the axis of the telescope T. A graduated arc, A, is fixed to the bottom of one of the uprights, and the angle of elevation of the

telescope is marked by the vernier on the aim E, attached to the axis of the telescope, on which is hung the level L, for adjusting the instrument previous to making an observation. Inside the compass-box is another graduated circle F, the line joining the zero-points of which is parallel to the axis of the telescope. The compass-box and telescope thus move round together on an axis passing through the centre of the azimuthal circle. When an observation is made, the instrument is first of all levelled, and the telescope directed to a star which is either on the astronomical meridian or whose position with respect to it is known. The

Declination Needle.

reading of the inner circle then gives the declination at once, in the former case; if the latter—i.e. if the star be not on the meridian, the reading of the inner circle has to be corrected by adding or subtracting, as the case may be, the position of the star in azimuth, in order to give the declination. In order to obviate error due to the non-coincidence of the magnetic and geometric axes of the needle, a second reading is taken with the face of the needle reversed; the mean of the two readings is taken as the true declination.

It is found, however, that this instrument only gives results approximately correct, and has in consequence been superseded in observatories and magnetic surveys by a form of the unifilar magnetometer. For an account of the determination of declination by this latter instrument, see MAGNETOMETER. Details as to the value and secular change of the declination at different places on the earth's surface will be found under MAGNETISM.

**Decoction**, the term applied in pharmacy to the solution procured by boiling an organic substance with water.

**Decolorimeter**, an instrument for determining the power of portions of bone-black or animal charcoal to abstract colouring matter. See CHARCOAL.

**Decomposition** is the rather comprehensive term applied to the breaking up of complex substances, or substances of delicate stability, into others which are less complex or more stable. Such breaking up is very familiar in many chemical changes, and may result from increase of temperature, the action of light, the action of ferments and micro-organisms, and so on. The ordinary process of alcoholic fermentation is a good example of decomposition, which takes place in the presence

of, and is dependent upon, the life and growth of yeast in the saccharine solution. Similarly the oxidation of nitrogenous organic matters with formation of nitrates, if not dependent upon, is greatly accelerated by the presence of a micro-organism.

The term decomposition is constantly applied in chemistry to the changes which compounds undergo in the most varied circumstances when subjected to change of conditions. See also CHEMISTRY, FERMENTATION, PUTREFACTION.

**Decomposition of Forces.** See COMPOSITION.

**Decorated Style** of Gothic Architecture prevailed in England during the reigns of the first three Edwards, or from towards the close of the 13th till near the end of the 14th century. Under **GOthic ARCHITECTURE** it will be shown

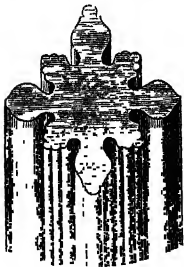

Fig. 1.—Column, Collegiate Church, Manchester, 14th century

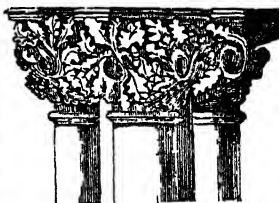

Fig. 2.—Decorated Capital, York Cathedral.

how the pointed style progressed, and was naturally and logically developed in all its elements, constructional as well as decorative, until skill in execution exceeded originality in design, after

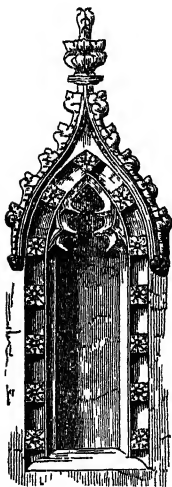

Fig. 3.—Niche, Walpole St Andrews, Norfolk, 14th century.

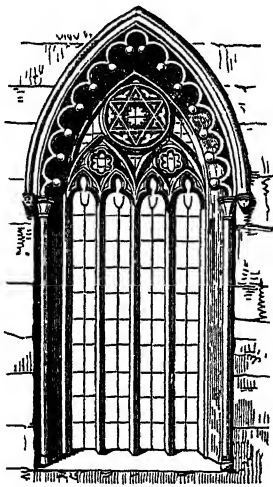

Fig. 4.—Window, Broughton, Oxfordshire, 1300.

which the art gradually deteriorated. The Decorated or second pointed style occupies the position in which these two elements were in full accord and completest development. Hence this is invariably considered the perfect period of Gothic Architecture.

In the Decorated style the simple forms of the early pointed became more complex. The simple roll is divided into two parts, the mouldings are more numerous and refined, and they are beautifully grouped and proportioned. The pilastrs consist similarly of clustered shafts or mouldings arranged commonly on a lozenge plan (fig. 1). The caps are usually carved in imitation of natural foliage, and partake of the character of wreaths growing round the caps, instead of springing from the neck-moulding as in the preceding style (fig. 2). The buttresses are encircled with niches and canopies, and the latter are more elaborately decorated than formerly. The drip-mouldings over doors, windows, niches, &c. are crocketed and formed into an ogee curve at the top, and finished with a finial—in short, every detail is elaborated and richly decorated. But this development is most prominently marked in the tracery of the windows. In the first pointed style this feature is of the simplest character; but in the Decorated it becomes fully developed, and forms the most prominent characteristic of the style. At first the tracery consists of geometric figures, such as circles, trefoils, &c.; but in the later examples it develops into flowing lines, which in France passed into the 'Flamboyant' (q.v.). This development of the tracery led to the enlargement of the windows, in order to afford space for its exhibition. Large circular windows, filled with tracery, were also introduced (see WINDOW). The early ornaments became refined, as, for instance, the dog-tooth was enriched into a four-leaved flower, and the ball-flower is also of frequent use. Segmental arches and square lintels are occasionally employed. In the beginning of the 15th century the Decorated gradually passed into the Perpendicular style.

**Decoration Day**, in the United States, is the 30th of May, on which day the graves of soldiers are visited, and flowers deposited thereon by surviving comrades.

**Decorations.** See ORDERS OF KNIGHTHOOD, MEDAL.

**Decort**, FRANS, a Flemish lyrical poet, born at Antwerp, 21st June 1834. At first he was engaged in trade, later he edited newspapers, was secretary to a steamship company, and became in 1861 secretary to the general auditor in the Cour Militaire at Brussels, where he died, 18th January 1878. Decort's poetry deals mainly with the simple joys and sorrows of the family hearth, but it does not lack passion and power. For some years he issued at Antwerp a very popular almanac, *Jan en Alleman*. Various collections of his poems were *Liederen* (2 vols. 1857–59), *Zingzang* (1866), and *Liederen* (1868). He did a fine Flemish translation of some of Burns's songs (1862).

**De Coster**, CHARLES, Belgian writer, in French, was born 20th August 1827 at Munich. He was employed in a bank at Brussels for some time, and then studied (1850–55) in Brussels university. His *Legendes flamandes* appeared in 1857; *Contes brabantines* in 1861. Ten years of work went to his masterpiece, *La Légende de Thyl Ulenspiegel et de Lamme Goedzak* (1867), a prose epic of the resurgence of Flemish nationality in the days of Spanish tyranny, borrowing its story from the German *Till Eulenspiegel* and its language from Rabelais, but full of the spirit of Flanders. De Coster was professor of history and French literature in Brussels military academy from 1870, and died 7th May 1879. His books, illustrated by Félicien Rops and others, were in his lifetime and for long after comparatively little read or appreciated, but *Uelenspiegel* is now recognised as one of the greatest achievements of Belgium in literature. An abridged translation into English was done by G. Whitworth

in 1918; a complete one by F. M. Atkinson in 1922.

**Decoy.** See WILD-FOWL.

**Decoying of Children.** See ABDUCTION, KIDNAPPING.

**Decree**, or, as it is frequently called in Scotland, a Decreet, is a final judgment of a court, whereby the question at issue is set at rest. In England, it used to be commonly applied to the final judgments of courts of equity. For a *decree nisi*, see DIVORCE. *Decree in absence*, in Scotland, is equivalent to a judgment by default in a common-law court.

In the United States, a decree is the order or judgment of a court of equity, admiralty, or a common-law court with equity powers. It may be either final or interlocutory, and is conclusive if all parties in interest have been served with proper notice. It cannot be set aside by an act of congress or the state legislature. By the United States Constitution, the decrees of a competent court having full jurisdiction in one state are equally binding in every other state, and must be received in evidence in all the courts of the United States.

**Decree**, in Theology. See PREDESTINATION.

**Decrepitation**, the crackling sound heard when a substance like common salt is thrown upon a fire. A series of minute explosions occur, owing to the water between the plates of the crystalline particles becoming expanded by the heat, and ultimately bursting them.

**Decretals.** See CANON LAW.

**Dédéagach** (Gk. *Alexandropolis*), an Ægean seaport of Greece, Turkish till 1913-14, Bulgarian till 1919, about 10 miles NW. of the mouth of the Maritza. It has a considerable trade, and railway connection with Constantinople, Salonika, and Bulgaria. Pop. 7000.

**Deduction**, in Logic, as opposed to Induction (q.v.), is the method of reasoning from generals to particulars, as the latter is from particulars to generals. *Induction* is the mode by which all the materials of knowledge are brought to the mind and analysed; *Deduction*, the process by which the knowledge thus acquired is utilised, and by which new and more complicated inductions are rendered possible. See INDUCTION, LOGIC.

**Dee**, a Welsh and English river, issuing from Bala Lake, in Merionethshire, and flowing NE., N., and NW. to the Irish Sea. Near Trevor it is crossed by the Ellesmere Canal, on an aqueduct 1007 feet long and 120 high; and also by the stone viaduct of the Chester and Shrewsbury Railway, of 19 arches, each 90 feet span and 150 high. Below Trevor it winds first south-east, and then north-east and north to Chester, which city it nearly encircles. At Chester (q.v.) it is 100 yards broad, and thence runs alongside marshes in an artificial tidal canal 7 miles long, which should admit ships of 600 tons, but which in the autumn of 1888 was reported to be rapidly silting up. Near Connah's Quay, between Chester and Flint, where its width is 160 yards, it is crossed by the great railway swing-bridge, whose first cylinder was laid by Mr Gladstone on 16th August 1887. The Dee ends in the Irish Sea, in a tidal estuary 13 miles long and 3 to 6 broad, and forming at high-water a noble arm of the sea; but at low-water a dreary waste of sand and ooze (Kingsley's 'sands of Dee'), with the river flowing through it in a narrow stream. Its whole course is 90 miles long, and its chief tributaries are the Treveryn, Alwen, Ceirog, Clyweddog, and Alyn. Canals connect the Dee with the rivers of central England. The

ancient Britons held its waters sacred; Milton speaks of its 'wizard stream,' and Spenser of the

Dee, which Britons long ygone  
Did call divine, that doth by Chester tend.

**Dee**, a beautiful river of Aberdeen and Kincairdine shires, rising at an altitude of 4060 feet among the Cairngorm Mountains, and running 87 miles eastward, till it enters the German Ocean at Aberdeen, where in 1870-72 a mile of its channel was diverted for harbour improvements. It makes a descent of 2084 feet during the first 2½ miles of its course; at the Linn of Dee, 18 miles lower down, tumbles through a chasm 300 yards long, and at one point scarcely 4 feet wide; thereafter flows by Castleton of Braemar, Balmoral Castle, and Ballater; since 1864 has supplied Aberdeen with water; and is still a good salmon river, though not what it once was.—The *Kirkcudbrightshire Dee* issues from Loch Dee (750 feet above sea-level), and flows 38 miles south-eastward and southward, past Threave Castle and Kirkcudbright, to Kirkcudbright Bay. Midway it is joined by the Water of Ken, 28 miles long, a stream of greater volume than its own. It, too, affords fine fishing.

**Dee**, DR JOHN, alchemist, was born in London, 13th July 1527, and educated there and at Chelmsford, till in 1542 he was sent to St John's College, Cambridge, where for three years he studied eighteen hours a day. One of the original fellows of Trinity (1546), he earned the reputation of a sorcerer by his mechanical beetle in a representation of Aristophanes' *Peace*, and next year he fetched from the Low Countries sundry astronomical instruments. This was the first of many foreign visits—to Louvain and Paris (1548-51), where he lectured on Euclid, to Venice and Presburg in Hungary (1563), to Lorraine (1571), to Frankfort-on-Oder (1578), to Bohemia (1583-89), and even, it is said, to St Helena. He was imprisoned under Queen Mary on suspicion of compassing her death by magic (1555); but Edward VI. had conferred two church livings on him, and Elizabeth showed him considerable favour, twice visiting him at his Mortlake home, and in 1595 making him warden of Manchester College. He was constantly in difficulties, though he claimed to have found in the ruins of Glastonbury a quantity of the Elixir, one grain of which transmuted into gold a piece of a warming-pan. Indeed, he appears to have been as much dupe as deceiver, the dupe of his own assistant, Edward Kelley, during 1582-88. This knave, who had lost both ears in the pillory, professed to confer with angels by means of Dee's magic crystal (see CRYSTALLOMANCY), and talked him into consenting to a community of wives. In 1604 Dee petitioned to James I. to let him clear himself by public trial of the slander that he was a 'caller of divels,' but half a year later he was back at his invocations. He died wretchedly poor, in December 1608, and was buried in Mortlake church. 'A mighty good man he was,' by Aubrey's showing, 'a great peace-maker, a very handsome man, with fair, clear, sanguine complexion, and a long beard as white as milke.' His eldest son, Arthur (1579-1651), was likewise an alchemist, a friend of Sir Thomas Browne. Of Dr Dee's seventy-nine works, only thirteen have ever been printed: the rest are in MS. at Oxford, Cambridge, and the British Museum. They deal with logic, mathematics, astrology, alchemy, navigation, geography, and the reformation of the calendar (1583), in which at least he was much in advance of his countrymen. See his *Private Diary* (ed. Halliwell-Phillipps, Camden Society, 1842), Cooper's *Athenæ Cantabrigienses* (vol. ii. 1861), his *Life* by Miss C. Fell Smith (1909), and a monograph by G. M. Hort (1922).

**Deed**, EXECUTION OF, the performance of the ceremonies required by law in order to make a deed binding and effectual. These ceremonies in England consist in signing, sealing, and delivering. Signing is usual in practice, but it is open to doubt whether it is strictly necessary in law. When a party, from any cause, is unable to write, it is usual for him to place his mark in the place of signature. But a mark is unnecessary, and signature by another, at request of the party, is enough. Sealing is the most ancient form of authentication of deeds, and comes from the Norman usage. A seal is absolutely essential to the validity of an English deed, but any species of seal is sufficient, and in practice a common wafer is usually affixed. Delivery is the third requisite. Delivery may be made either to the grantee or to another person for him. In the former case, the deed becomes absolute; in the latter, it is called an *Escrow*, and does not yet acquire its full effect. Witnesses are not absolutely required to a deed in England, but in practice it is usual that one witness should attest. Before execution, a deed must be read, if required, by a party to it; and if not read, it is void as to the party requesting. A will (except that of a soldier or sailor in active service) must be in writing, and signed by the testator or by some other person in his presence and by his direction; and two witnesses must attest the signature.

In Scotland, sealing was once essential, but has long fallen into disuse. A deed is now probative on the face of it (i.e. is received as the authentic act of its grantor) if it is signed by the grantor on each sheet, and attested by two witnesses who are either designated in the deed itself, or in a designation added to their subscriptions before the deed is recorded or founded on in court. In case the maker of the deed cannot write, the deed is validly executed by one notary public or justice of the peace signing it for him in his presence and by his authority, and reading it over to him, all in the presence of two witnesses. A parish minister may act in his own parish as notary for signing a will. Holograph deeds—i.e. deeds written throughout in the handwriting of the grantor, are exempted from the rules as to execution; as also, out of favour to trade, are mercantile writings, such as Bills of Exchange.

In the United States, the formalities required for the transfer of real estate are governed by local laws. Generally throughout the states, signing, sealing, attestation, acknowledgment, and delivery are the essential requisites of a valid deed of conveyance. The usual form of attestation being 'signed, sealed, acknowledged, and delivered in the presence of us witnesses,' then follow the names of the subscribing witnesses. The grantor must himself sign the deed, or if it is signed by his agent he must adopt the signature as his own in the presence of the subscribing witnesses and the commissioner or other qualified officer. In the United States, a 'deed,' technically speaking, is an instrument under seal; hence a seal, although a mere formality, is essential, except in those states in which seals have been abolished by statute—Alabama, Louisiana, Texas, Virginia, Kentucky, Kansas, and Iowa. Neither wax nor wafer is necessary for a seal, although a wafer is generally used. A scroll with a pen inclosing the letters 'L.S.' is a seal within the meaning of the law, if it is the intention of the party appending it to adopt it as his seal, and by its use a specialty is created, the same as by the use of wax or wafer. It is not necessary to refer to the fact of sealing in the attestation clause. The number of witnesses required is governed by statutes in most of the states. Generally two are required, but in some of the states only one witness is necessary if the grantor

can read; and it is believed that in any state a deed otherwise properly executed with but one subscribing witness would be good as between the parties themselves. It has also been held that independent of any statute, a deed signed, sealed, and delivered, without being acknowledged or recorded, is valid as between the parties and their privies, but the provisions of a local statute as to the execution of a deed must be strictly followed, or the deed is inoperative. Delivery, although essential to the execution of a deed, need not be formally made in the presence of witnesses, but may be a matter of circumstance. A deed takes effect from the date of actual delivery, or the date of record. Everywhere in the United States it is the law that deeds of conveyance must be recorded either in the proper office of the county in which the land lies—or if the conveyance be by grant or letters patent from the state or United States, the record must be made in the land office of the state or United States. The recording of a deed has the force of *seisin* and possession under the English law. Deeds of conveyance of lands sold at judicial sale, or for taxes for several successive years and unredeemed made by the sheriff of the county, and deeds made in pursuance of a decree of court by the officer appointed for that purpose, are as effectual as if made by the grantor and his heirs, and must be executed with the same formalities and recorded within fifteen days; neither is it necessary to set forth in the deed as a part of the title the proceedings which culminate in the decree of sale. Federal decisions as to the formalities necessary to the execution of a deed are apparently conflicting. This arises from the application of the principle that land or property must be governed by the law of the place in which it is situated, and the lack of uniformity of State laws upon this subject. The United States laws are applicable only to lands belonging to the United States and those located within the territories. See also CONVEYANCING, CONTRACT, CHARTER, TITLE-DEEDS, WILL, ERASURE, REGISTRATION, &c.

**Deemster** is the title of the two chief judges in the Isle of Man (q.v.). In Scotland, *Dempster* or *Doomster* was the name of an officer formerly attached to the High Court of Justiciary, who pronounced the doom or sentence on condemned persons. The office was held along with that of executioner. See Scott's notes to *Old Mortality* and *Heart of Midlothian*.

**Deep-sea Exploration.** See CHALLENGER EXPEDITION, SEA, and SOUNDING.

**Deer**, formerly a beast in general (O.E. *déor*, not akin to Gk. *thēr*), as in the romance of *Bevis of Hampton*: 'Ratons and myse and soche smale dere, That was hys mete that vii yere'; now confined to the *Cervidæ*, a large family in the ruminant section of even-toed Ungulates. Though doubtless of common ancestry, the antlered ruminants or deer are definitely, though not very readily, separated from the other great family of horned ruminants or cattle. The contrasting characters of *Cervidæ* and *Bovidæ* are noted under the title ARTIODACTYLA (q.v.); only the chief peculiarities of the *Cervidæ* need here be noted.

**General Characters.**—If appendages are present on the head, they are true bony outgrowths, familiarly known as antlers. Except in one genus, they are confined to the males. There are two openings to the duct of the lachrymal gland, situated on or inside the orbit. A large cavity in front of the orbit cuts off the lachrymal from its usual contact with the nasal. The first molar tooth is short-crowned. There are usually upper canine teeth in

both sexes, and these are often large in the males. In addition to the functional third and fourth digits, the second and fifth are very generally represented. The placenta has few cotyledons or villous patches. Except in Australia and Africa, the Cervidae are distributed over the globe, usually living in pairs or herds in wooded and grassy regions, and feeding upon herbage. About 100 living and extinct species are known.

**Genera.**—Dr J. E. Gray classified the Cervidae into two groups, according to the position of a hair-tuft on the lower part of the hind-leg. Professor Garrod has divided them according to features in the skull; Sir V. Brooke has classified them according to the state of the limbs. In their general outlines the three classifications agree; that of Brooke is here followed.

A. Upper ends of the second and fifth metacarpals remain—Plesiometacarpi—e.g. *Cervus*. B. Lower ends of the metacarpals remain—Telemetacarpi; within which the three genera *Alces*, *Hydropotes*, and *Capreolus* are separated by other characters from a more definite section, including *Cariacus*, *Pudua*, and *Rangifer*.

**Important Forms.**—As many of the important deer will be separately discussed under their common names, a list of the distinctive types is all that is here necessary. A. *Cervulus muntjac*, from British India and the Malayan region, with large canines in the males (see MUNTJAK); *Elaphodus*, with very small unbranched antlers; *Rusa*, a sub-genus of *Cervus*, from the Indian region, including some of the largest and smallest species—e.g. *C. aristotelis*, *C. equinus*; *Rucervus*, another Indian sub-genus, with forms of small stature—e.g. *C. schomburgkii*; *Elaphurus*, *Axis* (q.v.); *Pseudaxis*, other sub-genera of *Cervus*; the genus *Cervus*, in the restricted sense, large deer in Palaearctic and Nearctic regions, including the Red Deer (q.v.), or *Cervus elaphus*, in Britain, Continental Europe, Algeria, Asia Minor, and the Caucasus, and *C. canadensis*, in North America; *Dama*, another sub-genus, including forms of medium size, from south-western Palaearctic regions—e.g. the Fallow-deer (q.v.), semi-domesticated in European parks. B. (1) The northern genus *Alces*, including the Elk (q.v.), of large size, with great antlers; the Water-deer (q.v.), or *Hydropotes*, without antlers in either sex; the genus *Capreolus*, including the small Roe-deer (see ROE) (*Capreolus caprea*), in Britain, Europe, North Palestine, &c. (2) The genus *Cariacus*, in its strict usage, including the Virginian Deer of the United States (*C. virginianus*) and the Mexican Deer (*C. Mexicanus*); the sub-genera of *Cariacus*—*Blastocercus*, *Furcifer*, *Coassus*, from South America; *Pudua*, from the Chilean Andes; and the Reindeer (q.v.), or *Rangifer*, with antlers in both sexes.

**Antlers.**—Antlers are usually present in the male deer, though absent in both sexes in *Hydropotes*, and present in both in the reindeer. Their nature as true bony outgrowths, their early covering with sensitive vascular skin or velvet, the drying of this to leave the horn a hard and insensitive weapon, the basal constriction and detachment, and the regrowth in the following year with an additional tine (No. 4 in the cut representing the fifth year), have been referred to at ANTLERS (q.v.). Amongst the technical terms are the permanent 'pedicle' or stalk from which the regrowth starts, the main stem or 'beam,' the branches, 'tines,' or 'snags,' and the not infrequently flattened or 'palmate' form. Antlers are of special importance as weapons used by the males in fighting for the possession of the females, and have doubtless been perfected by Sexual Selection (q.v.). They are also of interest in the parallel they illustrate between the life-history of the individual and the evolution of the race. The figure

given of antlers at successive years in a stag's life will also suit for the evolution of antlers in successive historic periods. Young deer develop in the first year small simple antlers, and the branches are added on the annual regrowths. So the earliest (Lower Miocene) deer had no antlers, the Middle Miocene species had simple, at most two-branched processes, as in the second year of life, while in the Upper Miocene three branches occur; and in Pliocene and Pleistocene the modern luxuriance

gradually appears. Sir V. Brooke gives full details (1) of the gradual evolution of antlers from very simple to complex forms, tracing the history from the earliest *Dremotherium* onwards; (2) of their constant tendency to vary, as is well known in the semi-domesticated species; (3) of 'variation extending far enough to induce the partial atrophy of one part of the antler to compensate for the extra development of some other part'; (4) of the transmission and establishing of such variations by heredity. A great part of the theory of evolution can be beautifully read from antlers alone.

The flesh, skin, and antlers of deer are valuable, but deer injure crops, eat the leaves, twigs, and bark of trees, and damage forest trees by rubbing their antlers against the trunks and branches.

See articles on the various kinds of Deer (RED DEER, &c.), DEER FORESTS, GAME LAWS, POACHING, STAG-HOUND; J. G. Millais, *British Deer and their Horns* (1897); Roosevelt, *The Deer Family* (1902).

**Deer.** OLD, a village of Buchan, Aberdeenshire, 36 miles N. of Aberdeen. Here, about 580 A.D., St Columba (q.v.) and Drostan, his nephew, established a monastery, which William Comyn, Earl of Buchan, refounded about 1219 for Cistercian monks. Little remains of the monastic buildings; but in 1715 a Latin MS., a small octavo of 86 pages, which had belonged to the monks of Deer, found its way to the Cambridge University Library, though not until 1857 was it discovered by Henry Bradshaw, afterwards university librarian. It contains the Gospel of St John, and parts of the other three gospels (mainly in the Vulgate version of St Jerome), the Apostles' Creed, and a fragment of an office for the visitation of the sick, with a Gaelic colophon, apparently of the 9th century. On the blank leaves and margins of the MS., in handwriting of the 11th or early 12th century, are several Gaelic entries relating to the endowments of the Columban monastery. These notes are of the highest interest as the oldest specimens of Scottish Gaelic; and only less interesting is the Gaelic ornamentation enriching the MS. See Dr John Stuart's edition of the *Book of Deer* (Spalding Club, 1869); Magnus MacLean, *Literature of the Celts* (1902); Sir A. Lawrie, *Early Scottish Charters* (1905).

**Deer-forests**, tracts of country devoted to the red deer or fallow deer, either for sporting or for breeding purposes. The requisites of a Scottish deer-forest are a great extent of quiet ground, high mountain tops and corries, plenty of moorland and pasture. There is now little wood in

Scottish deer-forests, and almost all other game, and cattle and sheep, must be excluded. One-tenth of the heather in a deer-forest should be burned every year, the heather living ten or twelve years; and in each forest a sanctuary should be provided. The forest of Mar is 80,000 acres in extent; Blackmount, 70,300; Reay, 64,600; the rest are smaller, some as low as 10,000 acres. The requisites of an English deer-park, on the other hand, are wood, lawn, with sufficient underwood, rough grass, and bracken, in an inclosed and undulating country of rich soil. In Scotland, deer-stalking largely increased during the 19th century; in 1812 there were only five forests; a hundred years later some 130, with a total area of nearly 3,600,000 acres. Since 1912 the area has diminished. In England, since 1750, when fox-hunting superseded deer-hunting, deer are kept chiefly for breeding and ornament, being sometimes fed in stalls. There are, however, several packs of staghounds which hunt the red deer—e.g. in the high ground of Somerset and Devon. Originally, in both England and Scotland, the king's nobles and the church held special forest jurisdictions of the most oppressive kind. Thus, in Scotland, the forester might forfeit cattle and other goods found within the forest. In England, the Norman lawyers pretended that all game belonged to the king. King John had 18 forests, 13 chases, 781 parks. A chase was an open forest, not subject to special forest law; a park was an inclosed chase on the land of the owner; a *purlieu* was an addition made to an old forest. The *Charta de Foresta* disafforested large tracts of land, and prevented the arbitrary creation of forests. In the Highlands of Scotland it was sheep-farming—not in the first instance afforestation for sport—that drove out the crofters, and the decay of sheep-farming facilitated the extension of forests. With new economic conditions since the Great War, the tide turned towards sheep-farming again. See the Report of the Committee on Deer-forests in Scotland (1922), and a book by A. I. McConnochie (1923).

**Deerhound.** See STAGHOUND.

**Deer Mouse** (*Hesperomys*), often called Vesper Mouse, a genus of American rodents representing in the New World the Old-World mice, from which they differ only in trivial characters. The white-footed or deer mouse (*H. leucopus*) is found over the greater part of North America in several varieties. It is about 3 inches in length, of variable but frequently fawn colour; sometimes arboreal, sometimes burrowing; feeding chiefly on corn and nuts, which it stores for winter. See MOUSE.

**Deer-stealing.** See GAME-LAWS, POACHING.

**Deés, Dés, or Dér,** a town of Transylvania, on the Szamos, 37 miles NNE. of Klausenburg by rail. Rock-salt is mined in the neighbourhood. Pop. 10,000.

**Defamation.** See LIBEL.

**Default.** A party to an action is in default when he fails to comply with the rules of procedure. If the defendant, for example, fails to appear to the writ, the plaintiff may have judgment against him; if the plaintiff fails to deliver a statement of claim, the defendant may apply to have the action dismissed. Judgment by default may be set aside, on such terms as to costs, &c. as the court thinks just. In Scotland, a decree by default may be recalled by reclaiming note, but after the time for reclaiming has expired, an action of reduction must be brought to set it aside.

**Defeasance, DEED OF,** in English law, an instrument which defeats the force or operation of some other deed or estate. That which in the same deed is called a condition, in a separate deed is called a defeasance.

**Defectives (MENTAL).** See IDIOCY.

**Defender of the Faith,** a title conferred in 1521 on Henry VIII. by Pope Leo X. as a reward for writing his *Assertio septem Sacramentorum*, in answer to Luther. The title was afterwards confirmed by parliament (35 Henry VIII. chap. 3), and has ever since been used by the sovereigns of this country. The corresponding title in Spain is 'Most Catholic,' and in France was 'Most Christian King.'

**Defenders,** a Catholic association in Ireland (1784-98), the opponents of the Peep o' Day Boys.

**Deffand, MARIE DE VICHY-CHAMROND, MARQUISE DU,** one of the most brilliant letter-writers of the 18th century, was a member of a noble Burgundian house, and was born in 1697. She was educated in a convent in Paris, and as a girl became famous for her wit, audacity, and beauty. In 1718 she married the Marquis du Deffand, from whom she shortly afterwards separated. She led a life of gallantry for a number of years, and became a conspicuous figure in the literary society of Paris, her salon in the Rue Saint Dominique being a favourite resort of the *philosophes*. She was a correspondent of Voltaire, Montesquieu, D'Alembert, and other great men of letters of her day. In 1753 she became blind, and in the following year she invited Mademoiselle de Lespinasse to live with her and help her to preside over her salon. The arrangement lasted for ten years, when a quarrel broke out through Madame du Deffand's jealousy, and Mademoiselle de Lespinasse departed, taking away with her D'Alembert and others of the elder lady's former admirers. From 1766 Madame du Deffand carried on an interesting correspondence with Horace Walpole, who held her in the highest estimation, and pressed the use of his purse on her when she fell into pecuniary troubles. 'To say nothing of her extraordinary parts,' Walpole wrote, 'she is certainly the most generous friendly being upon earth.' Really she was as selfish and spiteful as she was witty and shrewd. She died 24th September 1780.

See *Correspondance de Madame du Deffand* (new ed. 5 vols. 1865-67); her *Letters to Horace Walpole and Voltaire* (4 vols. Lond. 1810); *Asse, Malle. de Lespinasse et la Marquise du Deffand* (1877); *Lettres de la Marquise du Deffand à Horace Walpole*, with notes by Mrs Paget Toynbee (first complete edition, 3 vols. 1912).

**Defilading,** in Fortification (q.v.), consists in determining the direction and height of the rampart, so that the interior of the work may not be commanded by the fire of the enemy. To prevent the lines being enfiladed, their prolongations must avoid all places where hostile batteries could be posted, and the parapets must be of sufficient height to protect the interior from frontal fire.

**Definite Proportions, LAWS OF,** in Chemistry. See ATOMIC THEORY.

**Definition,** the process by which we determine the common qualities of the objects belonging to any given class, so as to distinguish effectively that class from other classes. Regarding the class as a species, we give the proximate genus and the difference; genus here denoting the distinctive qualities belonging to all of the genus, while the difference marks out the part of the genus in question. A good definition should state the essential attributes of the species defined, without containing the name itself, and should be exactly equal in denotation with it.

**Deflagration** is the term applied to the rapid combustion of ignited charcoal when a nitrate (such as potassium nitrate) or a chlorate (such as potassium chlorate) is thrown thereon. As chlorates do not occur naturally, it follows that deflagration with a natural salt indicates a nitrate; and if the deflagration be accompanied by a violet flame, it is

characteristic of potassium nitrate (ordinary nitre or saltpetre); and if by a strong yellow flame, it is indicative of sodium nitrate (cubical nitre).

**Deflection**, in Navigation, the departure of a ship from her true course; in Optics, a deviation of the rays of light toward the surface of an opaque body.

**Defluxion** (Lat. *defluxio*), a discharge from a mucous membrane, especially of the air-passages, as in catarrh.

**Defoe**, DANIEL, immortal as the author of *Robinson Crusoe*, was born in 1659 or 1660, in the parish of St Giles, Cripplegate, London. His family belonged originally to Northamptonshire, and his father, James Foe, became a butcher in St Giles's. It was Daniel who first changed his name to De Foe, or Defoe, about 1703, for unknown reasons. He had a good education at a dissenting academy, but soon abandoned his early idea of becoming a dissenting minister, and engaged in business, apparently as a hose-factor, about the year 1685. Little is known of his early life, but it seems that at some undetermined time he had travelled in France, Germany, Italy, and Spain, and that he was out with Monmouth, and it is certain that he volunteered into King William's army in 1688, and became bankrupt in 1692; his debts, or at least great part of them, he paid up later with a scrupulousness most honourable to him. He next became accountant to the glass-duty commissioners, and secretary to a Tilbury pantile factory. His *Essay upon Projects* appeared in 1697, and towards the close of William III.'s reign he became noted as an able and busy pamphleteer in support of the king's policy, against occasional conformity, and in other controversies. His vigorous poem, *The True-born Englishman, a Satyr* (1701), was an attempt to apologise for the king's being a Dutchman by proving the English themselves to be a most composite race. His restless pen was active throughout the bitter struggle under Anne between the High-Church party and the dissenters, and his famous treatise, *The Shortest Way with the Dissenters* (1702), made him a martyr in the cause. Ostensibly written by a 'high-flyer,' it advocated the extirpation of dissenters with a masterly irony (*pace* Mr Saintsbury), which at first deceived and then infuriated his opponents, as, in his own words in *The Present State of Parties* (1712), it 'cut the throat of the whole party.' The House of Commons ordered the book to be burned, and a reward of £50 was offered for his apprehension, from which fortunately we have an exact description of his appearance as 'a middle-sized, spare man, about forty years old, of a brown complexion, and dark brown-coloured hair, but wears a wig; a hooked nose, a sharp chin, gray eyes, and a large mole near his mouth.' Tried at the Old Bailey in July, he was sentenced to pay a fine of 200 marks, to stand thrice in the pillory, and to be imprisoned during the queen's pleasure. Accordingly, the 'unabashed Defoe' stood in the pillory the last three days of July 1703, in the midst of a sympathetic mob that protected him from insult, and even drank his health. On the same day he suffered appeared his masculine *Hymn to the Pillory*, which concluded with a noble defiance to the government, expressed in some of his finest lines. During his imprisonment in Newgate he continued an incessant literary activity, but (contrary to what used to be believed) he had been liberated (about 1st November 1703) at Harley's instance, before he published a 'true collection' of his writings, and started his *Review* (19th February 1704–11th June 1713), at first a weekly, after eight numbers a bi-weekly, and after the eighth number of the second volume a tri-weekly newspaper, 'purged from the errors and partiality of

newspapers and petty statesmen of all sides.' This was Defoe's largest, if not his most important work, and indeed forms one of the greatest monuments of literary industry ever reared by a single hand, embracing as it does in more than five thousand printed pages essays on almost every branch of human knowledge, and these written during but nine years, in which he was actively engaged as a political spy and intriguer in journeys all over England and Scotland, in which also, according to W. Lee, he published no fewer than eighty distinct works, themselves containing as many as 4727 pages. Its 'Scandal Club,' which discussed minor matters of manners, was distinctly the forerunner of the more famous *Tatlers* and *Spectators*.

Defoe's moral character, never very noble, seems now to have deteriorated. Harley procured him pecuniary relief and employment as a political agent. After a short stay at Bury St Edmunds he returned to London, maintaining at both places his activity in his *Review*, and in such admirable pamphlets as *Giving Alms no Charity*, and *Employing the Poor at a Grievance to the Nation* (1704), a masterly denunciation of indiscriminate charity and national workshops—a scheme propounded by Sir Humphrey Mackworth. Next year (1705) appeared *The Consolidator*; or *Memoirs of Sundry Transactions from the World in the Moon*, a political satire, which some have supposed may have supplied a hint for *Gulliver's Travels*; and the year after (5th July 1706) his masterpiece of circumstantial narrative, *The True Relation of the Apparition of one Mrs Veal*. Lee disproved the old story that this fiction was a mere *tour de force*, written to sell an unsaleable book, Drelincourt on *Fears of Death*, by showing that Drelincourt's book was already popular, being then rapidly running through its third English edition, while Defoe's pamphlet was only attached to its fourth edition by the author's consent. Mr Aitken showed that the story was current at the time. His next work was his *Jure Divino*, a tedious political satire, in twelve books of poor verse. In 1704 and 1705 Defoe was sent by Harley on secret missions to various parts of England, and in October of the next year we find him sent to Scotland as a secret agent to promote the Union, and there he lived till December 1707. His *History of the Union* appeared in 1709, and in the same year Sacheverell's famous sermon gave him the opportunity of a fling at an old enemy. At the beginning of 1708 Harley's fall had made his political position somewhat precarious, but he worked for Godolphin in Scotland, until the fall of the Whigs after the error of Sacheverell's impeachment and Harley's return to power (1710) left him under the necessity of arguing that Englishmen should support the country even under a Tory ministry. In the pages of his *Review* he did his best to preserve the semblance of consistency, but not all his cleverness could save him from the contemporary reproach of being a time-server and a renegade. It is itself significant that his journalism was always anonymous from his second employment by Harley. He played a difficult and dubious part in the strange intrigues that preceded the accession of the House of Hanover, with the result that at length he found himself in a general discredit, which his apology, entitled *An Appeal to Honour and Justice* (1715), did not remove. Letters of his found in the State Paper Office in 1864 revealed the fact that in 1718 he was in somewhat equivocal government service, subediting Jacobite and High-Church organs, as the *Mercurius Politicus*, Dormer's *News-Letter*, and *Mist's Journal*. In such a dexterous way that 'the sting should be entirely taken out, although it was granted that the style should continue Tory' (second letter). Further, in the same letter he describes his purpose

more fully, that these papers 'will be always kept (mistakes excepted) to pass as Tory Papers, and yet be disabled and enervated, so as to do no Mischief, or give any Offence to the Government.' He describes himself further as 'for this Service, posted among Papists, Jacobites, and enraged High Tories—a generation who, I profess, my very Soul Abhors. . . . Thus I bow in the House of Rimmon.' Defoe was not exactly scrupulous in his point of honour, but it is certain he never was a Tory, and it would not be difficult for him to construct an argument by which he could persuade himself that by this dangerous and ambiguous means he was doing good service to the cause of liberty and religion.

Although he wrote busily in the journals almost to the close of his life, henceforward his interest for us is mainly literary. In 1715 appeared the first volume of the *Family Instructor*, and four years later the first volume of the immortal *Robinson Crusoe*, which at once leaped into that popularity which it will never cease to retain. The same year appeared the second volume, and the year after the greatly inferior sequel. Defoe's realistic imagination worked most freely on a basis, however slight, of fact, and this was found for him in the four years' solitary residence of a marooned sailor, Alexander Selkirk, on the island of Juan Fernández. Perhaps no man at fifty-eight in the whole history of literature ever devised a more splendid masterpiece of creative imagination than this marvellous story, which carries with it the irresistible conviction of very truth. In 1720—his most prolific year—he gave to the world the *Life and Adventures of Duncan Campbell*; the famous *Memoirs of a Cavalier*, the most real and truthful of all our historical romances, which the great Chatham accepted as genuine history; and *Captain Singleton*, a book of such brilliancy, vigour, and interest as would alone have given a reputation to any other writer. His next great creative year was 1722, in which he issued *The Fortunes and Misfortunes of Moll Flanders*, which is at least a marvel of the novelistic art; *The Journal of the Plague Year*, called in the second edition *A History of the Plague*, a fresh masterpiece of verisimilitude and reality; and the *History of Colonel Jack*, which, though unequal throughout, and actually feeble towards its close, is in its commencement, and in episodes here and there, the most charming and, perhaps, the greatest of all his books. Later works were *Roxana, or the Fortunate Mistress* (1724), a weaker Moll Flanders; *A Tour through the Whole Island of Great Britain* (1724-26); *A New Voyage round the World* (1725); *The Complete English Tradesman* (1725-27), a glorification of mere money-getting, which Charles Lamb condemned for its 'vile and debasing tendency'; *The Political History of the Devil* (1726), which may be grouped with his *System of Magic* (1726) and *Essay on the Reality of Apparitions* (1727). The only other works that may here be mentioned are his *Religious Courtship* (1722), and *The Treatise concerning the Use and Abuse of the Marriage Bed* (1727), which reveal the strangely limited and vulgarly profit-and-loss character of his conception of religious duty. His *Everybody's Business is Nobody's Business* (1725) is an amusing diatribe upon the insolence of domestic servants—a subject to which he frequently recurs.

Meantime Defoe had been prospering in his affairs. He built himself 'a very handsome house' at Stoke-Newington, where he amused himself with gardening and the company of his three daughters. A mystery not yet satisfactorily explained hangs around some months in 1729-30. His affairs seem to have fallen into confusion, one of his sons had behaved undutifully, and he was under apprehen-

sions of some trouble, which may, however, have been due merely to a degree of mental derangement. After a recovery of literary activity and power, he died 'of a lethargy' in Ropemakers' Alley, Moorfields, 26th April 1731, and was buried in Bunhill Fields.

Defoe remains one of our greatest English writers, and his greatness is of a kind unlikely to be disturbed by a competitor. His immense vitality and energy, clear-sightedness, and ready power of forcing plain arguments either in prose or verse to an irresistible conclusion, make him the typical journalist—to be surpassed only by Swift at his best; but it is to a much rarer quality than this that he owes his fame—his incomparable realism and faithfulness in fiction, the secret of which must be looked for not in his singularly plain and direct language, his simple-looking but most effectively artistic digressions, or his perfect though artless preservation of dramatic propriety, but in that subtle and impalpable genius which informs his style. For his character he was shifty, casuistical, and double-dealing; but with all his political inconsistencies he remained true to the principles of the Revolution.

See the *Lives* by George Chalmers (1786), Walter Wilson (1830), Chadwick (1859), Lee (1869), Wright (1894), and Whittin (1900); the studies by Scott, Lamb, Hazlitt, Forster, Leslie Stephen, and Professor Minto; and the chapter in the *Cambridge English Literature* (vol. ix. 1912) by Professor W. P. Trent, who has undertaken a full life and bibliography. The best approximations to complete editions of Defoe's works have been those of Scott, Hazlitt, and Aitken (16 vols. 1895).

**Deforcement**, in English law, includes abatement, intrusion, disseisin, or any other wrong whereby he that has the right to a freehold is kept out of possession. 'Deforciant' was formerly the technical name of the defendant in the fictitious proceeding called a Fine. In Scotland, the term deforcement is most commonly used to denote forcible obstruction of the officers of the law: this is one of the cases in which the Court of Session has a criminal jurisdiction.

**Deformities** are variations in the form of the body as a whole, or in one or more of its parts, constituting a departure from the normal conditions of structure, and usually implying a corresponding divergence from natural and healthy functions. They may be divided into three groups, with reference to their origin—the *hereditary*, the *congenital*, and the *acquired*. The first group is characterised by a marked tendency to recurrence in the line of direct descent from generation to generation, as in those cases where the presence of extra fingers or toes has become characteristic of many members of one family (for a full record of an interesting case in point, see Carpenter's *Human Physiology*). Such hereditary tendencies to modification of form along certain lines of descent constitute local examples of the 'Natural Law of Variation,' which plays an important part in the Darwinian theory of the origin of species. According to this theory, modifications which are of value in the exigencies of the struggle for existence will become perpetuated, and supersede earlier and less favourable conditions of conformation; while modifications that do not possess such value, after repetition through one or two generations, disappear again, and these, since they are useless as well as aberrant conditions, are properly included within the group of *hereditary* deformities. In the second group, that of *congenital* deformities, occur those much more frequent abnormalities that result from disturbing influences acting on the otherwise normal embryo previous to its birth. These anomalies occur chiefly as deformities by defective development, and deformities by perverted development.

Arrested development may be general, affecting the whole body, when a dwarf is produced; or local, affecting individual organs or parts, producing a great variety of obvious local deformities, in disproportion or malformation of special regions of the body. If the local arrest of development is absolute, the defect caused by it is so great as to constitute a Monstrosity (q.v.), where whole organs may be absent, as the brain (*anencephalia*), the skull (*acrania*), the lower jaw (*agnathia*), all the limbs (*amelus*), or one or more of them, as one arm, one eye (*monobrachius*, *monopus*). Perverted development is seen in cases where parts normally separate become fused together, as in the 'siren-monster,' in which both lower limbs are welded into one tapering extremity (*mermaid*). The causes producing these monstrosities and the lesser and more common deformities of the same class are very varied. Modern writers have, however, made them a subject of special study under the name Teratology (*teras*, 'monster,' *logos*, 'science'), and have devised experimental conditions which illustrate the subject. Thus, in the case of the embryo chick, Panum found that deformities could be produced by varying the temperature of the hatching apparatus, and varnishing the egg shells; while Dareste discovered that a like result occurs if the eggs be placed vertically instead of lying on their sides; and Gerlach, by varnishing the whole surface of the egg with the exception of a Y-shaped streak on one side, succeeded in producing a double-bodied chicken.

In the human subject the cause of the deformity may depend on purely mechanical conditions, as when the navel-string of the embryo becomes twisted round a limb and causes its gradual separation and destruction (so-called 'intra-uterine amputation'). In many cases, however, the cause is much more recondite, and appears to depend upon a variety of circumstances affecting the maternal organisation. In an increasing proportion of cases which are carefully investigated, it appears that maternal impressions, the result of shock or unpleasant experiences, may have a considerable influence in producing deformities in the offspring. This has for long been a popular theory, and it is one that recent scientific observation is tending to confirm, but only in a comparatively limited proportion of cases; and it must be admitted that the majority of cases cannot be explained on any theory of causation as yet suggested.

The chief varieties of malformation, coming under the heading of *congenital* deformities, are the following: (1) As regards the *number* of parts. In the *Siren*, two lower extremities are fused into one mass, but dissection shows that all the constituent bones of the limbs may be present, though much distorted, in the combined structure. In the *Cyclops*, the eyes are similarly fused into one irregular structure occupying the centre of the face. (2) As regards the *size* of parts. This may involve the whole body, as in dwarfs, of whom there have been some remarkable peripatetic specimens: the Corsican fairy was only 2 feet 7½ inches high; Mademoiselle Crachami, the smallest lady who ever lived, died at ten years of age, only 20 inches in height. This kind of deformity is not necessarily hereditary; the father of Borowlaski, who was only 39 inches when thirty years old, had six children alternately short and tall; and dwarf women have brought forth infants as long, when extended, as their mothers. One limb only may be diminutive. Of course, deformities the opposite of these exist, such as giants, or instances of premature or excessive local growth. O'Byrne, the Irish giant, measured 8 feet 4 inches when he died at the age of twenty-two. Such individuals are generally subject to premature decay. One finger

or one toe often grows to such abnormal dimensions as to necessitate its removal (local hypertrophy). (3) As regards the *shape* and *continuity* of parts. Distortion may occur from partial paralysis or irregular muscular action at an early stage of development, giving rise to Club-foot (q.v.), club-hand, &c.; or natural fissures or apertures which should close in the course of development may remain open, as in hare-lip, cleft palate, and *spina bifida* (non-union of spinal bones).

*Acquired deformities* arise in various ways as the result of injury or disease at any period after birth. Among injuries, burns, scalds, fractures, and dislocations are the most fertile causes of permanent deformity; and among diseases, rickets, and other diseases of bone, leprosy, and rheumatic affections are common causes. Another group of these affections, known as 'trade' deformities, are directly traceable to the special work done by the person suffering from them.

**Defregger**, FRANZ VON, Austrian historical and genre painter, was born 30th April 1835, a peasant's son, at Stronach, near Dölsach, in the Pusterthal. Inheriting and selling his father's farm, he went to Innsbruck to study sculpture with Stolz, by whose advice he soon removed to Munich, and studied painting with Dyk and Anshütz. After a short sojourn in Paris he returned to Munich in 1866, and became a pupil of Piloty. There he continued to live, himself a professor in the Akademie from 1878. Innocent and amiable by nature, he painted subjects from Tyrolean history and Tyrolean peasant life, which won great popularity by their freshness and truth, not quite free from sentimentality. He died at Munich, 1st January 1921.

**Degas**, EDGAR HILAIRE GERMAIN, a great French painter, was born in Paris, 19th July 1834, a prosperous banker's son, and was educated at the Lycée Louis-le-Grand. Deserting law for art, he entered the Ecole des Beaux-Arts, and became a pupil of Lamotte in 1855. The deepest and most enduring influence upon him, however, was that of Ingres, who was never formally his teacher. As for Ingres, draughtsmanship was for Degas the thing that mattered most in a picture. He visited Rome in 1856. On returning to Paris he painted historical subjects for a time; but essentially a realist, he passed through portrait-painting to truthful observation of contemporary Parisian life, especially of the racecourse and the ballet, for the sake of the opportunity that these subjects, often paltry and sordid in themselves, give for the treatment of line in movement. In 1870 Degas withdrew from the Salon, but he often exhibited from 1874 with the Impressionists, with whom he had much in common, though he is apart from them in the matter of colour. Japanese influence is strong in him. 'Le Ballet de Robert le Diable' (National Gallery) shows his breach with tradition in composition. He worked chiefly in pastel. He died at Paris, 27th September 1917. See Life by Henri Hertz (1920), and a study by Meier-Graefe (1923).

**Degeneration**, a biological term used to describe those not unfrequent cases where an entire organism falls below the structural level of its young stages, or where an organ in the same way loses its fullness of function, and becomes more or less atrophied, abortive, and simplified. Thus many parasitic worms, crustaceans, &c. are emphatically simpler than their free-swimming larvæ, and the sessile adult Ascidian shows only traces of the vertebrate characters which are plain enough in the active young. Thus, too, a crustacean which starts with a well-developed eye, may exhibit the gradual loss of this on assuming a dark habitat. The term is best confined to cases

where a level of structure exhibited during early life is more or less lost in the adult. Degeneration must be distinguished (a) from occasional *abortion*, (b) from *Reversion* (q.v.) to an ancestral type, and (c) from the occurrence of *rudimentary and undeveloped organs* where a character possessed by ancestral types remains more or less undeveloped, or shows itself only in embryonic life. Degeneration may be due to the environment, or to cessation of function, or to some more subtle constitutional cause. Absence of food, heat, light, &c. may mean the absence of the necessary stimulus for the growth and maintenance of the organs, or superfluity of food may cause one system to preponderate over others. Nor can it be doubted that cessation of function checks the food-supply to a given organ, and in other ways helps to bring about its degeneration. But, on the other hand, some less obvious cause—the fatigue of early life, a constitutional sluggishness, &c.—may share in conditioning degeneration, as in the case of the majority of the Tunicata. Weismann and others, however, would explain degeneration by the non-operation of natural selection. On this view, organs are not only developed but maintained by natural selection, and if it happen that an organ is no longer an advantage in this struggle for existence (e.g. eyes in dark caves), then natural selection no longer maintains that organ, and it disappears in the course of generations.

See, for instances, ASCIDIANS, CAVE-ANIMALS, CRUSTACEA, INSECTS, PARASITIC ANIMALS, PARASITIC PLANTS; also ENVIRONMENT, EVOLUTION, &c.

**De Gérando, JOSEPH MARIE, BARON**, was born 29th February 1772, at Lyons, of Italian blood. Fleeing from Paris to Germany, he entered (1797) Masséna's army as a private, and wrote a treatise, 'crowned' by the Academy, *Des Signes et de l'Art de Penser* (1800). In 1802 appeared his *De la Génération des Connaissances Humaines*, a precursor of his *Histoire de Philosophie* (1803), long reputed the best French work on the subject. It procured him, in the following year, admission into the Academy. He was appointed secretary-general to the Ministry of the Interior by Napoleon. But De Gérando is better known by his philanthropic writings. His excellent work, *Le Visiteur du Pauvre* (1820), obtained the Montyon prize, as did also his *Du Perfectionnement Moral* (1824). De Gérando was elevated to the peerage in 1837, and died 12th November 1842, vice-president of the Council of State.

**Deggendorf**, a town of Lower Bavaria, on the Danube, which is here crossed by two bridges, 39 miles NW. of Passau by rail, with manufactures of paper, linen, woollens, stoneware, and matches. Its church of the Holy Sepulchre is often visited by more than 30,000 pilgrims in a year. Pop. 7000.

**Degraded**, in Heraldry, means placed upon steps or *degrees*.

**Degree**. See CIRCLE, GRADUATION, THERMOMETER, LATITUDE AND LONGITUDE. Were the earth perfectly spherical in shape, the distance between two points on the same meridian differing by one degree in latitude would be exactly equal to  $\frac{1}{360}$  of the whole meridian, and would be the same at all parts of the earth's surface. But owing to its oblately spheroidal shape the distance increases from the equator, where the curvature is greater, to the poles, where it is less. At the equator the length of a degree of latitude is 362746·4 feet; while at the poles it is 366479·8 feet. The differences between the length of the degree of latitude in different latitudes, ascertained by actual measurement, is one of the proofs that the figure

of the earth is not that of a sphere, but that of an oblate ellipsoid.

A degree of *longitude* is the length between two meridians that make an angle of one degree at the poles, measured by the arc of a circle parallel to the equator passing between them. It is clear that this space is greatest at the equator, and vanishes at the poles; and it can be shown that it varies with the cosine of the angle of latitude. The annexed table shows the lengths of a degree of longitude for places at every degree of latitude from 0° to 90°. It is computed on the supposition that the earth is a sphere.

**Degrees, UNIVERSITY.** In its original signification a degree was simply a certificate that the person who held it was qualified to take part in the public teaching of a university. In the fully developed medieval university there were the four faculties of arts, law, medicine, and theology; and in each of these faculties there were special degrees of its own. These degrees were the baccalaureate, the licentiate, and the doctorate, though, strictly speaking, the first was not a degree, since it did not confer the right of public teaching. For the attainment of each degree certain subjects were prescribed for examination, as also a fixed term of study in connection with some university. Both the subjects and the periods of study varied with the progress of learning; but the different universities always sought to preserve a common standard. In Paris, at the close of the 15th century, the terms of study requisite to qualify for teaching in the different faculties were the following: in arts, four years; in law, seven; in medicine, eight; and in theology, fourteen. In modern times a degree in arts is simply a certificate of a certain measure of acquaintance with the subject to which it refers; but in the case of the higher faculties, that is, of law, medicine, and theology, the degree also implies a license to exercise the functions of the professions that depend on these faculties. It was formerly an indispensable condition to obtain a degree that the knowledge it represented should have been acquired at one or other of the legally constituted universities; but of late years certain universities, such as that of London, have been founded, which grant degrees to persons who pass examinations on prescribed subjects without the necessity of university attendance. A still further departure from the

original import of the term is seen in what are known as 'honorary degrees.' Such degrees are conferred by universities on persons who have distinguished themselves in spheres of life which have no direct connection with the studies for which they exist. Thus, eminent soldiers, artists, and even merchants, have received the degree of Doctor of Laws. Not a few scholastic bodies are even understood to grant degrees on purchase, or on other such easy conditions that the original significance of the degree is completely lost. In the middle ages the right to confer degrees was granted by the pope, who was the recognised head of all the universities; and at the present day he claims the privilege of directly conferring degrees on whom he pleases. In Protestant countries the right can be granted only by the state. By an act of the reign of Henry VIII., the Archbishop of Canterbury received the right of conferring degrees; but these, known as 'Lambeth degrees,' never carried with them the same privileges as those of Oxford and Cambridge. In the medieval universities, music made part of the curriculum of the faculty of arts, and doctors and bachelors of music are still created by some universities. The German doctorate in philosophy corresponds in some respects to the M.A. degree elsewhere. Degrees in science are of comparatively recent institution. See ABBREVIATIONS, UNIVERSITY, DOCTOR.

**De Gubernatis.** See GUBERNATIS.

**Dehiscence** (Lat., 'gaping'), a technical term applied to the mode of opening of certain ripe fruits; see FRUIT.

**Dehmel, RICHARD**, German poet, was born, a forester's son, at Wendisch-Hermsdorf, in Brandenburg, 18th November 1863. He studied at Berlin and elsewhere, and became secretary to an insurance company. At this period, besides writings on insurance, he published two collections of poems, *Erlösungen* (1891) and *Aber die Liebe* (1893), and a book of short stories, *Lebensblätter* (1895). Thereafter he confined himself to literature, living first at Pankow, near Berlin, afterwards at Blankenese. His plays are *Der Mitmensch* (a tragicomedy, 1895), *Lucifer* (a pantomime play, 1899), *Fitzebutze* (a dream play, 1907), *Michel Michael* (an allegory for the German people, 1911), and *Die Menschenfreunde* (1918). Besides some books for children, his other works are *Weib und Welt* (poems, 1896); *Zwei Menschen* (a novel in ballads, 1903), perhaps his best work; *Die Verwandlungen der Venus* (1907), *Die Gottesnacht* (1911), *Blinde Liebe* (1912), narrative poems; *Betrachtungen über Gott, Kunst und die Welt* (1908); *Die Schöne Wilde Welt* (poems, 1913); *Volksstimme Gottes* (war poems, 1914); and *Zwischen Volk und Menschheit* (a war diary, 1919). Though an epileptic, he volunteered for war service, which led to his death, 8th February 1920. Dehmel was probably the greatest German poet of his time. Of vigorous personality and vehement lyrical inspiration, intellectually and ethically sound and robust, he has been classed, for his strength, with Nietzsche; but he was too strong to be a mere Nietzschean. See *Mein Leben* (1922), and *Ausgewählte Briefe* (1922).

**Dehra**, the capital of the Dehra Dún district in the United Provinces of India, is pleasantly situated in a mountain-valley, 2300 feet above sea-level, and 100 miles NE. of Meerut. The forestry school (1878-1914) is the finest building in the town, and contains magnificent collections. The Royal Indian Military College was opened in 1923. Pop. (with cantonment) 38,000.

**Deianeira**, daughter of Eneus and Æthea, and sister of Meleager. She became the wife of Herakles, but unwittingly caused his death by

sending him the mantle of the centaur Nessus, which was said to have the property of preserving love, but was really steeped in fatal poison. The poison entering his frame, the hero suffered such agony that he ordered a funeral pyre to be erected in Mount Æta, and cast himself into the flames, whereupon Deianeira hanged herself from grief.

**Dei Gratia** (Lat., 'by the grace of God') is a formula taken from several apostolical expressions in the New Testament. It is believed to have been first formally used by the bishops at the Council of Ephesus, 431 A.D. Afterwards, it came to be appended by archbishops, bishops, abbots, monks, and even chaplains, to their titles, in letters, and other documents, as a humble expression of dependence on the Most High. After the middle of the 13th century, the higher clergy wrote *Dei et Apostolicæ sedis gratia*, 'by the favour of God and the apostolic see.' In the British Islands, this style was generally dropped about the time of the Reformation, but it was occasionally given to the Archbishops of Canterbury and York, even after the beginning of the 17th century. Many temporal princes, earls, and barons made use of the formula *Dei Gratia*; William II. and Edward III. of England employed it; and before the 15th century, no idea of independence or of divine right seems to have been attached to it. But in 1442 King Charles VII. of France forbade its use by the Comte d'Armagnac, and in 1449 obliged the Duke of Burgundy to declare that he used it without prejudice to the rights of the French crown. These instances show that it had now begun to be regarded as belonging exclusively to sovereigns who owed no allegiance to any other earthly potentate or power. In this way, what was originally a pious expression of humility came to be looked upon as an assertion of the doctrine of the 'divine right' of kings.

**Deinotherium.** See DINOTHERIUM.

**Deipnosophists.** See ATHENEUS.

**Deira**, an ancient Anglian kingdom, extending from the Tees to the Humber, and westwards to the borders of Cumbria. With its northern neighbour, Bernicia, it was afterwards merged in the kingdom of Northumbria, but later both were earldoms under the West Saxon kings.

**Deir-el-kamar** ('convent of the moon'), a town of Syria, formerly the capital of the Druses, 13 miles SSE. of Beirut. It is situated on the edge of a deep and picturesque glen of Mount Lebanon, on the opposite side of which the palace Bteddin was the summer residence of the Christian governor of Lebanon. Pop. 8000, mostly Maronites.

**Deism** properly means belief in a God, as opposed to atheism; but the term used to express this sense is *Theism* (q.v.). On the other hand, Deism is generally understood to imply the denial of a revelation; and a Deist is one who holds the existence and providence of God, but grounds his belief on reason and evidence, rejecting the testimony of a revelation. The name is often used vaguely by way of reproach.

The term Deists, or Freethinkers, is usually employed to designate a series of writers who appeared in England in the 17th and 18th centuries, and sought to establish Natural Religion upon the basis of reason and free inquiry, in opposition to all positive religions, and without reference to supernatural revelation. They were critical, if not hostile, in their attitude towards Scripture, and denied miracles, the Trinity, and atonement by Christ; and they may fairly be taken as constituting one movement, though they by no means formed one school or agreed in the details of their teaching. Thus some believed and others rejected the immortality of the soul and human free-will, and they did not all teach the same doctrine as to

the relation of God to the universe, some being almost pantheistic. They were not for the most part accurate scholars, and were rather acute than profound thinkers; but though their influence on English thought seemed for a time to be blotted out, they contributed largely to the progress of rationalism in Europe. The chief deists were Lord Herbert of Cherbury, called the 'Father of Deism' (died 1648), Blount, Tindal, Woolston, Toland, Lord Shaftesbury, Lord Bolingbroke, Collins, Morgan, and Chubb (died 1746). See the separate articles on these writers, also CHURCH HISTORY, RELIGION, RATIONALISM; Leland, *View of the Deistical Writers* (1754); Lechler, *Geschichte des Englischen Deismus* (1841); Hunt, *Religious Thought in England* (1872); Stephen, *English Thought in the 18th Century* (1876); Benn, *English Rationalism in the 19th Century* (1906); Robertson, *History of Free Thought* (1906).

**Déjazet**, PAULINE VIRGINIE, a great French actress, born at Paris, 30th August 1797. On the stage before she was five years old, she grew up playing children's and boys' rôles with marvellous precocity of intelligence and grace, but first awoke to a sense of her real greatness in an engagement at Lyons, where her playing of such parts as were then known as *soubrettes* endeared her to the citizens. In 1821 she began to play at the Gymnase, but her greatest triumphs were won at the Théâtre du Palais-Royal, whither she betook herself in 1834. From 1844 to 1849 she played at the Variétés, next at various Paris theatres, in the provinces, and at London, till 1859, when she undertook the management of the Folies-Dramatiques. She left the boards in 1868, next year received a pension of 2000 francs, and died 1st December 1875. See *Lives* by Lecomte (1866 and 1892) and Duval (1876).

**Dekker**, THOMAS, dramatist, was born in London about 1570. He was a very prolific writer, but only a few of his plays were printed. In 1600 he published two comedies, *The Shoemaker's Holiday*, or *the Gentle Craft*, and *The Pleasant Comedy of Old Fortunatus*. The first of these pieces is one of the pleasantest of old plays, and the second abounds in poetry of rare beauty. Dekker's next play was *Satirromastix*, or *the untrussing of the Humorous Poet* (1602), in which Ben Jonson was held up to ridicule. In *Every Man out of His Humour* and *Cynthia's Revels* Jonson had made some satirical reflections on Dekker; and in *The Poetaster* (1601) he had assailed Dekker and Marston with bitter vehemence. Long afterwards, in 1618, Jonson told Drummond of Hawthornden that Dekker was a knave. Before the quarrel Jonson and Dekker had worked in harmony; in 1599 they wrote together two plays (which have not come down), *Page of Plymouth* and *Robert the Second*. In 1603 Dekker published a pamphlet entitled *The Wonderful Year*, which gives a heart-rending account of the sufferings caused by the plague. To the same year belongs the very amusing tract *The Bachelor's Banquet*, in which he describes with gusto the ills to which henpecked married men are forced to submit. His most powerful writing is seen in *The Honest Whore* (1604), of which the second part was published in 1630. Middleton assisted him in the first part. In 1607 he published three plays written in conjunction with Webster, the *Famous History of Sir Thomas Wyatt* (which has descended in a mutilated state), *Westward Ho*, and *Northward Ho*. A pamphlet entitled *The Bellman of London* (1608) gives a very lively account of the vagabonds of London; and Dekker pursued the subject further in *Lanthorn and Candlelight* (1608), which passed through several editions. The most famous of his

pamphlets is *The Gull's Hornbook* (1609), in which the life of a town-gallant is raucily depicted. *The Roaring Girl* (1611) was partly written by Dekker; but Middleton must take the chief credit for that excellent comedy. From 1613 to 1616 Dekker was confined in the King's Bench prison. Earlier in his career he had spent some time in the Counter prison. In each case his debts were the cause of his imprisonment. With Massinger he composed the *Virgin Martyr*; and Lamb was doubtless right in ascribing to Dekker the most beautiful scene (II. i.) in that play. *The Sun's Darling*, licensed for the stage in 1624, but not printed till 1656, was written in conjunction with Ford. A powerful tragedy, *The Witch of Edmonton* (posthumously published in 1658), was written by Dekker, Ford, and Rowley. We hear of Dekker in 1637, when he republished his *Lanthorn and Candlelight* under the title of *English Villainies*, and then he drops out of notice. His plays were collected in 1873 (4 vols.), and his pamphlets were republished in Grosart's 'Huth Library' (5 vols.). F. P. Wilson edited the *Plague Pamphlets* in 1926. See Tucker Brooke's *Tudor Drama* (1912); Miss Leland Hunt's study (1912); and Swinburne's essay.

**De la Beche**, SIR HENRY THOMAS, a well-known geologist, was born near London in 1796. He was educated at the military school at Great Marlow, and entered the army in 1814. Three years after, he became a Fellow of the Geological Society, of which he was afterwards made secretary, and eventually president in 1847. In 1820, while residing in Switzerland, he published a paper on the temperature and depth of the lake of Geneva. In 1824 he visited Jamaica, and published a paper on the geology of the island. Other works are a *Manual of Geology* (1831), *Researches in Theoretical Geology* (1834), and a *Geological Observer* (1853). He undertook to form a geological map of England; and soon after he had begun, the government, sympathising with his design, instituted the Geological Survey, and placed him at its head. He was founder of the Geological Museum in Jermyn Street, and of the School of Mines. In 1848 he received the honour of knighthood; and in 1853 was elected a corresponding member of the Academy of Sciences of Paris. He died 13th April 1855.

**De la Borde**, HENRY FRANÇOIS, COUNT, a French general, born at Dijon, 21st December 1764. The son of a baker, he enlisted at the outbreak of the Revolution, and by 1793 had risen to be general of brigade. He distinguished himself in Spain at the Bidassoa (1794), next commanded a division on the Rhine under Moreau, was governor of Lisbon in 1807, and was ennobled in 1808. He declared for the emperor on his return from Elba. He died 3d February 1833.

**Delacroix**, EUGÈNE, a French painter, chief of the Romantic school, was born at Charenton-Saint-Maurice, near Paris, 26th April 1799. At the age of eighteen he entered the atelier of Pierre Guérin, a follower of David, and came under the far more powerful influence of his fellow-pupil, Géricault. In 1822 he exhibited his first work, 'Dante and Virgil,' the novel force of which attracted much attention and won the praise of M. Thiers among others. In 1824, Delacroix, who was now at the head of the new school of young painters, produced the 'Massacre of Scio,' which was entirely repainted after the artist had studied a work of Constable's. The July revolution left its impress on Delacroix, and in 1831 appeared his 'Liberty directing the people on the Barricades.' In 1832 he made a voyage to Morocco, where he familiarised himself with novel effects of light and costumes. From this period, Delacroix continued to send forth picture after picture, besides decorat-

ing many public buildings and churches. He also executed a number of lithographs, including a series illustrating Hamlet, and one dealing with Faust, of which Goethe wrote that he found 'in these images all the impressions of his youth.' In 1857 he was chosen by the Institute to fill the place of Delacroix. He died 13th August 1863. The most striking quality of Delacroix's art is its invention, its impetuous imaginative force and vitality. He aimed at a powerful and dramatic expression of passion and emotion, and in the pursuit of this aim a sense of beauty was frequently lost. He was an admirable colourist, and his admirers have ranked him with Veronese and Rubens. His drawing, sometimes incorrect, is always spirited and full of vigour. See Lives by Moreau (1873), Burty (1880), and Chesneau (1885); a book by Mrs Bussy (1907); and his *Journal* (1898).

**Delagoa Bay**, a large inlet of the Indian Ocean, in Portuguese East Africa, was discovered by one of Vasco da Gama's lieutenants in 1502. It is 25 miles wide, and for size and accommodation is the finest natural harbour in South Africa; in spite of islands and shoals its navigation is safe and easy, and the anchorage is commodious and well sheltered. The settlement of Lourenço Marques (capital of the province) and surrounding country have been notoriously unhealthy; but drainage and other improvements have been carried out. The rivers Maputa, Tembe, and Umbelosi (the two latter joining to form the English River), and the Komati, fall into Delagoa Bay. The proximity of Delagoa Bay to the Transvaal goldfields greatly increased its commercial and political importance. Railway lines connecting with Pretoria (350 miles from the coast) and with Johannesburg, &c., were completed in 1890-95, and both before and during the war of 1899-1902 proved invaluable to the Transvaal. Another (1906-12) runs to Swaziland. See LOURENÇO MARQUES, MOZAMBIQUE.

**De la Mare**, WALTER, poet and novelist, was born 25th April 1873 at Charlton, in Kent. His *Songs of Childhood*, published in 1902 as by 'Walter Ramal,' and much revised in later editions, his prose romance, *Henry Brocken* (1904), his volume of *Poems* (1906), his children's monkey-story, *The Three Mulla Mulgars* (1910), and his fascinating novel of the occult, *The Return* (1910), were recognised as books of high promise. That promise was fulfilled in *The Listeners* (1912), and bettered in *Peacock Pie* (1913) and in *Motley and other Poems* (1918). As a romanticist and a musician in words Mr De la Mare has reminded his critics of Coleridge, with something of Keats added. His art and his atmosphere are yet those of no sorcerer's apprentice, but of an authentic magician. Moreover, he has faced the problem of the real universe, and sometimes he has found himself upon the cold hillside, as in his prose novel *Memoirs of a Midget* (1921) and in *The Veil and other Poems* (1921). But he can still regain access to his *märchen* world, in whose enchantments and humour children and older readers delight alike. His *Collected Poems* were published in 1920, a book of short stories, *The Riddle*, in 1923, *Ding Dong Bell* and *Crossings* in 1924.

**Delambre**, JEAN JOSEPH, astronomer, born at Amiens, 29th September 1749, taught, and studied physics and astronomy under Lalande. The discovery of Uranus by Herschel in 1781 gave him the first opportunity of attracting the attention of the learned world in general by preparing tables of the motion of the new planet. Soon after, he commenced the construction of new solar tables, and tables of the motions of Jupiter and Saturn. Along with Méchain, he was appointed by the French government, in 1792, to measure the arc of the

meridian between Dunkirk and Barcelona, which was completed in 1799 (see METRE, ARAGO). He was elected member of the Academy, and in 1803 perpetual secretary of the mathematical section of the Institute. The result of his measurements appeared in his great work, *Base du Système Métrique Décimal* (1806-10). In 1807 he obtained the chair of Astronomy at the Collège de France, rendered vacant by the death of Lalande, his master and friend. In 1814 he was appointed a member of the Council of Public Instruction. He died at Paris, 19th August 1822. Delambre received a multitude of honours during his lifetime. He was a member of most of the learned bodies in Europe, and an officer of the Legion of Honour. His writings are very numerous.

**Delane**, JOHN THADEUS, editor of the *Times* newspaper, was the second son of a barrister, and was born in London, 11th October 1817. He received the earlier part of his education in private schools, and at King's College, London, and finally went to Magdalen Hall, Oxford, where he took his degree in 1839. At the university, he was more famous for horsemanship than reading, and though bright and active-minded, he never professed to be a scholar. After leaving Oxford he studied life in many forms, walked the hospitals, was called to the bar, and reported in the House of Commons and on circuit. Mr Walter had early marked Delane's capable character, and soon placed him on the *Times* staff; and in May 1841, not yet twenty-four, he became its editor. For thirty-six years Delane held this post, aided, however, for the greater part of this period by his brother-in-law and college friend, George Dasent (q.v.). Under his editorship, the *Times* attained a prodigious circulation, and an influence unparalleled in the history of journalism. He wrote no articles, but he contributed excellent reports and letters. He merged his personality in his paper, and the history of his later life is the history of the extraordinary influence wielded by the leading journal. His exposure of the railway mania, his vehement attacks upon the management of the Crimean war, and his strong opposition to England's assisting Denmark in 1864, are among his best-remembered acts. He was singularly shrewd in weighing public opinion, possessed remarkable foresight, and seldom made a mistake. Having resigned the editorship in 1877, he died two years later, 22d November 1879. His successor was Thomas Chenery. A Life by Sir G. Dasent, withheld in deference to Mr Walter, was published in 1908, one by Sir E. T. Cook in 1915.

**Delany**, MRS (Mary Granville), was born at Coulston, Wiltshire, 14th May 1700. The niece of Lord Lansdowne, she married first, in 1718, 'fat, snuffy, sulky' Alexander Pendarves (1659-1724); and secondly, in 1743, the Rev. Patrick Delany (1685-1768), an Irish divine, Swift's friend, and the author of a dozen volumes. After his death she lived chiefly in London, till her own death at Windsor on 15th April 1788. Her much-admired 'paper mosaics,' or flower-work, have long since faded; but she is remembered through her patronage of Miss Burney, and by her *Autobiography and Correspondence* (6 vols. 1861-62). See also G. Paston, *Mrs Delany, a Memoir* (1900).

**De la Pole**. See POLE.

**De la Ramée**, LOUISA. See OUIDA.

**Delaroche**, HIPPOLYTE, known as PAUL (1797-1856), painter, was born at Paris. He studied under Baron Gros, and excited admiration in 1824 by his 'Joan of Arc before Cardinal Beaufort,' followed by 'Death of Queen Elizabeth' (1827). In 1831 he produced the 'Princes in the Tower;' in 1833, 'Cromwell contemplating the Corpse of Charles I.:' in 1834 his 'Execution of

Lady Jane Grey,' and in 1837 his 'Charles I. insulted by the Parliamentary Soldiers,' and his 'Strafford receiving Laud's Blessing on the Way to Execution.' From this period until 1841 he was engaged on what is probably his grandest work—the series of paintings on the wall of the semicircular saloon of the École des Beaux Arts, in the execution of which he was aided by Armitage and other pupils. Later works were 'Marie Antoinette before the Tribunal' (1851); 'The Finding of Moses' (1852); 'Calvary' (1853); and 'The Floating Martyr.' He also executed striking portraits of Guizot (1838), Thiers (1856), &c. The characteristic excellences of Delaroche are picturesqueness of conception, precision of handling, and accuracy of drawing. He has been accused, however, of want of fire, imagination, and depth, and it must be admitted that he very rarely, if ever, exhibits the highest qualities of creative genius. Delaroche was made a member of the Institute in 1832, and professor of Painting in the École des Beaux Arts in 1833. See Rees, *Vernet and Delaroche* (1880).

**De la Rue, WARREN**, an eminent electrician, was born in the island of Guernsey, 18th January 1815. He was educated at Paris, and early entered his father's business—the manufacture of paper-ware—for which his inventive ability and scientific knowledge enabled him to devise many new machines and processes. He took an active part in the Exhibitions of 1851 and 1862; was a member of the International Electrical Congress in Paris in 1861; and was president of the Royal Astronomical Society, of the Chemical Society, and the London Institution. In 1878 he succeeded Spottiswoode as secretary of the Royal Institution, and in 1880 was elected a corresponding member of the French Académie des Sciences in the department of astronomy. His scientific work, done at his observatory at Cranford and at his private physical laboratory, was of the highest value in the departments of astronomical photography and electricity, and its results were communicated from time to time to the Royal Society and the French Académie des Sciences. He died 19th April 1889.

**Delaunay, LOUIS ARSENE**, a French actor, was born 21st March 1826, at Paris, and made his début in October 1846 at the Odeon. In the year 1848 he first trod the classic boards of the Théâtre Français in the rôle of Durante, and here he soon procured an engagement and became secretary to the theatre in 1850. He retired in 1857, and died in 1903. One of the most accomplished actors on the French stage, he found some of his greatest parts in the plays of Hugo, Paileron, De Musset, and Augier.

**Delavigne, JEAN FRANÇOIS CASIMIR**, dramatist, satirist, and lyricist, was born at Le Havre on April 4, 1793. He became one of the most popular writers in France, after the publication in 1818 of his *Messénienes*, satires directed against the monarchy of the Restoration. He then turned his attention to dramatic authorship and produced *Les Vêpres Siciliennes* (1819), a tragic piece, which was followed by the comedies, *L'École des Vieillards* and *Les Comédiens* (1821). He was made an academicien in 1825. As a lyricist and satirist, he espoused the cause of the patriots in Italy, Greece, and Poland, and of the democratic party in France, but although he appears to have been a sincere politician, he failed to give natural and original expression to his convictions. His tragedy of *Louis XI.*, which was partly founded on *Quentin Durward*, and an adaptation of which is familiar to English playgoers, was brought out in 1833. Among his other dramas were *Le Paria*, *Marino Faliero*, *Les Enfants d'Edouard*, *Don Juan d'Autriche* (1835), and *La Fille du Cid* (1839). He died on December 11, 1843. He had no true poetic

faculty; neither was he a skilful dramatist, though his plays, when first produced, gained considerable popularity. In his day he was supported by the opponents of the Romantic school, but his mediocrity has come to be recognised by critics of all parties.

**Delaware**, one of the Atlantic States of the American Union, forms a part of a peninsula lying between the lower reaches of the Susquehanna and Chesapeake Bay on the west, and the Delaware River and Bay and the Atlantic on the east. The bay was named in 1611 from Thomas West, Lord de la Warr, first governor of Virginia. The state is bounded N. by Pennsylvania (where the boundary is an arc of a circle), E. by the Delaware River and Bay and the Atlantic, and S. and W. by Maryland. With an area of 2000 sq. m., or about that of Northumberland, it is the smallest of all the states except Rhode Island; in 1920 it was the smallest of all in population, except Nevada and Wyoming. Save in a small hilly section in the north nearly all the surface is low and level, and in the extreme south there is much swampy land; while the most southerly two-fifths of the area is in great part a sandy region. The hill-district in the north presents a stony surface overlying azoic rocks, such as gneiss and granite, with patches of serpentine and limestone. A strip of highly fertile red clay lies south of the hill-country; and next southward occurs a productive and fossiliferous greensand formation, succeeded by a somewhat sandy belt, less fertile than the greensand, although the greater part of its extent is by no means unproductive. The coast-region has many salt-marshes, some of them dyked, and thus rendered tillable; and farther inland is a considerable body of extremely rich alluvial soil. The western border of the state is generally well wooded, and in some places flat and marshy. The rivers of Delaware are mostly small, but many are navigable. In the north kaolin and iron ore are found; bog ore or limonite occurs to some extent in other parts; and granite is largely produced.

Delaware is divided into three counties, New Castle, Kent, and Sussex. It is well provided with railroad facilities, and is crossed by a canal connecting the Delaware and Chesapeake bays. The northern section has large and varied manufacturing interests. Fishing and the taking of oysters and crabs are important industries in Sussex county, and along the shores and tidal streams. Peaches and the various small fruits, as well as market-garden products, are leading articles of export; and fruit-evaporating and canning are important. The principal cereal crops are maize, wheat, and oats. Pop. (1880) 146,608; (1900) 184,735; (1910) 202,322; (1920) 223,003. The principal towns are Wilmington, the centre of manufacturing industries, New Castle, Dover, the state capital, and Smyrna.

Delaware's first permanent white settlements were made by Swedes and Finns, who settled at Christiana (Wilmington) in 1638; for a Dutch settlement of 1613 at Hoornkill (now Lewes) was destroyed a year later by the Indians. The colony of New Sweden included a small part of Pennsylvania and a section of New Jersey. For several years the Dutch and Swedes contended for the possession of this region, till in 1655 it passed under Dutch sway. After the transfer of New Amsterdam (now New York) to the English rule in 1664, Delaware, like the stronger colony, became English also. It was governed from New York until 1682, when William Penn became proprietary of the three Delaware counties, which, however, were never considered as forming any part of Pennsylvania, to which colony they were attached. In 1776 it was made a separate state, and a constitution was

adopted, which was set aside by another in 1791. Delaware was a slave-state until the war of 1861-65, but took no part in the secession movement. The state sent 14,000 soldiers to the northern armies, but many from the southern districts joined the Confederates in the war.

**Delaware**, THOMAS WEST, LORD, the first governor of Virginia, arrived there from England in June 1610, but nine months later was prostrated by ill-health, and died in 1618.

**Delawares**, a tribe of Algonquins (q.v.) formerly inhabiting the Delaware basin, now, after several removals, mostly incorporated with the Cherokees in Oklahoma.

**Delbrück**, HANS, historian, born at Bergen in Rugen, 11th November 1848, studied at Heidelberg, Greifswald, and Bonn, was tutor to a princess, edited the *Preussische Jahrbücher* 1883-1920, sat in the Reichstag 1884-90, became professor of history at Berlin in 1885. He wrote a *Geschichte der Kriegskunst im Rahmen der politischen Geschichte* (1900-20), and many other works on kindred subjects, including responsibility for the Great War and its outcome.

**Delcassé**, THÉOPHILE, French statesman, born 1st March 1852 at Pamiers (Ariège), as minister for the colonies (1894-5) furthered French enterprise in Africa, as foreign minister (1898-1905) settled the Fashoda difficulty which had arisen out of his colonial policy, mediated between Spain and America, fostered the Russian alliance, composed differences with Britain, and resigned on the Morocco crisis. In 1911-13 he was minister of marine, in 1913-14 ambassador to Russia, and in 1914-15 foreign minister. He died in February 1923.

**Del Credere Commission**, the higher rate or allowance charged by a factor or agent, in respect of which he guarantees the solvency of the purchaser, and renders himself personally liable to his principal in the case of the purchaser's failure to pay the price of the goods sold. It is not necessary that the contract be in writing. The premium is often double an ordinary selling commission.

**Deleb Palm**, or ETHIOPIAN FAN-PALM (*Borassus aethiopum*), is very common and widely distributed throughout Central Africa, where it often practically replaces the date palm in the domestic economy of many negro tribes. Its large hard nut is eaten fresh, but also largely planted until germination has fairly commenced; the young embryo thus laden with sugar, &c., is then eaten raw or cooked.

**Delectus** (Lat., 'a selection'), the old name often applied to a selection of passages from Latin or Greek writers graduated in difficulty for the use of young learners. None is so famous as Valpy's.

**Deledda**, GRAZIA, Italian novelist of violent and sombre Sardinian life, was born at Nuoro in Sardinia in 1872.

**Delegation** (Ital. *delegazione*), the term formerly applied in Lombardy, Venice, and the States of the Church, both to the governor and governing court of a province and to the province itself. The number of such provinces varied, but was at one time nineteen. The delegate was always a prelate, and directly appointed by the pope. If he was a cardinal, he was called a Legate, and his province a Legation. See also AUSTRIA-HUNGARY.

**Delescluze**, LOUIS CHARLES, French commandant, was born at Dreux, 20th October 1809. His politics early drove him from France to journalism in Belgium, but the February revolution opened to him a career in Paris, where his clever and facile pen quickly brought him popularity,

imprisonment and a fine of 10,000 francs. Again at Paris in 1853, he was sentenced to two years' imprisonment, and was next transported to Cayenne, where he remained till 1859. His experiences of his sufferings he gave in *De Paris à Cayenne: Journal d'un Transporté* (1867). After his return he was quiet for some years, until his journal, *Réveil*, started in 1868 to advocate the doctrines of the International, brought him anew into trouble. In the history of the Paris Commune he played a prominent and responsible part. He died on the last barricade, 28th May 1871.

**Delfshaven**, an old town in South Holland on the Maas,  $1\frac{1}{2}$  mile W. of Rotterdam, with which city it was incorporated in 1886.

**Delft**, one of the most ancient towns of South Holland, is situated on the Schie, 8 miles N.W. of Rotterdam by rail, and is intersected by numerous canals. Delft was noted from the 16th to the 18th century for its delft-ware (see POTTERY), but has now entirely lost its high reputation for this manufacture, and not more than a few dozen persons are engaged in making earthenware. Of several interesting buildings, one, the town-hall (1618), is a picturesque and richly adorned edifice. The New Church (1476) contains a monument, more ornate than tasteful, to the memory of William I. of Orange, who was assassinated here, 10th July 1584. It also contains the tomb of Grotius, and the burial-vaults of the present royal family of Holland. The Old Church, a building of some note, contains the tomb of the naturalist, Leeuwenhoek, and of the great admiral, Van Tromp. Delft has also a state arsenal, an East Indian college, a polytechnic, and several hospitals. There are some manufactures of fine carpets, casks, baskets, and trade in glass, spirits, and butter. Pop. 40,000.

**Delhi** (*Dehli*), a city detached in 1912 from the Punjab and made capital of the Indian empire, stands on the right bank of the Jumna, 113 miles NNW. of Agra, and 954 NW. of Calcutta. It is walled on three sides, has ten gates, and stands on high ground, the grand series of buildings forming the famous palace of Shah Jehan, now the Fort, looking out over the river and a wide stretch of wooded and cultivated country. To the north, about a mile distant, rises the historic 'ridge,' crowned with memorials of the Mutiny, and commanding a fine view of the city, the domes and minarets of which overtop the encircling groves. The gardens in the city, the suburbs, and the neighbouring country are all richly wooded. The palace buildings, the splendid heritage of Mogul sovereignty, comprise the cathedral-like entrance-hall, the *diwan-i-khas*, or audience-hall, the *diwan-i-am*, the *rang mahal*, and several lesser pavilions, covering in all an area of 1600 feet by 3200, exclusive of gateways. The beautiful inlaid work and carving of these buildings are the admiration of the world, and the *diwan-i-khas* is worthy of its famous inscription: 'If there is a heaven on earth, it is this—it is this!' In the heart of the city stands the Jama Masjid ('great mosque'), one of the largest and finest structures of the kind in India, which also owes its origin to Shah Jehan. Among the notable monuments in the neighbourhood are the imperial tombs, including that of Hamayun, second of the Mogul dynasty; the old Kala Masjid, or black mosque; and the famous Kutab Minar, 10 miles to the south. The Minar, erected by Kutab-ud-din, founder of a dynasty, early in the 13th century, is 238 feet high, and tapers gracefully from a diameter of 47 feet at the base to 9 feet at the summit. It incloses a winding staircase, and is garlanded with inscriptions from the Koran. Modern Delhi is noted for its broad main streets, the chief being the Chandni Chauk, or Silver

Street, with its high clock-tower, and the institute and museum. Delhi having been selected to supersede Calcutta as capital of India, a district to the south known as Raisina, between the Jumna and the southerly continuation of the ridge, was set apart in 1913 for the new city, which was planned by Sir Edwin Lutyens and Mr Herbert Baker, with Government House, secretariats, legislative chambers, public offices, museums, colleges, cathedrals, parks, courts, &c. The Delhi College, once a famous oriental school, has been abolished, government having withdrawn the collegiate staff of teachers to concentrate the grant upon the central institution at Lahore; but a new university was founded in 1922. Delhi has a large trade in wheat and other produce, and its bazaars are noted for gold and silver work, precious stones, shawls, and costly fabrics. It is a great banking centre. Across the river is the ruined fort of Salimgarh. Pop. (1891) 192,579; (1901) 208,385; (1911) 232,837; (1921) 304,420, more than half Hindus.

The name Dilli or Dillipur first appears in the 1st century B.C. and is connected with the famous iron pillar of Raja Dhava, a solid shaft of metal, set up in the 3d or 4th century, which is 16 inches in diameter, and 50 feet long, and which is so firmly planted that only half of it is above ground. This indisputable relic bears a Sanskrit inscription, in which the name of the city is mentioned. Delhi was the capital of the Afghan or Pathan, and afterwards of the Mogul, empire. It was taken by a British army under Lord Lake, 8th September 1803, and has ever since—if we except the brief period when it was held by the mutineers in 1857—continued under British rule. In our own time Delhi has been rendered memorable by the events of 1857. The march on the city of the mutineers from Meerut; the terrible 11th of May; the explosion of the powder-magazine by Willoughby and his heroic band; the assault, when the city was won (20th September) gate by gate and quarter by quarter—a success saddened by the death of the gallant Nicholson; the subsequent daring capture of the king of Delhi by Hodson of Hodson's Horse; and the capture and shooting of his miscreant sons by the same officer, are memorable events in Indian history. A memorial to Willoughby was erected by government in 1888. In 1877 Delhi was the scene of the Durbar at which Queen Victoria was proclaimed Empress of India; in 1903 of the Durbar to celebrate the accession of Edward VII., and in 1911 King George and Queen Mary attended the coronation Durbar there. Delhi is now the most Europeanised of all the cities in the interior. An earthquake did much damage in 1905. See H. C. Fanshawe, *Delhi Past and Present* (1902).

**DELHI, PROVINCE OF.**—The province of Delhi forms a small enclave administered by a chief commissioner. Its area is 557 square miles and population about 498,000, including the city of Delhi. The old district of Delhi has been broken up. Those portions which are not included in the enclave have been absorbed in the districts of Rohtak and Gurgaon. Those two districts and Hissar, Karnal, Ambala, and Simla, which, with Delhi, formed the division of Delhi, have been formed into a new division called the Ambala Division (Punjab). A small part of the district of Meerut (U.P.) has been included in the Delhi Province.

**Delibes, LÉON**, a French composer, born in 1836 at St Germain du Val, in the Sarthe, entered the Paris Conservatoire in 1848, and in 1855 produced an operetta, *Deux Sacs de Charbon*. At the Grand Opéra, where he became second director in 1865, his music for the ballet *La Source* (1866) met with great success, and his ballet-music for *Coppélia* (1870), his finest work, secured his

position as a composer. He wrote music for a third ballet and for three comic operas, one of which, *Le Roi l'a dit* (1873), became very popular. In 1880 Delibes was appointed professor in the Conservatoire. He died 16th January 1891.

**Delilah** (signifying, according to Bertheau, 'the delicate'; according to Ewald, 'the traitress'), the Philistine woman who betrayed Samson (q.v.).

**Delille, JACQUES**, a writer extravagantly overrated in his lifetime, was born near Aigues-Perse in Auvergne, on June 22, 1738. He was an illegitimate child, and was brought up by charity. Educated at the Collège de Lisieux in Paris, he distinguished himself as a scholar, and obtained a professorship in Amiens. His verse translation of the *Georgics*, published in 1769, had an extraordinary vogue, and was extolled far beyond its merits by Voltaire and other critics. Its author was made an academicien in 1774, and, after holding a canonry at Moissac, was presented by the Comte d'Artois with the abbacy of Saint-Severin, the income of which amounted to 30,000 livres a year. *Les Jardins*, a didactic poem which Delille published in 1782, found a vast body of readers, and was generally accepted as a masterpiece. The outbreak of the Revolution compelling Delille to leave France, he travelled in Switzerland and Germany, and then removed to London, where he occupied himself for eighteen months in translating the *Paradise Lost*. After his return to France in 1802, he produced a translation of the *Æneid* (1804) and several didactic and descriptive works in verse—*L'Imagination* (1806), *Les Trois Règnes* (1809), and *La Conversation* (1812). He became blind in his old age, and died on May 1, 1813. During his life he was not only regarded by his countrymen as the greatest French poet of the day, but was even declared to be the equal of Virgil and Homer. His fame, however, suffered a rapid eclipse, and his lack of poetic genius is now generally admitted. He was merely a fluent versifier, whose knack of turning out ingenious paraphrases exactly suited the taste of his contemporaries. See Sainte-Beuve's *Portraits Littéraires*, vol. ii.

**Deliquescence** is the term applied to the property which certain substances have of absorbing moisture from the air, and becoming damp, and even running into liquid. Caustic potash, and the chlorides of calcium and magnesium, are examples of substances which undergo this change.

**Delirium** belongs essentially to the group of the confusional or toxic insanities, although the term is generally restricted to the mental disturbances accompanying acute febrile conditions. The toxins which cause its symptoms may be of various kinds—e.g. (1) The infective organisms of various fevers, pneumonia, or acute rheumatism; (2) the toxins produced within the system as the result of metabolic disorders, excess or diminution of the secretion of certain endocrine glands, sunstroke, diseases of such excreting organs as the kidneys, or inanition from wasting diseases or starvation; (3) toxic substances voluntarily introduced into the system, such as alcohol.

The symptoms of delirium include disintegration of the normal mental processes, extending from slight disorders of consciousness to complete disorientation, muttering, delirium, and coma. In addition, illusions of the senses are common, the patients misinterpreting sounds, objects, and the identity of persons near them. In more severe cases hallucinations, both of sight and hearing, may occur, and these are usually accompanied by delusions of various kinds, but of an unformed and fleeting character.

As a rule the subjects of delirium are restless and sleepless, but other symptoms tend to vary greatly in the course of the attack. At times the patients may be violent and oblivious of their surroundings; at other times, though apparently self-restrained and responsive, they may yet be under the influence of delusions and hallucinations.

The symptoms of delirium are partly conditioned by the nervous constitution of the individual, and partly by the nature and virulence of the toxæmia.

**Delirium Tremens** is the term employed to denote one of the acute phases arising in the course of *Chronic Alcoholism* (q.v.). It may be precipitated, either by a period of excessive drinking, by severe shock of a mental or physical kind, or by acute illnesses, such as fever or pneumonia. It reveals itself at first by general uneasiness, restlessness, and sleeplessness. These initial symptoms usher in the delirium, always accompanied by constant muscular tremors. The delirium presents the main features of mental confusion, illusions, hallucinations and delusions, referred to in the preceding article, but it is more coloured by anxiety and the emotion of fear than other forms of delirium. An attack generally lasts about three days, but it may persist for six or seven days, and, so far as is at present known, there is no means of shortening its duration. The chief danger lies in the great risk of exhaustion to which the patients are liable. The only rational treatment consists in combating the tendency to exhaustion by means of sedatives, hypnotics, and the administration of such easily assimilable nutriment as the disordered digestive tract can absorb.

**De Lisle.** See LÉCONTE, ROUGET.

**Delitzsch,** a town of Prussian Saxony, on the Lösser, 12 miles N. of Leipzig by rail, with manufactures of cigars, straw, leather, ivory, and wooden goods; pop. 12,000.

**Delitzsch, FRANZ,** a learned theologian and Hebraist, born at Leipzig, 23d February 1813, studied theology and orientalia at the university there, and became professor of Theology at Rostock in 1846, whence he was called to Erlangen in 1850, and to Leipzig in 1867. Delitzsch's vast learning and exegetical sagacity combined to give him a foremost place among the more conservative German theologians, while his great personal influence over a generation of Leipzig students, and a long series of profoundly learned books, contributed enormously to extend a sound knowledge of Old Testament exegesis not only in Germany, but in England and America. His earliest works were in the field of the post-biblical Jewish literature, followed by his commentaries. Later works are his *System der biblischen Psychologie* (1855), *System der christ. Apologetik* (1869), *Jesus und Hillel* (1867), *Jüd. Handwerkerleben zur Zeit Jesu* (1868). His commentary on Genesis (1887) made large concessions to the critical theory of the Pentateuch. He died 3d March 1890.—His son, **FRIEDRICH DELITZSCH** (1850–1922), made a great reputation as an Assyriologist by his *Assyr. Studien* (1874), his translation of George Smith's *Chaldean Account of Genesis* (1876), *Wo lag das Paradies?* (1881), his *Assyr. Wörterbuch* (1887 et seq.), his *Assyrische Grammatik* (1903), and his *Babel und Bibel* (1904).

**Delius, FREDERICK,** born in 1863 of German parents at Bradford in Yorkshire, forsook a business career to become an orange planter in Florida, and there he gave his leisure to musical studies, continued after some years at the Leipzig conservatorium. From 1890 he lived in Paris or elsewhere in France. A remarkable composer, he belongs to no school. Among his works are a *Légende* for violin and orchestra (1890); a fantasia

overture *Over the Hills and Far Away*; several operas (*Konga*, *Village Romeo and Juliet*, *Fennimore and Gerda*, &c.); concertos; a *Requiem*; settings of passages from Whitman and Nietzsche; and *Brigg Fair* and other symphonic poems. See a book by P. Heseltine (1923).

**Delius, NIKOLAUS,** a distinguished German Shakespearean critic, was born at Bremen, 19th September 1813, and studied philology at Bonn and Berlin, and in England and France. He finally settled in 1846 at Bonn, where he died 18th November 1888. His early lectures were on Sanskrit and the Romance tongues, but he afterwards devoted himself to the English language and literature, and published several works on Shakespeare. His edition of Shakespeare (Elberfeld, 7 vols. 1854–61) is an acknowledged masterpiece, its notes a marvel of terse sagacity.

**Delivery.** See DEED, SALE OF GOODS.

**Della Cruscan School.** About the year 1785 a number of English residents at Florence endeavoured to amuse their lagging hours by writing verses, which they published under the title of *The Florence Miscellany*. The insipidity, affectation, and fantastic silliness of these productions transcend belief; yet such was the poetic poverty of the time, that they soon found a crowd of admirers and imitators. Taking the name of a Florentine Academy (q.v.), the Della Cruscan now began to print their precious lucubrations in England, chiefly in two daily newspapers called the *World* and the *Oracle*. 'While the epidemic malady was spreading from fool to fool,' as Gifford pungently says, one of the brotherhood, a Mr Robert Merry, came over from Florence, and 'immediately announced himself by a sonnet to Love.' It was answered by one, 'Anna Matilda' (Mrs Cowley), who (as was the custom) praised it immoderately in language even more absurd than Merry's own. The fever now turned to a frenzy: Laura Maria, Carlos, Orlando, Adelaide, and a thousand other nameless names, caught the infection; and from one end of the kingdom to the other all was nonsense and Della Crusca. But retribution followed, for Nemesis watches the course of poetry as sharply as that of politics. In 1794 Gifford produced his *Baviad*, and in 1796 his *Mæviad*. Rarely has literature witnessed such a scalping. It completely killed the school, and, indeed, it is only in these two poems that the memory of most of the unhappy Della Cruscan songsters has been preserved—an immortality which may be compared with that conferred by the *Newgate Calendar*.

**Dellys,** a port of Algeria, 50 miles E. of Algiers, with a French garrison; pop. 14,000.

**Delmenhorst,** a town of Germany, in Oldenburg, 8 miles W. of Bremen, has woollen, jute, and linoleum manufactures; pop. 20,000.

**De Lolme, JOHN LOUIS** (1740–1806), born at Geneva, was an advocate there, but about 1769 came to England, where, in spite of his literary activity, he lived for several years in great poverty, always in debt and repeatedly in prison. Inheriting a small property, he returned to Switzerland in 1775. His principal work is *The Constitution of England; or an Account of the English Government; in which it is compared both with the Republican Form of Government and the other Monarchies of Europe*, first published in French at Amsterdam in 1771; the English translation, by another hand apparently, did not appear till 1775. The work, which flattered England, threw no new light on the subject, long enjoyed a high reputation, and reached a tenth edition (with Life, 1853). Its author was called by Isaac D'Israeli 'the English Montesquieu.' In 1772 he published anony-

mously in English *A Parallel between the English Government and the former Government of Sweden*: ten years later, his *History of the Flagellants*; and in 1796 *Strictures on the Union of Scotland with England*.

**Deloney**, THOMAS (circa 1550–1600), silk-weaver, balladist, pamphleteer, and writer of fiction, had produced some of his work by 1586. He has been credited with 'The Blind Beggar of Bednall Green,' and other well-known ballads, printed in the *Garden of Goodwill*. His *Jack of Newbury*, *Thomas of Reading*, and *Gentle Craft*, with their lively dialogue and characterisation, are not far from the later novel. See F. O. Mann's edition of Deloney (1911), and a book by A. Chevalley (Paris, 1926).

**Delorme**, MARION, daughter of an official in Champagne, was born 3d October 1613, and came at an early period of her life to Paris, where her great beauty and brilliant wit soon gathered a group of wealthy and high-born lovers round her. Even the great Cardinal Richelieu was not insensible to her charms, and revenged himself for her contempt by causing her to be separated from the ill-fated young Cinq-Mars, her love for whom was the one ennobling passion of her life. Among her lovers were, in succession, the Duke of Buckingham, Saint-Evremond, the Duc de Brissac, the Chevalier de Grammont, and Emeri, the Superintendent of Finance. During the first disturbances of the *Frondeurs*, her house was the rallying-point of the chiefs of that party, and in consequence Mazarin was about to fling her into prison, when she suddenly died in 1650. A curious tradition sprang up in France during the next century, to the effect that Marion had not died, but escaped to London; that she had married an English lord, had then returned to Paris, and married first a robber-chief, next a procurator of finance, and, finally, that she died in 1706; or, according to another account, even so late as 1741. Her story was treated by Victor Hugo in a drama; by Alfred de Vigny in his romance *Cinq Mars*. See Eugène de Mircourt's imaginative *Confessions de Marion Delorme* (3 vols. 1851).

**Delos** (called also in ancient times *Asteria*, *Ortygia*), an island in the Grecian Archipelago, the smallest of the Cyclades, is situated between the islands Rhenea and Mykonos. According to the mythological account it was at first a floating island, but was fixed to the bottom by Zeus in order that it might become a safe abode to Leto for the birth of Apollo and Artemis. Its earliest historical inhabitants were Ionians, and it appears to have been the centre of a great periodical festival held in honour of Apollo, both on the mainland and in the islands. In 426 B.C. Delos was purified by the Athenians, all the tombs were removed from it, and it was declared pollution for any birth or death to take place on it. Four years after they expelled the Delians from the island. After 146 B.C., when Corinth fell, Delos became the seat of extensive commerce. Its sacred associations, its great festival, its excellent harbour, and its situation in the direct route from southern Europe to the coasts of Asia, all combined to render it a port highly favoured by merchants. So great was the traffic of Delos that it is said 10,000 slaves changed hands here in a single day. After flourishing for a considerable time, it was devastated in the Mithridatic war (87 B.C.), and from this calamity it never recovered. Little more than 1 sq. m. in area, it was noted for its palm-trees, and also for its brass, and the brazen vessels which it manufactured. The town of Delos, which stood at the foot of Mount Cynthus, a granite crag 347 feet high, is a mass of ruins, in which frescoes, mosaic floors, &c. help us to reconstruct its domestic

life. The remains of the great temple of Apollo, and of the colossal statue raised in his honour, may be distinctly traced. Since 1877 extensive investigations have been prosecuted in its ruins by Homolle and other French archaeologists. See Homolle and Holleaux, *Explorations archéologiques de Délos* (Ecole française d'Athènes, 1909 *et seq.*).

**Delphi**, an ancient Greek town in Phocis, celebrated chiefly for its famous oracle of Apollo, was situated about 8 miles N. of an indentation in the northern shore of the Gulf of Corinth, at the southern base of Parnassus. Homer invariably speaks of it as Pytho. It stood in the centre of a district renowned for its classical associations. Occupying the vale of the Pleistos, it was seated in a semicircle like the area of a grand natural theatre, backed towards the north by two lateral spurs of Parnassus. From the cliffs springs the famous fountain of Castalia. The earliest inhabitants of Delphi are said to have come from Lycorea, a town upon one of the slopes of Parnassus, the inhabitants of which are supposed to have been Dorians. From the Delphian nobles were at first taken the chief magistrates and the priests of the temple, while the Pythia or priestess who delivered the oracle, at first always a young maiden, but latterly always a woman not younger than fifty, was usually selected from some family of poor country-people. In the south-west of the temple was a small chamber, under which was led the water of another sacred spring, Cassotis, now dry, whence was said to arise a cold, intoxicating vapour; and the Pythia having breathed this, sat down upon the tripod or three-legged stool, and thence delivered the oracle, which, if not pronounced at first in hexameters, was handed over to a poet, employed for the purpose, who converted it into that form of verse. As the celebrity of the Delphic oracle increased, Delphi became a town of great wealth and importance, famous not only in Hellas, but also among the neighbouring nations. Here the Pythian games were held, and it was one of the two places of meeting of the Amphictyonic Council (q.v.). The fourth temple, though the first built of stone, was destroyed by fire in 548 B.C., and during the succeeding century a fifth was built by the Alcæonidæ, of limestone fronted with Parian marble. This temple was destroyed in the 4th century, perhaps by an earthquake, and that described by Pausanias was then built, and adorned with statuary by Praxias and Androsthenes. In 480 B.C. Xerxes sent a portion of his army to plunder the temple; but as they climbed the rugged path that led to the shrine a peal of thunder broke overhead, and two huge crags tumbling from the heights crushed many of the Persians to death, while their comrades, struck with terror, turned and fled. It was plundered by the Phocians during the Sacred War, and was attacked by the Gauls in 279 B.C., who were said to have been repulsed like the Persians by portents. The splendour of Delphi subsequently excited the rapacity of many conquerors, and suffered severely by their attacks. Nero carried off from it 500 bronze statues; Constantine also removed many of its works of art to his own capital. In the time of Pliny the number of statues in Delphi was not less than 3000, and within the temple for a long time stood a golden statue of Apollo. The site, carefully excavated and explored by French archaeologists since 1892, shows a walled temenos, up which the Sacred Way winds past the foundations of the buildings and monuments seen by Pausanias to the terrace on which are the somewhat scanty remains of the temple of Apollo, and the sanctuary of Apollo's predecessor, Ge. A very well-preserved theatre occupies the north-west corner. The supposed Omphalos, or 'navel of the world,' was dis-

covered in 1915. The treasury of the Athenians has yielded important inscriptions—hymns to Apollo with musical notation.

See A. Mommsen, *Delphika* (1878), Bouché-Leclercq, *Histoire de la Divination dans l'Antiquité* (1880), Frazer, *Pausanias* (1898), Homolle, *Fouilles de Delphes* (1902 et seq.), Farnell, *Cults of the Greek States*, Bourguet, *Les Ruines de Delphes* (1914), T. Dempsey, *Delphic Oracle* (1918), Poulsen, *Delphi* (trans. 1920).

**Delphinapterus.** See BELUGA.

**Delphin Classics**, an edition of the Greek and Roman classics (64 quarto volumes, 1674–1730) prepared by thirty-nine of the best scholars of the time, under the editorship, originally, of Bossuet and Huet, tutors to the dauphin, son of Louis XIV. The title-pages bear the words, 'In usum Serenissimi Delphini,' hence the name. Editions in octavo of particular authors, as Virgil and Horace, were often reprinted in England. The Delphin Classics are now esteemed of little value.

**Delphinidae.** See DOLPHIN.

**Delphinium.** See LARKSPUR.

**Delta** is the alluvial deposit formed at the mouth of a river from the deposition of the particles which it has held in suspension or rolled forward upon its bed. The term was originally applied to the tract of land thus formed (mainly within historical times) by the Nile, which, being inclosed by two main branches and the sea, has the form of the Greek letter Δ, delta. The formation of deltas depends more upon the absence of opposing currents at the mouth of the river than upon the quantity of sediment held in suspension when it reaches the sea. Deltas are consequently of almost invariable occurrence in inland lakes, in the quiet estuaries of the nearly tideless Mediterranean, and in the sheltered bays and gulfs of other seas. When, on the other hand, there are strong ebb-tides, or powerful oceanic currents, the detritus is carried off into the sea.

**Deluc**, JEAN ANDRÉ, geologist and meteorologist, was born at Geneva in 1727. Settling in England in 1773, he was appointed reader to Queen Charlotte, a post which he retained till his death at Windsor, 7th November 1817. He was author of thirteen works.

**Deluge** (from the Latin *diluvium*, 'flood,' through the French). There is a widespread tradition amongst a large number of races that in primitive times the earth was devastated by a great deluge. The best-known embodiments of this tradition are found in (a) the Old Testament story of the flood (Gen. vi. 5–ix. 19); (b) the Babylonian account which exists in two forms—i.e. in the narrative of Berossus and the flood-tablets; (c) the Indian deluge story preserved in the *Satapatha Brahmana* (Muir, *Sanskrit Texts*, i. 196–201); (d) the Zoroastrian myth preserved in the Zend-Avesta (*Vendidad*, ii. 46 ff.); (e) the Phrygian story.

The most important of these records is undoubtedly the Babylonian, especially in the form preserved in the flood-tablets, since it appears to be quite certain that this was the source from which the Genesis narrative was derived. The story is as follows: The gods, at the instigation of Bel, determine to destroy the world owing to its sin. One of the gods, Ea, selects a man named Par-napisti, and warns him of the approaching doom, telling him to build a ship to save his own life and the 'seeds of life of all kinds.' Into this ship, the dimensions of which are specified in the tablets, Par-napisti collects his family, his servants, his cattle, and 'wild beasts of the field.' When they have safely entered the ship, and the door is barred, the deluge begins. All the elemental

forces of nature are unloosed; rain falls in torrents, and the earth is covered with dense darkness. The storm rages incessantly for six days and nights, till the whole land becomes a sea. On the seventh day the rain abates, a calm ensues, and the ship grounds on the top of Mount Nisir. After an interval of seven days Par-napisti sends out one after another—a dove, a swallow, and a raven. The two former return, but the raven never comes back. This is regarded as an indication that the deluge is over. Appropriate sacrifices are offered, and the refugees open the door of the ship, and return to the earth. The remarkable coincidences between the narrative and the story in Genesis are too striking to be merely accidental.

The Genesis narrative itself in its present form is composite in its origin. Part of the story is derived from the Priestly Code (5th century B.C.), and the remainder from the Yahwistic document, 900–750 B.C. (See BIBLICAL CRITICISM, PENTATEUCH.) It is the weaving together of these two documents that accounts for the discrepancies in the story. For instance, in Gen. vi. 19 we read, 'And of every living thing, two of every sort shalt thou bring into the ark;' but in Gen. vii. 2 the injunction runs, 'Of every clean beast thou shalt take to thee seven and seven.' In Gen. vii. 12 the duration of the deluge is given as forty days, but in vii. 24 the statement is made that 'the waters prevailed upon the earth an hundred and fifty days.'

It is no longer possible to accept the account of a primitive universal deluge as historical fact. There are too many difficulties in the supposition that the whole face of the earth was once covered with a flood, and only a few lives were saved by means of an ark. But, on the other hand, it does not seem possible that these stories are altogether the products of the imagination. There are three modern explanations: (1) The flood stories are a nature-myth—portraying the departure of winter, the rainy season, and the return of spring; (2) they are a variant of the creation-myth, and represent not the destruction of a world which was already in existence, but the first emergence of the earth out of the waters (see CREATION); (3) the most probable view is that they perpetuate the tradition of some local disaster—e.g. a great flood, the devastation caused by a tidal wave, the havoc wrought by an earthquake, an abnormal overflow of a river like the Euphrates or the Nile. Professor Prestwich held that the flood was probably on a more extensive scale. He maintained, on geological grounds, that long after the appearance of palæolithic man there was a subsidence of the crust of the earth in western Europe and north-west Africa, and a great inundation of the sea, and that this event might have been the basis of the deluge narrative. The weak point in the theory is that the flood-story does not emanate from the districts indicated. See Prestwich, *On certain Phenomena belonging to the Close of the last Geological Period*; Nöldeke, *Der Mythos von der Sündfluth*; article on 'Flood,' by Woods, in *Hastings's Bible Dictionary*; article by Zimmermann and Cheyne on 'Deluge' in *Encyclopædia Biblica*.

**De Lunatico Inquirendo.** See INSANITY.

**Delundung**, a kind of Civet (q.v.).

**Delusion.** See HALLUCINATIONS, ILLUSIONS.

**Delvino**, a town of Albania, 45 miles WNW. of Janina, with a trade in oil and fruit. Pop. 6000.

**Dem'ades**, an Athenian orator, who, a bitter enemy to Demosthenes, promoted eagerly the Macedonian interest, and was sent away in safety by Philip when taken prisoner at Cheronea (338), but had not the grace to be honest even in his anti-patriotism, and was put to death for his treachery by Antipater in 318.

**Demand and Supply.** In Political Economy demand has reference to the quantity of goods asked for in the market, and supply has reference to the quantity of goods offered. The laws of demand and supply may be thus stated: when the demand exceeds the supply, competition grows stronger among the buyers, and prices rise, and when the demand falls short of the supply, competition grows stronger among the sellers, and prices fall; or thus, falling prices tend to lessen the supply and increase the demand, while rising prices tend to increase the supply and lessen the demand. A rise in prices tends to encourage production, while a fall in prices tends to discourage it. Conversely, consumption is promoted by falling and lessened by rising prices. The result is that demand and supply continually tend to equilibrium. Under such a system it is assumed that buyers and sellers or producers and consumers are free to fix their own prices. In other words, the laws of supply and demand prevail under a system of free competition.

**Demavend,** MOUNT, an extinct volcano of Persia, forming the loftiest peak of the Elburz Chain, which separates the low shores of the Caspian Sea from the high tableland of Persia. The height is about 18,600 feet. It supplies pumice and sulphur. Sulphur vapours still rise from it.

**Dembea,** LAKE. See TZANA.

**Dembinski,** HENRY, a Polish general, was born near Cracow, 16th January 1791, entered the Polish army in 1809, and fought under Napoleon against Russia and at Leipzig. In the Polish revolution of 1830 he so distinguished himself that for a short time he was commander-in-chief of the national army; in 1833 he entered the service of Mehemet Ali. On the outbreak of the Hungarian insurrection, Kossuth appointed him commander-in-chief of the Hungarian army. He drew up a plan of the campaign, but was hampered by the jealousy of Górgéi; and after the defeat of Kopolna (February 26-28, 1849) he was forced to resign his command. At Kossuth's resignation Dembinski fled to Turkey, but in 1850 he returned to France, and died at Paris, 13th June 1864. He was author of *Mémoires* (1833) and four other works.

**Deme** (Gr. *dēmos*), a subdivision of ancient Attica and of modern Greece. The *dēmoi* were townships or hundreds, subdivisions of the *phulai*, and were equivalent to the Dorian *kōmai*, Lat. *pagi*; in the time of Herodotus they were 100 in number (10 in each *phulē*), afterwards 170; their origin was commonly referred to Theseus. The word *dēmos* early came to be applied to the commons, and survives significantly in our *democracy* and *demagogue*.

**Demembré,** or DISMEMBERED, a heraldic term to signify that the members of an animal are cut from its body.

**Dementia.** See INSANITY.

**Demerara,** one of the three counties of British Guiana (q.v.), between the Abari and the Essequibo, takes its name from the Demerara River, which rises in the Maccari Mountains, in about 4° 40' N. lat., and after a northerly course of about 200 miles, enters

the Atlantic at Georgetown. The mouth is 1½ mile wide, but is obstructed by a bar at low tides; the stream is navigable for 90 miles, and has many flourishing settlements on its banks.

**Demesne** was that portion of the lands of a Manor (q.v.) which the lord of the manor reserved for his immediate use and occupation.

**Demeter,** the Ceres of the Romans, was one of the chief divinities of the Greeks. She was the earth-goddess, the patroness of agriculture and of fruits, and her name itself most probably meant Mother-Earth (*gē-mētēr*). She was the daughter of Cronus and Rhea, and was by Zeus the mother of Persephone (Proserpine), who was carried off while gathering flowers in the Nysian plain, in Asia, by Aidoneus (Pluto), the god of the nether world. Demeter wandered for some time in search of her daughter, and when she learned whither she had been carried, quitted Olympus in anger, and dwelt on earth among men, as at Eleusis, bringing blessings in her train. At length Zeus sent Hermes to bring back Persephone, and both mother and daughter then returned to Olympus, whereupon the earth again brought forth her fruits. As Persephone had eaten a part of a pomegranate in the under world, she was obliged to spend one-third of the year in the gloomy kingdom of her husband, returning to her mother the remainder of the year. Many later additions were made to this beautiful story, in which it is not difficult to see an allegorisation of the burial and revival of the seed-corn within the ground. The Latin poets made Enna, in Sicily, the scene of Proserpine's rape. The Eleusinia were held every year at Athens, in honour of Demeter and her daughter, as well as the Thesmophoria, both there and in other parts of Greece. The Athenians revered her especially as the originator of civilised life and its arts, which all rest on the basis of agriculture. In art Demeter is represented fully clothed, a garland of corn-ears round her head, in her hand a sceptre, corn-ears, or a poppy, and sometimes with a torch and mystic basket. The worship of Demeter, known as Ceres, reached Rome from Sicily, and ultimately acquired great political importance. Her chief festival there was the Cerealia. See CERES.

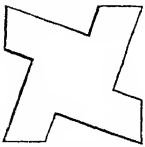

**Demetrius,** or DMITRI. See RUSSIA.

**Demetrius Phalereus,** so named from the Attic demos of Phalerus, a seaport of Athens, where he was born about 345 B.C., was distinguished as an orator and politician. Though descended from a family of neither rank nor property, by his abilities and energy he rose to the highest honours at Athens. He was educated along with Menander in the school of Theophrastus, entered upon public life about 325, and soon made himself famous by his oratory. In 317 he was intrusted by Cassander with the government of Athens, and discharged its duties for ten years with such general satisfaction that the grateful Athenians heaped all kinds of honours upon him, and erected no fewer than 360 statues to his honour. During the later period of his administration he seems to have given himself up to dissipation; and when Demetrius Poliorcetes, Cassander's enemy, approached Athens with a besieging army in 307, Demetrius, having lost the sympathies and co-operation of the Athenians, was obliged to flee. All his statues were demolished except one. He retired first to Thebes, but afterwards found refuge in the court of Ptolemy Lagi, at Alexandria, where he lived for many years, devoting himself to literary pursuits. On the death of his protector, Demetrius was expelled from the court of Egypt, retreated to Busiris in Upper Egypt, and died there from the bite of an asp in 283. Demetrius was the last of the Attic orators worthy of the name. His style was graceful, insinuating, and elegant; bearing, however, in its luxuriousness and tendency to effeminacy, the marks of a declining oratory. The list of his works (fifty in number) given by Diogenes Laërtius shows him to have been a man of most extensive acquirements.

Dismembered.

**Demi-bastion**, in Fortification, differs from a Bastion (q.v.) in having only one flank instead of two and no curtain.

Demi-bastion.

**Demidoff**, a Russian family distinguished for wealth and beneficence, descended from Nikita Demidoff, originally a blacksmith at Tula, who in the time of Peter the Great became famous as a manufacturer of arms, and amassed an immense fortune.

Of the numerous princes of the line, perhaps the most famous is Prince Anatol (1813-70), born at Moscow, but educated in France. He was always remarkable for his enthusiasm in letters and in the sciences; his principal work being his *Travels in South-east Europe* (4 vols. Paris, 1839-40). It contains very valuable scientific observations, and is magnificently illustrated.

**Demi-lion**, **DEMI-ROSE**, **DEMI-FLEUR DE LIS**, &c., in Heraldry, means, when an animal is spoken of, the upper half; and with an inanimate object, the dexter half parted per pale.

**Demi-lune**, in Fortification, is the name formerly given to the work now called a ravelin. See FORTIFICATION.

**Demi-monde** (Fr. *demi*, 'half,' and *monde*, 'world,' or 'society'), a term that came into vogue from the title of a play by the younger Dumas (1855), as applied to a class of women in large towns, and especially Paris, whose disregard for the proprieties prevents their being more than half recognised by society. The word covers women of all degrees of disrespectability, provided only they respect the elegancies of life.—*Demi-rep* is a similar 18th-century word, compounded clumsily enough, for a woman of more than doubtful reputation.

**Demir-Hissar** ('iron-castle'), a town of Greek Macedonia, on a tributary of the Struma, 45 miles N.E. of Salonika; pop. 8000.

**Demise**. See LEASE.

**Demisemiquaver**, half a semiquaver, or the 32d part of a semibreve. See MUSIC.

**Demiurge** (from Gr. *demos*, 'people,' and *ergon*, 'a work,' hence a 'handicraftsman') was the name given in the cosmogony of the Gnostics to the creator or former of the world of sense. He was conceived as the archon or chief of the lowest order of the spirits or sons of the pleroma; mingling with chaos, he formed in it a corporeal animated world. He created man, but could impart to him only his own weak principle, the *psychē* or sensuous soul; therefore the highest, the really good God, added the divine rational soul, or *pneuma*. But the power of evil in the material body, and the hostile influence of the merely sensuous demiurge, prevented the development of that higher element. The demiurge holding himself to be the highest God, could not bring his creatures to the knowledge of the true Godhead; as the Jehovah of the Jews, he gave them the imperfect law of Moses, which promised merely a sensuous happiness, and even that not attainable; and against the spirits of the *hylē*, or world of matter, he sent only a psychical, and therefore powerless Messiah, the man Jesus. See Gnosticism.

**Demmin**, an ancient town of Prussia, on the Peene, which is navigable for small vessels to this point, 29 miles S. of Stralsund by rail. It has manufactures of machinery, bells, ironwares, sugar, lime, and bricks, and a trade in grain, wool, coal, and iron. Pop. 13,000.

**Democracy** ('rule of the people,' from Gr. *demos*, 'the people,' and *kratō*, 'I rule') is a form of government in which power rests with the body of

the citizens. It is opposed to monarchy, the rule of one; to aristocracy, the rule of the 'best' or nobles; and to oligarchy, the rule of the few. It is government of the people by the people, and for the people, as opposed to government by a single chief or a dominant class.

Democracy was a great force in the ancient world, but as then prevalent it had certain characteristics, which very clearly distinguish it from its modern forms. In antiquity the democracy was associated with the city. There was no system of representation by which the people spread over extensive territories could send deputies to speak and act for them in a common parliament. In the ancient democracies, the people were, in the original sense of the word, citizens, who personally appeared and spoke and voted in the assemblies. Another great feature in the ancient world was the existence of a great number of slaves who had no political and few civil rights—i.e. a very large and important part of the population were not reckoned among the citizens at all. Hence it will be seen that the 'people' in the ancient democracy was limited in number, consisting of a city population, and excluding the labouring class or slaves. Thus constituted, the ancient democracy had a most interesting history. It attained to its highest and finest development in the Athens of Pericles before the outbreak of the Peloponnesian war. Besides being a conflict for the headship of Greece between Athens and Sparta, that war was a struggle for supremacy in the Hellenic world between the democratic and aristocratic principles, of which these cities were respectively the representatives and champions. It resulted in the overthrow of the Athenian democracy, but the struggle of the people against the rich and privileged classes continued in the Greek cities as long as they retained their independence. At Rome, too, the history of the city is to a large degree the record of popular struggle against the privileged and wealthy classes. Quiescent for about two hundred years after the reforms of the 4th century B.C., it broke out afresh at the time of the Gracchi, and ended with the triumph of a great chief of the democracy, Julius Cæsar. But this triumph meant the end of the republic, and the permanent rule of a single head, as consolidated under Augustus.

Among the Germanic tribes which overthrew the Roman empire, as among most peoples at a similar stage of development, the general body of freemen had considerable power. But the term democracy properly refers to communities in a comparatively advanced state of political evolution, and it would be an anachronism to apply the theories and problems connected with the word to nations still in the tribal stage.

With the growth of the republics of medieval Italy, and of the cities of Flanders and Germany, began a democratic movement similar in some respects to that of ancient times. It was similar, inasmuch as it was associated with city life, but it differed from the ancient democracy, in so far as slavery ceased to be an important factor, and the development of the medieval cities was controlled or affected by the great feudal states which had now risen. As the great modern states have become consolidated, the cities which played so important a part in medieval life have been absorbed in them. The process has been a slow one, for Venice was an independent republic till the close of the 18th century. Hamburg was fully incorporated in the German empire only in 1888. In the city life which thus came to a close, the struggle between rich and poor, between privileged classes and the people, was more or less present.

The modern democracy differs essentially from the ancient and medieval forms. The people no

longer consist merely of a body of burgesses limited in number, but of millions of men inhabiting extensive countries. A government on such a basis is rendered possible through the representative system, by which the vast electorate choose a convenient number of deputies, on whom the legislative and other functions are conferred. Another important point of difference is the abolition of slavery, serfdom, and the other unfree conditions which formerly prevailed. Freedom of conscience, freedom in the choice of one's residence and profession, have been more or less fully realised. We must also note the progress towards the abolition of all privileged classes, and towards equality before the law.

The modern democracy, as we now see it, is the result of a gradual process of development continued through centuries amidst the severest struggles. Such struggle will appear to be inevitable, when we consider that democracies have grown up in large states in which absolutism formerly prevailed, and in which the military system prevails even yet. Among the decisive steps in the modern struggle of the people against the old classes and systems should be noted the long contest of the Dutch against Spain, the great English revolutions of 1642 and 1688, the war of American Independence in 1776, the great French Revolution of 1789, and the revolutionary periods of 1830, 1848, and 1906-20. The English revolutions of 1642 and 1688 established parliamentary rule in England, though on a narrow basis. Yet they had the important result of proving the *fitness* of a new type of government, which further became a model for similar institutions in other countries. The greatest event in the evolution of democracy till our own times was the French Revolution of 1789; though it failed for the time, it shook the old system to its foundations; it everywhere spread new ideas, and raised questions that could not again be set aside. The revolution of 1830 showed that the reactionary conditions prevalent after Waterloo had no claim to permanency. The revolutionary movements of 1848, which affected France, Italy, Austria, and Germany, were apparently a failure, yet they overthrew what remained of the Feudal system in western and central Europe. But the most significant thing connected with that period is the fact that only a few years afterwards governments which had been most active in suppressing the revolution found it expedient to adopt its cardinal principles. Consciousness of discrimination between the sexes and the economic dependence of the 'wage-slave' under the industrial system came later to have more weight; and in the revolutions of 1917-18 the miseries of war were a precipitating influence.

To England has been given the great historic mission of working out the methods on which the democracy has so far been realised. Her parliament, first constituted under Simon de Montfort and Edward I. in the 13th century, was, as we have seen, firmly established by the long contest with the Stuarts. After many centuries of experience, trial, and struggle, the English parliament became the mother of parliaments. England has not been the first, however, to bring democratic institutions to their fuller development. The Reform Bill of 1832 conferred the franchise on the middle classes; but it was not till the reforms of 1867 and 1885 that she approximated to universal male suffrage, which the act of 1918 left still unachieved. In the emancipation of women Britain lagged behind New Zealand, Australia, Scandinavia, Finland, and some American states. The British government is now substantially a democracy, modified so far by older forms, the monarchy and the House of Lords, plural voting, and economic inequalities. In many countries which adopted

parliamentary institutions, the power of the people was for long much more seriously curtailed; as in Germany, till 1918, by a sovereign claiming to be of divine right. The German emperor may be regarded as having wielded a power co-ordinate with that of the people, and resting on the army. The position of his chancellor did not depend on a parliamentary majority—he was the servant of the emperor; yet he found it expedient to have one.

As we have seen, the distinctive features of the modern democracy are the widest *personal freedom*, by which each man has the liberty and responsibility of shaping his own career; *equality* before the law; and political power in the form of universal suffrage, exercised through the representative system. With these have been associated universal education, and on the continent of Europe universal liability to military service. On the European continent it was imposed upon its peoples by the necessities of the struggle for existence, which the moral development of mankind has not yet been able so to regulate as to put an end to war. Anglo-Saxon countries have happily, except during the Great War, been in practice free from such necessities, whatever they may have been in theory. See CONSCRIPTION.

It is important to remember that the growth of the modern democracy has gone hand in hand with the general development of the most advanced nations of the world. The consolidation of the political power of the people is the result of far-reaching causes operating on a great scale throughout the history of modern nations. The growth of the democracy is intimately connected with the growth of every other factor in the social life. For example, the different stages in the rise of the democracy could be paralleled by the improvements in the art of printing. The development of the democracy has on the one hand created the demand for cheap literature and cheap newspapers, but it has also on the other hand depended on the supply of them. Further, the growth of the cheap newspaper and of cheap literature depends on the industrial development, on the improvement of our technical capacities and resources, on man's growing mastery over nature. To the production of the daily newspaper a thousand technical appliances are subsidiary. Steam and electricity are the great forces that move the vast mechanism on which society is now based. In fact the growth of the democracy is intimately connected with an industrial and technical development which has culminated in the railway, cheap postage, the electric telegraph, and the printing-press. The peculiar influence of the human voice has not been superseded, yet it is chiefly through the telegraph and the printing-press that the modern democracy obtains the education which the ancient democracies received in their popular assemblies and in the daily intercourse of the market-place.

Thus it will be seen that the democracy as we now have it is an outcome of the general historic movement of modern times, and that it is a fact which is not yet accomplished, but is still in process of making. What its ultimate results for good or evil may be, no man can predict. Scarcely any one, however, will deny that it has greatly raised the average level of intelligence and morality in modern nations. The life of the citizen from the day he enters the elementary school is a continual process of education, and it brings with it in abundant measure the discipline of responsibility. It carries with it also the safeguard of publicity. The public interests are protected by incessant watchfulness and public criticism. On the other hand, the drawbacks of democratic government are obvious enough. Such vast masses of electors are too much controlled by governments, caucuses, newspapers,

and special interests; real interests are concealed under party watchwords, and sacrificed to them. Popular passions are liable to upset the plans of experienced policy, and the demagogue or the newspaper boss too often ousts the true statesman. It may be added that in the administration of foreign affairs, the changefulness and publicity usually characteristic of the democracy place it at a disadvantage against the secrecy, continuity, and tenacity of a government like that of Russia in the days of the autocracy.

Much has been written on the merits and demerits, the advantages and disadvantages of the democracy. It really perhaps concerns us more to observe the fact that it is the inevitable outcome of the prevalent historic forces, that it has a great function in modern history, and that it is the duty of the citizen and statesman to do their duty under it, and to adapt it to the material, intellectual, and moral improvement of men.

See the articles GOVERNMENT, REPRESENTATION, SOCIALISM, WOMEN'S RIGHTS; De Tocqueville, *Democracy in America* (1832); Motley, *Historic Progress of American Democracy* (1869); Freeman, *Comparative Politics* (1873); Sir T. E. May, *Democracy in Europe* (1878); Sir H. S. Maine, *Popular Government* (1885); and books by Sir T. E. May (1878), Lecky, Lowell, Webb, Adams, Hobhouse, Ostrogorski, Bryce, Ramsay Macdonald.

**Democrats**, one of the names for a party in the United States, also called Republicans, who, as early as Washington's first administration, sought to limit the federal power, and to increase that of the states and of the people. About 1808 the title of Republicans as synonymous with Democrats disappeared. See REPUBLICANS. Electing Jefferson president in 1801, the Democrats remained in power till 1841, and the administration was in their hands also in 1845-49, in 1853-61, in 1885-89, in 1893-97, and in 1913-21. Democratic presidents have been Jefferson, Madison, Monroe, John Quincy Adams, Jackson, Van Buren, Polk, Pierce, Buchanan, Cleveland, Woodrow Wilson. For the history and principles of the Democratic party, including latterly the reform of the tariff, see UNITED STATES.

**Democritus**, an illustrious Greek philosopher, was born at Abdera, in Thrace, about 470 or 460 B.C. Of his life little is known. The statement that he was first inspired with a desire for philosophic knowledge by certain Magi and Chaldeans whom Xerxes had left at Abdera, on his Grecian expedition, is as untrustworthy as that which represents him as continually laughing at the follies of mankind. His extensive travels, however, through a great portion of the East, prove the reality of this desire, as does also his ceaseless industry in collecting the works of other philosophers. Democritus was by far the most learned thinker of his age. He had also a high reputation for moral worth. He appears to have left a strong impression of his disinterestedness, modesty, and simplicity on the mind of the community, for even Timon the scoffer, who spared no one else, praised him. The period of his death is uncertain. He lived, however, to a great age. Only a few fragments of his numerous physical, mathematical, ethical, and musical works are extant. These have been collected by Mullach (Berlin, 1843). Cicero praises his style, and Pyrrhon imitated it.

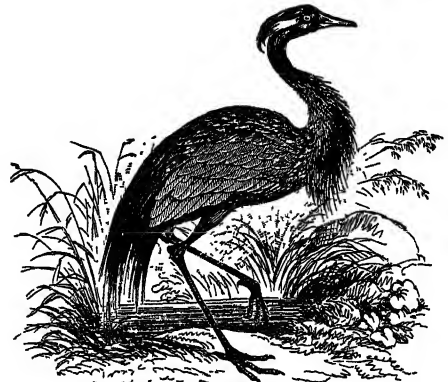

Democritus's system of philosophy is known as the *atomic system*, which is considered to have been founded by Leucippus. Its essence consists in the attempt to explain the different phenomena of nature—not like the earlier Ionic philosophers, by maintaining that the original characteristics of matter were *qualitative*, but that they were *quantitative*. He assumes, therefore, as the ultimate elementary ground of nature, an infinite

multitude of indivisible corporeal particles, *atoms* (see ATOM), and attributes to these a primary motion derived from no higher principle. This motion brings the atoms into contact with each other, and from the multitudinous combinations that they form, springs that vast and varying aggregate called *nature*, which is presented to our eyes. Democritus did not acknowledge the presence of *design* in nature, but he admitted that of *law*. 'The word *chance*,' he says, 'is only an expression of human ignorance.' He believed strictly in secondary or physical causes, but not in a primary immaterial cause. Life, consciousness, thought, were, according to him, derived from the finest atoms; those images of the sensuous phenomena surrounding us, which we call mental representations, were, according to him, only material impressions, caused by the more delicate atoms streaming through the pores of our organs. Democritus boldly applied his theory to the gods themselves, whom he affirmed to be aggregates of atoms, only mightier and more powerful than men. His ethical system, spite of the grossness of his metaphysics, is both pure and noble. Such fragments of his writings as we possess contain beautiful, vigorous, and true thoughts concerning veracity, justice, law, order, and the duties of rulers; while, in a spirit not alien to Christianity, he looks upon an inward peace of heart and conscience as the highest good. Epicurus (q.v.) and Lucretius (q.v.) developed his system.

**Demodex.** See ACARUS.

**Demogot**, JACQUES CLAUDE, a French *littérateur*, born 5th July 1808 at Paris, lectured at Beauvais, Rennes, Bordeaux, and Lyons, became in 1843 professor at the Lycée St Louis, and afterwards at the Sorbonne. Most of his books treat of the history of literature; the chief are *Les Lettres et les Hommes de Lettres au XIX<sup>e</sup> Siècle* (1856); *Histoire de la Littérature française* (1857), an admirable hand-book; *Tableau de la Littérature française au XVII<sup>e</sup> Siècle* (1859); and *Histoire des Littératures étrangères* (2 vols. 1880). His poems are little known. He died 9th January 1894.

**Demoiselle** (*Anthropoides*), a genus of birds in the crane family (Gruidæ), differing from the true cranes in having the head and neck quite feathered, and the beak no longer than the head. The Demoiselle (*A. virgo*) is about 3 feet in length

Demoiselle (*Anthropoides virgo*).

from the point of the bill to the tip of the tail, and the top of its head is about  $3\frac{1}{2}$  feet from the ground. It is remarkable, like its relatives, for elegance and symmetry of form, and grace of deportment. The feathers covering the upper part of the wing are much elongated, as in the cranes. The general

colour of its plumage is gray, but the sides of the head are adorned with two elegant white tufts, and the breast bears long blackish feathers. The demoiselle is an African and Asiatic bird, but visits Greece and other parts of the south of Europe. To the same genus belongs the beautiful Stanley Crane (*A. paradisaus*), a larger and taller bird found in the East Indies.

**Demoivre**, ABRAHAM, a distinguished mathematician, was born at Vitry, in Champagne, 26th May 1667. A Protestant, he fled to England in 1688, after the revocation of the Edict of Nantes, and there long supported himself by private tuition and public lecturing. The appearance of Newton's *Principia* incited him to increased devotion to mathematical studies, and at last he ranked among the leading mathematicians of his time. He was a member of the Royal Society of London, and of the Academies of Berlin and Paris. The *Philosophical Transactions* of London are enriched by many contributions from his pen; and he was so esteemed by the Royal Society that they judged him a fit person to assist in the decision of the famous contest between Newton and Leibniz for the merit of the invention of fluxions. He died in London, 27th November 1754. Among his published works are *Annuities upon Lives* (1725), *Miscellaneous Analytica de Seribus et Quadraturis* (1730); and *The Doctrine of Chances* (1718 and 1738), dedicated to Sir Isaac Newton. Demoivre's name is well known from its association with a useful trigonometrical formula—viz. that, where  $k$  is any real quantity,  $\cos k\theta + i\sin k\theta$  is always one value of  $(\cos \theta + i\sin \theta)^k$ .

**Demonetisation.** See BIMETALLISM.

**Demonology**, the doctrine that relates to demons, a body of spiritual beings inferior in rank to deities proper, but yet capable of influencing human affairs. The earlier and more widely-spread conception of the demon was merely that of a more or less powerful and intermediate agent between gods and men, at one time resolving himself into a kind of special guardian or patron-spirit, at another acting as the minister of the divine displeasure. The gradual differentiation between the beneficent and the malignant qualities of demons resulted in the division into good spirits or guardian-angels and evil spirits or devils; and Christian theology, developing earlier Jewish ideas—themselves powerfully modified by the influence of Persian dualism—worked up the one class into an elaborate hierarchy of angels and arch-angels, the other into a formidable host of fallen angels or devils, considered as continually employed in frustrating the good purposes of God, and marshalled under one master-spirit, the devil proper or Satan, the supreme impersonation of the spirit of evil. The guardian-angel corresponds closely to such conceptions as the Roman *genius* and even the famous *daimon* of Socrates. To primitive man the demon was but one of the thousand spiritual beings who controlled every one of the causes of nature, and whose favour must be purchased by constant tributes of respect and worship. It was perfectly consistent with primitive philosophy that the manes or ghosts of the dead should continue after death the influence they enjoyed in life, and thus should pass into the higher class of deities. The essential distinctions between the divine and the human that seem so fundamental to modern minds did not occur to those whose notions of the visible and invisible universe alike were entirely animistic; and thus we find that the savage makes no clear distinction between ghosts and demons, and that his conception of the demon is constructed on the model of the human soul, of course with any number of terrible and superhuman qualities

superinduced. It is not merely family affection, but actual fear and considerations of prudence, that lead to the worship of ancestors and of the dead; and the good or bad fortune of living men is attributed to the direct interference of the invisible spirits with which the whole air around is swarming. These spirits may not only affect the fortune of the individual, but may even enter into his body, and cause internal diseases and such other inexplicable phenomena as frenzy, wild ravings, hysterical epilepsy, and the like. The very etymology of such words as *cataplexy* and *ecstasy* points plainly to a time when there was no metaphor in their meaning. Such is the explanation of disease offered at the present day by savage man all over the world, and such was also the belief of the semi-civilised ancient Egyptians and Babylonians. Indeed, it disappeared but slowly before the progress of scientific medicine, and continued to reappear in survivals strangely perplexing on any other explanation. Hence the function of the exorcist arises naturally as a means of effecting a cure by expelling the demon, and we find him daily exercising his skill in Africa, and even in China and India. A careful distinction is made by sorcerers as to whether the infesting demon *possesses* or *obsesses* his victim—i.e. controls him from the inside or the outside. In early Christian times those demoniacally possessed, or *energumens*, were grouped into a class under the care of a special order of clerical exorcists, and after the time of St Augustine the rite of exorcism came to be applied to all infants before baptism. Indeed, exorcists still form one of the 'minor orders' of the Catholic Church.

Reverting to the animistic theory of demonology, we find how well it harmonises with widely-spread notions in folklore of phantom-dreams—night-mare (O.E. *mare*, 'a goblin'); the Slavonic vampires, or witch-ghosts, who suck the blood of living victims; *incubi* and *succubæ*, like Adam's wife Lilith in the rabbinical story (Assyrian *lilit*, 'a succuba'), demons who consort with women and men in their sleep and by whose means children may be engendered between demons and women; the Hindu *rakshas*, malignant and gigantic demoniacal ogres who can at will assume any shape; and witches, who have confessed a thousand times to being possessed with a familiar spirit, and who own allegiance in particular to the master-demon, Satan. Other embodiments of the spirit of evil are the Celtic and Teutonic Giants, and the Ogres of southern romance, who destroy men and devour their flesh; the Norse Trolls, one-eyed, malignant but stupid monsters; the *Diakos* and *Lamias* of modern Greece; the Lithuanian *Laume*; the Russian fiery and flying snakes, *Koshchei* the Deathless, *Baba Yaga*, a hideous old hag who flies through the air in a fiery mortar, propelled with a pestle, and the *Morskoi Tsar*, or king of the waters, with his daughters, the ubiquitous swan-maidens of romance. No mythology is richer than the Slavonic in malignant male and female demons and fiends (*chorti*, 'devils'), gloomy shadows of old nature myths and degraded forms of the great deities of an earlier religion, a combination of the most heterogeneous elements flung together in the most perplexing confusion. Traces remain of an original dualism between a great black and a white god (*Byelun*); but besides this and those fiendish forms already mentioned, Ralston enumerates the *karliki*, or fiendish dwarfs; *lyeshuie*, sylvan demons resembling the fauns and satyrs of Greek mythology; *vodyanue*, or water-sprites; *vodzhrushnie*, demons who ride the whirlwinds; *demovue*, or domestic spirits like the Scottish *brownies* and the Lithuanian *kaukas*; and the *rusalka*, a kind of Naiad or Undine.

Demons with specialised functions exist in mythology everywhere, as the Japanese Oni, who bring on winds, themselves living at the centre of the storm; the Chinese air-dragons, whose battles bring on waterspouts; the demons of floods in old Egyptian and Akkadian mythology; the spectres and phantoms that infest the sea; the nixies of northern Europe, and the kelpies of Scotland, who haunt pools to drown unwary travellers, and naturally hate bridges, although elsewhere many bridges as well as other superhuman works have been erected, usually in miraculously short periods of time, by demons, often at the command of powerful magicians like Michael Scott. Sometimes the devil even consents to build a church for the reward of the soul of the first that enters it. Others again are those sirens who, by their unearthly beauty or the charm of their singing, draw on unwary youths to their ruin; most famous of these, the romantic Lorelei of the Rhine. Again, particular animals, chiefly those with power to harm man, are favourite hosts for demons to inhabit, especially the serpent, but also the cat, the hedgehog, the hare, the fox, the he-goat, the raven, the wolf—the old Norse Fenris, and the dog, especially if black in colour, like the dog in *Faust*. The madness of dogs, with its peculiar horror, itself opens up a strange chapter in the history of demonology.

One of the most systematic of demonologies is that elaborated by the Moslem theologians. The Jinn (sing. Jinnee) were created two thousand years before Adam, but sinned against God and were degraded from their original high estate. The greatest among them was Iblees (Eblis), who was cast out by Allah for refusing to worship Adam as made of earth, he himself having been formed of smokeless fire. The Shēytāns form his host; other species of subordinate fiends are the Jānn, the least powerful, also 'Efreetis (Afrits) and Mārīds, the last the most powerful. Eminent among the evil Jinn are the five sons of Iblees—Teer, who brings about calamities, losses, and injuries; El-Aawar, who encourages debauchery; Sót, who suggests lies; Dásim, who causes hatred between man and wife; and Zelemboor, who presides over places of traffic. Inferior demons are the Ghoul, often in human form and devouring the bodies of the dead like the Russian werewolves; the Sealh, found in forests; the Delhān, living in islands; and the Shikk, shaped like a human being halved lengthwise. The Jinn assume various shapes, sometimes as men of enormous size and portentous hideousness. They live chiefly on the mountains of Káf, which encompass the whole earth, and their evil influence may be averted by talismans and invocations, and pre-eminently wise magicians like Solomon may command their services. They consist of forty troops, each troop containing six hundred thousand. See chapter ii. of Lane's *Arabian Society in the Middle Ages* (edited by Stanley Lane-Poole, 1883).

The subject of dualism, or the division of all the invisible powers into two great armies of good and evil demons, ranged under the supreme impersonations of good and evil, will be discussed under ZOROASTER, and here it is sufficient to say that it modified the whole later Jewish and Talmudic demonology, and reappeared in the Manichæan heresy. To it is due the distinction between the *demon* and the *devil*, a notion which seems fundamental to the modern moral sense, but was foreign to the earlier demonology, according to which all the specially malignant qualities and the love of evil for its own sake become characteristic of the latter. The Vritra and the other night-powers, the Panis, of the Vedic hymns, are as yet hardly more than personifications of merely physical evil, not inherently and absolutely wicked; while the

Loki of the ancient Scandinavians, their nearest approximation to a personification of evil, was rather a demigod than a devil, not essentially hostile to the other deities, although he works them mischief enough; and the four archdemons of the Rabbins, Samaël, Azazel, Asael, and Mac-cathiel, seem to have been originally nothing more than personifications of the elements as energies of the deity. Even the name Lucifer ('the light-bearer'), the fallen angel of the morning star, fits ill with a conception of a devil utterly and hopelessly evil. The widely-spread belief that demons are lame accords well with a supposed fall from heaven and an original state of innocence. It is not a little striking at any rate to find the same characteristic in Hephaistos, Wayland the Smith, and the Persian Aśhma—the Asmodeus of the Book of Tobit, the 'Diable Boiteux' of Le Sage. The sootiness of his abode and his blackness of colour are persistent characteristics, although, indeed, some West African negroes have a white devil. The usual cloven feet of the devil in European folk-tales, often the last mark of identification, when even the horns and the tail are hidden, is a reminiscence of the Greek satyr and the forest-sprites of old Teutonic and other folklore. The ugliness of the medieval representations of the devil in religious art, as may be seen in the fantastic gargoyles of many churches, was but a part of the early church's policy of degradation to which the native deities were subjected, and from which sprung the medieval belief that the various gods of the old heathen world were the devils or degraded angels of Scripture. This notion is familiar to readers of *Paradise Lost*, although Milton makes an ingenious poetic use of it that is all his own. And even the medieval devil, with all his terror, had strange limitations to his power, especially perhaps in the folklore of the north. He is often ludicrously outwitted, and his machinations foiled by some obvious enough device or verbal quibble. It is not merely the weakest saint upon his knees that can baffle his infernal schemes, but some country-fellow who beats him at his own weapons, and whom afterwards he will have in hell at no price. The old Scots notion of Satan as grown so much the more dangerous from the accumulated wickedness and wisdom of six thousand years is hopelessly inconsistent with the archfiend of Norse folklore.

The early Christian idea of hell, the abode of the demons, owed many of its features to the Jewish Gehenna, with its perpetual fire, the horror of its sacrifices, and its loathsome worm; and the characteristics of Moloch and other primitive fire-gods became associated with the devil, degraded from a fire-god to a mere powerful spirit. The Jinn of Arabian mythology, who are slaves of the lamp and ascend as clouds of smoke, serve also to show how fundamental was the notion of a fire-fiend which passed, though under degraded form, into Christian theology. Consistent with this is the widespread belief in Europe that the devil cannot touch or cross running water, of which poetic use is admirably made in the magnificent phantasy of *Tam o' Shanter*. Again, the struggle between Balder and the deadly powers of winter in the Norse mythology was spiritualised and amplified into Christ conquering Death and Hell and releasing the spirits from prison; and the old northern ideas of wintry cold personified into a powerful and malignant demon, under new influences passed to swell the attributes of the Christian devil, whose dreary abode provided those torments of frost as well as fire familiar to readers of Dante. No stories are more common than those of compacts with the devil, sometimes written in blood, by

which a man gave away his soul for wisdom, wealth, power, or other gratifications to be enjoyed for a certain number of years. The classical story in this kind is that of Faust, which the genius of Goethe has made an imperishable part of the intellectual birthright of Europe.

Raising the devil or his inferior demons was a feat within the power of the mediæval sojceers and masters of the black art, and elaborate formulas for the purpose are gravely given in the books of magic. This unholy art was made punishable by death by James I., and his law remained upon the statute-book of England till the reign of George II. The worship of the devil was a usual feature of the witches' sabbath, and the name is often applied still to the strange dances and other religious rites by which many tribes in India and elsewhere avert the anger of malignant deities. It must be understood that there is no conscious homage to the principle of evil as opposed to good, as the objects of worship are merely deities powerful for harm as well as for help, considered almost as entirely outside any moral considerations, like the demons of unmixed primitive religion everywhere.

See the articles ANGEL, ANIMISM, DEVIL, EVIL, EXORCISM, HELL, SERPENT-WORSHIP, WERWOLF, WITCHCRAFT, ZOROASTER; also Horst, *Dæmonomagic* (2 vols. 1818), and *Zauberbibliothek* (6 vols. 1821-26); Ukert, *Ueber Dämonen, Heroen, und Götzen* (1850); Bastian, *Der Mensch in der Geschichte* (3 vols. 1880); Tylor, *Primitive Culture*; Roskoff's admirably learned *Geschichte des Teufels* (2 vols. 1869); Frazer, *The Golden Bough*; *The Encyclopedia of Religion and Ethics*; and for its facts, Mounire D. Conway's *Demonology and Devil-lore* (2 vols. 1879); also some of the older books, as Bodin, *De Magorum Demonumina* (1581), and the like.

**De Morgan**, AUGUSTUS (1806-71), son of Colonel De Morgan of the Indian army, was born in Madura, Madras Presidency. Educated at several private schools, he 'read algebra like a novel' (novels themselves he devoured insatiably); but after four years at Trinity College, Cambridge, he graduated as only fourth wrangler (1827). As a result of his revolt from his early evangelical training he did not take orders. He was appointed first professor of Mathematics in University College, London, after its foundation in 1828. In 1831 he resigned this office, but was reappointed in 1836, and continued in that capacity till 1866. An energetic worker, he was secretary of the Astronomical Society (1831-38 and 1848-54), and held other offices therein. His writings are very numerous. Besides being a mathematician of the first order, he was extensively and minutely versed in the history of the mathematical and physical sciences. He also devoted himself to the development of Aristotelian or 'Formal' Logic, to which he gave so symbolical a shape as to make it seem like a branch of Algebra (see *Formal Logic*, 1847; ed. Prof. A. E. Taylor, 1926), and wrote on the calculation of insurances and on decimal coinage. His best-known work is his *Budget of Paradoxes* (1872; new ed. 1915) reprinted from the *Athenæum*. See the Life by his wife (1882). His son, WILLIAM FREND (1839-1917), born in London, studied art, and specialised in stained glass and, ultimately, ceramics. Not till 1905, when sixty-six, did he take to literature. His first novel, *Joseph Vance: An Ill-Written Autobiography* (1906), with its suggestion of Dickens and the Victorians, seemed to have strayed from the 19th into the 20th century. *It Never can Happen Again* and a dozen other stories followed, but none equalled *Joseph Vance* in solid merit and popularity. See A. M. W. Stirling, *William de Morgan and his Wife* (1922).

**Demosthenes**, an able Athenian general, who in 425 B.C. assisted Cleon to reduce Sphacteria,

and who in 413, being sent to Sicily to the relief of Nicias, fell, fighting bravely, into the hands of the Syracusans, and was put to death.

**Demosthenes**, the greatest orator of Athens and of Greece, was born about 383 B.C. He lost his father at an early age. The considerable inheritance bequeathed to him was reduced by the neglect or the fraud of his guardians, and when he came of age he proceeded to prosecute them. The litigation was long and complicated, and though he gained verdicts in his favour, most of his inheritance was irretrievably lost. The importance of this litigation was that it compelled Demosthenes to the study of the law, gave the first exercise to that doggedness and strength of will which was to mark him through life, and by reducing him to poverty, drove him to the pursuit of law as a means of living. At Athens the parties to a suit were compelled to plead their cause themselves, but they could not be prevented from getting their speeches composed for them by a professional 'speech-writer' or 'logographer.' Demosthenes became a logographer, and soon acquired a lucrative practice. Up to the age of thirty Demosthenes confined himself to 'speech-writing,' and gained considerable reputation as a constitutional lawyer. His most famous constitutional law speech is one which he delivered personally in support of Ctesippus against Leptines (354 B.C.). He seems to have lacked by nature all the physical qualifications of a great orator, and to have acquired them solely by indefatigable self-discipline and training. At about the age of thirty he made his first appearance as a politician; he continued to practise as a logographer until he was about forty, by which time he had made a fortune sufficient to enable him to devote himself exclusively to political life until he died, at the age of about sixty-one.

At the beginning of his political career danger threatened Greece from the north, from Macedonia, a country which though at that time considered by the Greeks as semi-barbarous, and of no account in Greek politics, was destined within the lifetime of Demosthenes to destroy the liberties and the political existence of Greece. Demosthenes' claim to fame as a statesman rests on the fact that he foresaw the danger threatened by Philip of Macedon from the beginning, and that he from the outset advocated a policy which might have saved Athens and Greece. The three cardinal features of his policy were that the rich should submit to direct taxation for the purposes of the war; that the poor should submit, for the same purposes, to a diminution of the public expenditure on national festivals; and that rich and poor alike should render personal military service instead of employing mercenaries. Intelligent as was the Athenian democracy, it was not intelligent enough to see that Demosthenes' forecast was right, and his opponents' wrong; and, consequently, it was only when events justified Demosthenes, that is to say, when it was too late, that his policy was adopted. Philip's attack on the state of Olynthus gave occasion to the *Olynthiacs*, which, with the orations against Philip, the *Philippics*, are the greatest speeches made by Demosthenes. Athens made war with Philip on behalf of Olynthus, but having failed to save the city, found peace expedient. During the next few years (346-340) Demosthenes was engaged in forming an anti-Macedonian party, and in indicting Æschines for betraying Athens in the negotiations for the peace just concluded with Philip. War again broke out in 340, ending in the fatal battle of Chæronea (338). But Athens, having learned to trust Demosthenes, did not withdraw her confidence. The philo-Macedonian party, however, were encouraged to seize on a proposal to present Demosthenes with a public

crown as an occasion for his political destruction. The trial was at length held in 330, when in the famous speech *On the Crown* Demosthenes gloriously vindicated himself against Æschines. In 324 Harpalus, the treasurer of Alexander the Great (who had succeeded Philip), absconded to Athens with an enormous sum of money. This money was placed in the state treasury, under the care of Demosthenes and others, and when Alexander demanded it, half was missing. Demosthenes was accused, condemned, and escaped from prison into exile. The evidence does not seem to have warranted the verdict, which was probably given on political grounds, Demosthenes having offended both the Macedonian party and the extreme patriots. In 323 Alexander died, and Demosthenes was recalled from exile to head a fruitless attempt to throw off the Macedonian yoke. The battle of Crannon ended the revolt. Demosthenes fled to Calauria, and being there captured by Macedonian troops, poisoned himself, 322 B.C.

Demosthenes began life with a nervous, timid nature, and, unfortunately, as a boy was allowed by his mother to shirk the physical exercises and gymnastic training which formed part of the ordinary education of the young Athenian. He grew up with a tendency to effeminacy, which showed itself in an affection for luxurious clothing, and still more in his conduct as a citizen soldier; for although at Chersonæa he may have displayed no more cowardice than did the other Athenians who ran away, he was far from exhibiting the heroic bearing which distinguished Socrates at Delium. His timidity made him unsocial, and his water-drinking habits cut him off still more effectually from society. His luxury may have reached the point of extravagance: he was certainly lavishly generous in the discharge of all claims on him, public and private. Whether his effeminacy amounted to immorality, as was charged against him, is a question which cannot be answered off-hand in the negative. The natural defects which were to be seen in his private life may be traced in his public career; but here it is their conquest by force of will and determined adherence to a lofty purpose which has rightly given him his great name. His nervousness and timidity disqualified him for political life and public speaking; these defects he combated till he conquered them. His natural incapacity for amiability rendered him unsympathetic to the pleasure-loving Athenians; he compelled their respect by his intellectual power and the purity of his patriotism. The want of sympathy, however, he never overcame, and so he never obtained the hold over the Athenians which it would have been good for them that he should possess. In all democracies every politician who has led the masses at his own good-will has known on occasion how, if not to flatter, at least to say the thing that is pleasant; but Demosthenes' nature did not permit him to say pleasant things. Even this serious practical deficiency could not prevent his contemporaries from eventually recognising his force of character and steadiness of noble purpose. Still less has it weighed with posterity.

In the oratory of Demosthenes it is not difficult to trace the character of the man reflected. His resolute hard work and his infinite capacity for taking pains are seen in the high finish which distinguished his speeches above those of every orator. His moroseness is mirrored in the abuse of which he was too great a master; his want of amiability in the absence of humour. His nervousness betrays itself in his over-anxiety to argue, in his lack of ease and flow. But as in his life so in his speeches, all faults are blotted out by his unaffected earnestness, his entire devotion to his country, his intel-

lectual loftiness, and his high political morality. These great qualities are the source of the dignity, the pathos, the might, majesty, and dominion of his political orations. Even these qualities, however, would not have raised him to the highest pinnacle in the fane of eloquence had he not possessed the ear and the mind of the artist in words, the former of which gave to his speeches the marvellous melody they possess, the latter the variety of vocabulary, which is one of Demosthenes' characteristics. Nor must it be forgotten that the way for Demosthenes had been paved by great predecessors. The summit on which he stands rests on the labours of Lysias, Isocrates, and others. Finally, oratory, to be great, must have great themes, and it is not in every age that they are forthcoming. Demosthenes had the lot, tragic but triumphant, of saving, though all else was lost, the honour of his country.

For the life of Demosthenes. A. Schafer's *Demosthenes und seine Zeit* (2d ed. 1882-87) eclipses all other works, good as are the hand-books of Brodrick (1877) and Butcher (1881). The most exhaustive literary criticism is contained in Blass's *Attische Beredsamkeit* (1877). There are texts by Belcker (1854), Blass (1885-89), and Butcher (1903-7). Kennedy's English translation (5 vols. 1852-63) is a monument of scholarship.

**Demotica**, or DIMOTICA (Gr. *Didymoteichon*), a town of Thrace, on a tributary of the Maritza, 31 miles S. of Adrianople by rail. It is the seat of a Greek bishop, and has manufactures of silks and pottery. Pop. 16,000. Charles XII. of Sweden resided here from February 1713 to October 1714.

**Demotic Alphabet.** See **HIEROGLYPHICS**.

**Dempster**, THOMAS, a professor famous for his learning, and a miscellaneous and voluminous writer, was the son of Thomas, laird of Muirkirk, Aberdeenshire, and was born about 1579. He was educated at Turiff, Aberdeen, Cambridge, Paris, Louvain, Rome, and Douay. A zealous Catholic, he was elected to several provincial professorships, and at Paris he was for seven years professor in the Collèges des Grassins, de Lisieux, and de Plessy. But a brawl resulted, it is said, in Dempster's having to retreat to England. He soon returned to the Continent, bringing with him a beautiful wife, and at Pisa in 1616 obtained a professorship; but his wife's infidelities marring his peace, he removed to Bologna, where he became professor of Humanities, and where his wife completed her shame by eloping. Pursuing the fugitives, he was stricken with sickness, and died at Bologna, 6th September 1625. Dempster's not too veracious autobiography forms part of his *Historia Ecclesiastica Gentis Scotorum* (Bologna, 1627)—an erudite work in which, however, his desire to magnify the merits of his country often induced him to forge the names of persons and books that never existed, and unscrupulously to claim as Scotsmen writers whose birthplace was doubtful. It was edited by David Irving for the Bannatyne Club in 1829, and the manuscript is still preserved in the Bibliothèque Nationale, Paris. There is a selection from his Latin poetry in Johnston's *Delicia Poetarum Scotorum*.

**Demulcents** (Lat. *demulceo*, 'I soften'), bland and lubricating liquid substances, taken by the mouth, for the purpose of soothing irritation of the mucous membranes, and promoting the dilution of the blood, and the increase of the secretions. Demulcents are chiefly composed of Starch (q.v.), or Gum (q.v.), or of substances containing these, dissolved in water; sometimes also of oily matters, or the white of eggs, and other albuminous or gelatinous substances largely diluted. The decoction of althæa, or marsh-mallow, is a favourite form of demulcent.

**Demurrage** is an allowance made to a ship-owner by the freighter, for the detention of the ship in port beyond the specified time of sailing. The demurrage is properly the delay itself, but the term is generally used to signify the compensation due for the delay. A certain number of days, called lay-days or lie-days, are allowed for receiving and discharging cargo, and it is usually stipulated in charter-parties that the freighter may detain the vessel, either for a specified time, or as long as he pleases, after the expiration of these days, on paying so much *per diem* for overtime. Whether the days for which demurrage is due are *working days* (i.e. with Sundays and holidays excepted) or *running days* will, in the absence of special agreement, depend upon the custom of the port. All the ordinary causes of detention, such as port-regulations, the crowded state of the harbour, and the like, are at the risk of the freighter, and demurrage must be paid, though it be proved that the delay was inevitable. But demurrage is not due where the delay arose from detention of the ship by a public enemy, or from hostile occupation of the port; and it cannot, of course, be claimed where the fault lay with the owners themselves, or the master or crew of the vessel. The demurrage ceases as soon as the vessel is cleared for sailing, though she should be prevented from actually doing so by adverse winds. When the days of demurrage are limited by special contract, and the ship is detained beyond them, the sum due as demurrage under the contract will be taken as the measure of the loss for the further time which may be claimed in the form of damages. It will be open, however, to both parties to show that the rate thus fixed *per diem* is either too high or too low. When the time allowed for loading and discharging expires, including the extra days if such be stipulated, the master will be entitled either to sail or to claim damage for detention.

The term is now extended to other means of carriage, as railway wagons; and is also applied to the bank charge for giving coin in exchange for bullion.

**Demurrer**, in English law, is a form of pleading whereby a party, admitting, for the sake of argument, his opponent's allegations, says they are not sufficient in law to support his opponent's case. A demurrer must be argued in court before the pleadings can proceed further. Demurrer to evidence and demurrer to a criminal indictment are now obsolete. If a prisoner wishes to object to the sufficiency in law of an indictment, his best course is to plead to the indictment, and, if convicted, to move in arrest of judgment.

**Demy**, a particular size of paper. In that of printing paper, each sheet measures 22 inches by 17½; drawing-paper, 22 by 17; and writing-paper, 20 by 15½.

**Demy** (i.e. *half-fellow*), the name borne by the scholars of Magdalen College, Oxford.

**Denain**, a town in the French department of Nord, near the Scheldt and Selle rivers, 20 miles NNE. of Cambrai by rail. It lies in the centre of an extensive coalfield, and has important iron-works, with manufactures of glass, beetroot sugar, and brandy. An obelisk marks the scene of Marshal Villars' victory over the allies under Prince Eugene, 27th July 1712. Pop. 23,500.

**Denali**, native name of Mount McKinley (q.v.).

**Denarius** (*deni*, 'ten each'), the principal silver coin among the Romans, was equal to ten *asses*, but upon the reduction of the weight of the *as*, the denarius equalled sixteen of it. It was first coined 269 B.C. Its weight at the end of the Roman commonwealth is estimated at 60 grains, while under the empire the weight was 52½ grains of silver. The value of the denarius under the republic

was thus rather more than 8½d., and of the later

Denarius of the earliest kind, actual size; weight, 60·6 grains.

period about 7½d. From *denarius* come the Persian *dinār* and the English slang *deaner*, 'a shilling.'

**Denary Scale.** See SCALES OF NOTATION.

**Denbigh**, a municipal borough, the county town of Denbighshire, 30 miles W. of Chester by rail. It stands near the middle of the Vale of Clwyd, on the sides and at the base of a rugged steep limestone-hill. The castle, whose imposing ruins crown this hill, was built in 1284 by Henry Lacy, Earl of Lincoln, on the site of a fortress erected by William the Conqueror. The newer part of Denbigh was built at the bottom of the hill, after the destruction and desertion of a great part of the town on the top of the hill, about 1550. Denbigh has manufactures of shoes and leather; but it is more a place of genteel retirement than of commerce. Pop. 7000. With Ruthin, Holt, and Wrexham, Denbigh (now merged in the county) sent one member to parliament till 1918. In 1645 Charles I. took refuge in the castle after the battle of Rowton Heath. The garrison surrendered to the parliamentary forces after a siege of two months. It was shortly afterwards dismantled. The fortifications have an area of a square mile in extent. A lunatic asylum for the five counties of North Wales was erected near the town in 1848. A noble institution for the maintenance and education of twenty-five orphan girls, and twenty-five day pupils, was built here in 1860, with funds in the hands of the Drapers' Company of London, from money left to them in 1540 by one Thomas Howell, a Welshman.

**Denbighshire**, a county of North Wales, on the Irish Sea, and between the Dee and the Conway. With 8 miles of coast, it is 41 miles long, 17 broad on an average, and 666 sq. m. in area, being the sixth in size of the Welsh counties. The surface is partly rugged and mountainous, with some beautiful and fertile vales, as the vale of the Clwyd, 20 miles by 7, and those of the Dee and Conway. In the north is a range of hills, convex to the coast. The highest hill is Cader Idronwen, 2563 feet; and many others rise above 1500 feet. The rocks are chiefly Silurian clay and graywacke slates, with some granite and trap, and bands of Devonian, Carboniferous, and Permian strata. There occur coal, iron, slates, flags, millstones, limestone, lead, zinc, and copper. The chief rivers are the Dee, Conway, Elwy, and Clwyd. The Rhaiadr waterfall is 200 feet high in two parts. Llangollen vale is famed for romantic beauty and verdure, amid hills of savage grandeur. The climate is mild in the lower parts, but cold and bleak among the hills, where small hardy sheep and ponies are reared. About two-thirds of Denbighshire are under cultivation; its corn, cheese, butter, and live-stock are greatly esteemed. It is also well timbered. Salmon are caught in the rivers. The chief towns are Denbigh, Wrexham, Ruthin, Holt, Llangollen, Llanrwst, Abergele, and Rualon. Pop. (1801) 60,299; (1841) 88,478; (1921) 154,847. Denbighshire returns two members to parliament. It was anciently occupied by the Ordovices, a powerful tribe, not entirely subdued by the Romans till the

time of Agricola. Of British or pre-Roman remains there still exist tumuli, two kistvaens or stone cells, barrows, and forts. To the times of the Welsh and Saxon struggles are referable the Pillar of Eliseg, near Llangollen, and the dikes of Offa and Watt. The dike of Offa, king of Mercia, to keep out the Welsh, was a ditch, with small forts on mounds at intervals, and ran from Herefordshire to the estuary of the Dee; Watt's dike ran on the east side of Offa's dike, and parallel to it. Wrexham Church is one of the 'seven wonders of Wales.' Chirk Castle is a fine Edwardian stronghold, restored.

**Dendera** (Gr. *Tentyra*; Coptic *Tentore*, probably from *Téi-n-Athor*, the abode of Athor), a village of Upper Egypt, once a populous town, and the capital of the sixth nome of the 'southern kingdom,' situated near the left bank of the Nile, in 26° 10' N. lat., 32° 40' E. long., is celebrated on account of its temple, one of the finest and best preserved structures of the kind in Egypt, dating from the period of Cleopatra and the earlier Roman emperors. The temple measures about 300 feet in length by 135 in breadth, and includes a noble portico or hypostyle hall supported on twenty-four columns. The walls, columns, &c. are covered with figures and hieroglyphics, among which are still to be seen the contemporary portraits in profile of Cleopatra and her son; but the beauty of the Egyptian queen is not apparent in her portrait, which belongs to almost the most degraded period of conventional art in Egypt. Certain zodiacs among the decorations turn out to be late, and the theories based on their antiquity fall. Beyond the portico are a hall of six columns and several rooms, which once contained altars, the sacred boats, perfumes, vestments, and offerings of first-fruits, and the like (Mariette, *Denderah*, 1869-80). There are several other sacred buildings at Dendera, including a temple of Isis. The temples stand within a wall of unbaked bricks, 1000 feet long on one side, and in some parts 35 feet high. As worshippers of Athor, consort of Horus, who was the enemy of the hippopotamus of Set, the Tentyrites were hostile to the people of Ombos, near Coptos. See Juvenal, *Satire* xv., and Petrie's *Denderah* (1900).

**Dendermonde** (Fr. *Termonde*), a town of Belgium, in the province of East Flanders, situated at the confluence of the Dender and the Scheldt, 17 miles E. of Ghent. The principal buildings were the town-house and the church of Notre Dame, containing two pictures by Van Dyck. The manufactures are linens, cottons, and beer. Louis XIV. besieged it in vain in 1667, but Marlborough succeeded in taking it in 1706. Its fortifications, destroyed in 1784, were restored in 1822. The town was taken by the Germans in September and in October 1914, and burned. Pop. 10,000.

**Denderpeton**, a small lizard-like Carboniferous Labyrinthodont, first found in the hollow trunk of an upright *sigillaria* in Nova Scotia.

**Dendrites**, the name given to thin films of mineral matter which assume branching shapes that resemble moss or seaweed. These films occur as coatings on the faces of fissures and joints in rocks or on the surfaces of bedding-planes, and have often been mistaken for fossils.—**DENDROLITES** is a name sometimes given to fossil stems, branches, or other fragments of trees.

**Dendrophis**, or TREE-SNAKE, a genus of Colubrid, non-venomous tropical snakes; see SNAKES.

**Deneholes**, or DANEHOLES, well-like shafts sunk through superincumbent strata to the chalk beneath, familiar in Kent and Essex and in the French valley of the Somme. The name seems to have been transferred from excavations believed to have been made by Danish invaders; but the

deneholes specifically so called have been variously described as places for hiding plunder, retreats for fugitives in time of war, or as shafts sunk to get at the chalk and flints, especially for the supply of Flint Implements (q.v.). Bone picks have often been found in deneholes. See an elaborate article by F. C. J. Spurrell in the *Archæological Journal* for 1881; *Notes and Queries*, series vi. and vii.; *Nature*, June 1907; W. Johnson, *Folk Memory* (1908).

**D'Enghien**. See ENGHEN.

**Dengue**, or BREAK-BONE FEVER, also called DANDY and BUCKET FEVER, is a disease first certainly known to have occurred in 1779-80 in Egypt, parts of the East Indies, and probably in Philadelphia. Since that time there have been great epidemics in India and Further India (1824-25), America and West Indies (1826-28), Southern United States (1850), East Africa, Arabia, India, and China (1870-73), besides numerous minor outbreaks. The disease occurs almost exclusively in the tropics, in hot weather, and in towns either near the sea-coast or on large rivers. It is characterised by sudden onset, with high fever, and extremely violent pains in the bones, muscles, and joints; by a remission, usually at the end of one or two days, during which the patient feels almost well; and after one or two days more by a second period of fever, less severe than the first, which lasts for two or three days. Each attack of fever is often accompanied by a well-marked skin-eruption. Though often followed by much emaciation and loss of strength, it is very rarely fatal or succeeded by serious after-effects. It occurs almost always in well-marked epidemics; and the infection, though its nature is not known, is believed to be transmitted by the bite of a mosquito (*Culex fatigans*).

**Denham**, SIR JOHN, a Caroline poet, was the only son of an Irish judge, himself of English birth, and was born at Dublin in 1615. He was educated in London and at Trinity College, Oxford, where Wood tells us he was 'a slow dreaming young man, and more addicted to gaming than study'—a taste for which his own essay against gaming (1651) did not cure him. In 1634 he married and went to live with his father at Egham in Surrey, an estate to which he succeeded four years later. At the outbreak of the Civil War he was high-sheriff of Surrey, and he immediately joined the king. He fell into Waller's hands on the capture of Farnham Castle, and was sent prisoner to London, but soon permitted to repair to Oxford. In 1641 he produced *The Sophy*, a feeble tragedy which was acted with great applause at Blackfriars. Next year was issued his long poem, *Cooper's Hill*, a poetical description of the scenery around Egham, itself still read, but more famous in the merits of its greater successor, Pope's *Windsor Forest*, which was avowedly an imitation of it. The final form of the poem is that published in 1655, all the changes in which, according to Pope, were made 'with admirable judgment.' Here first appeared its finest lines—the famous apostrophe to the Thames:

O could I flow like thee, and make thy stream  
My great example, as it is my theme!  
Though deep yet clear, though gentle yet not dull,  
Strong without rage, without o'erflowing full.

In 1647 Denham was engaged in the performance of secret services for Charles I., but these being discovered, was obliged to flee to Holland and France. In 1650 he collected money for the young king from the Scots resident in Poland, and he made several journeys into England on secret service. At the Restoration he was appointed surveyor-general of works, and created Knight of the Bath. He was a better poet than architect,

but he had Christopher Wren to his deputy. In 1665 he married a young girl, who soon showed open favour to the Duke of York. The poet became crazy for a few months, and about the time of his recovery his wife died suddenly, not without suspicion of poison—a charge which Pepys and Marvell evidently believed. Denham's last years were miserable betwixt poverty and the satires of Butler and others. He died early in 1669, and was buried in Westminster Abbey. His *Elegy on Cowley*, written in the short interval between recovery from frenzy and his death, is one of his most successful poems, and is much less obscure and laboured, ungrammatical, and overlaid with tedious moralising, than usual. His other works, as the *Destruction of Troy*, a paraphrase of part of the *Æneid*, and especially his satirical doggerel verses, are comparatively worthless. 'Nothing,' says Dr Johnson, 'is less exhilarating than the ludicrousness of Denham; he does not fail for want of efforts; he is familiar, he is gross; but he is never merry.' His fame rests securely on *Cooper's Hill*, but more securely still on the commendations of Dryden, Pope, Swift, and Johnson. He is especially eulogised for his *strength*, as Waller is for his *sweetness*; indeed, Dryden's critical judgment stands expressed in the words that *Cooper's Hill* 'for the majesty of its style is and ever will be the standard of exact writing.'

**Denia**, a port on the coast of the Spanish province of Alicante, near Cape St Martin. It exports grapes, raisins, and fruit, and has a population of 13,000.

**Denikin**, ANTON, Russian White leader, born in 1872, son of a serf, entered the army in youth, and in 1917 was in command in Rumania. Kerensky made him chief of staff to Alexeiev and afterwards Brusilov. Arrested after the Kornilov rising, he escaped, and joined the anti-Bolshevik forces in the south, of which the deaths of Kaledin, Kornilov, and Alexeiev left him leader. In 1919 he swept northwards and westwards, taking Kharkov, Poltava, Odessa, Kiev, and Orel, and establishing some sort of contact with Koltchak's army in the east. His aim of a united Russia alienated the Ukrainians; Koltchak's collapse left the Bolsheviks free to concentrate against him; help from the Allies was diminished; and Denikin was quickly driven back to the Black Sea. Novorossisk, his last base, was taken in March 1920.

**Denina**, CARLO GIOVANNI MARIA, an Italian author, was born 28th February 1731, at Revello, in Piedmont, studied at Turin, and in 1758 became professor of Rhetoric in the university of Turin. In 1777 he published anonymously at Florence his *Discorso sull' Impiego delle Persone*, in which he sought to show how monks might be transformed into useful members of society. This cost him his chair, and caused his banishment. In 1782 he went to Berlin on the invitation of Frederick the Great. Here he lived for many years, and wrote many historical works. In 1804 he dedicated to Napoleon his great *Clef des Langues*, and was in consequence appointed imperial librarian at Paris, where he died 5th December 1813.—Denina's principal works are *Delle Rivoluzioni d'Italia* (3 vols. 1770) and *Storia dell' Italia Occidentale* (6 vols. 1810), besides works on ancient Greece, Frederick the Great, and Prussia.

**Denis**, St, the traditional apostle of France and first Bishop of Paris, who suffered martyrdom in the 3d century. He was sent from Rome about 250 to preach the gospel to the Gauls. After various detentions at Arles and other places, he arrived in Paris, where he made numerous proselytes. The Roman governor of this part of Gaul ordered

Denis to be brought before him, along with other two Christians. As they continued firm in their faith, in spite of threats, they were cruelly tortured, and afterwards beheaded, in 273 or in 290. Gregory of Tours, Fortunatus, and the Latin martyrologists, state that the bodies of the three martyrs were thrown into the Seine, but were recovered and buried by a Christian woman. At a later period a chapel was built over their tomb. In 636 King Dagobert founded on the spot an abbey, called St Denis, which soon grew to be one of the richest and most important in the whole kingdom, and was long the sepulchre of the French kings. The collection entitled the *Acts of St Denis*, written about the end of the 7th or beginning of the 8th century, has no historical value. The Greek Church identifies St Denis with Dionysius the Areopagite, first Bishop of Athens. The Western Church celebrates his memory on the 9th of October. For a long period his name was the war-cry of the French soldiers, who charged or rallied to the words 'Montjoye Saint-Denys!'

**Denis**, MAURICE, French post-impressionist painter and art-critic, was born at Granville (Manche) in 1870, and was much influenced by Gauguin and Cézanne. His mural work is notable.

**Denison**, JOHN EVELYN, for fourteen years Speaker of the House of Commons, and afterwards Viscount Ossington, was born 27th January 1800, at Ossington, Nottinghamshire. Educated at Eton and Christ Church, Oxford, he entered parliament in 1823, and was a Lord of the Admiralty 1827–28. In 1872 he retired from the Speaker's chair, and shortly after was created Viscount Ossington. He was a D.C.L. of Oxford; and it was on his suggestion that the *Speaker's Commentary* to the Bible was undertaken. He died 7th March 1873.—His brother, GEORGE ANTHONY DENISON, Archdeacon of Taunton, was born in 1805, and educated at Eton and Christ Church, Oxford, in 1828 being elected a Fellow of Oriel. In 1843 he became Vicar of East Brent, Somerset; in 1851 Archdeacon of Taunton. In 1854 proceedings were taken against him for heresy, contained in three sermons on the *Real Presence*, and he was condemned to be deprived of all ecclesiastical preferments; but on appeal to the Court of Arches and the Privy-council, this judgment was quashed. A leader of the High Church party, he opposed secular education, advocated confession, and was chairman of the Committee of Convocation which condemned *Essays and Reviews* and Bishop Colenso's works. He died 21st March 1896. See his delightful *Notes of my Life* (1878–93).—Other brothers were Edward, Bishop of Salisbury (1801–54), and Sir William Thomas, Governor of New South Wales and Madras (1804–71).

**Denman**, THOMAS, BARON, was born in London, 23d February 1779, graduated at Cambridge, and entered Lincoln's Inn in 1806. He was associated with Brougham in the courageous defence of Queen Caroline (1820), and shared his consequent popularity. He sat in parliament in 1818–26, and was Attorney-general in Earl Grey's administration in 1830–32; he succeeded Lord Tenterden as Lord Chief-justice of England in 1832, and was raised to the peerage in 1834. He retired from the bench in 1850, and died 22d September 1854. See *Memoir* by Sir Joseph Arnould (2 vols. 1873).—His seventh son, the RIGHT HON. GEORGE DENMAN, was born 23d December 1819, studied at Cambridge, and was called to the bar in 1846. He represented Tiverton in parliament in 1859–65 and 1866–72; in 1872 he was raised to the bench of the Court of Common Pleas, and in 1873 he became a judge of the High Court of Judicature. He retired in 1892, being made a Privy-councillor, and died 21st September 1896.

**Denmark** (Dan. *Danmark*), the smallest of the Scandinavian kingdoms, consisting of the peninsula of Jutland, some of the North Frisian Islands, a group of islands in the Baltic, and the Faeroes, is situated between 54° 33' and 57° 45' N. lat., and 8° 4' and 12° 47' E. long., excepting the small island of Bornholm, which reaches 15° 10' E. long., and the Faeroe Islands in 62° N. lat. and 6° W. long. Denmark is bounded on the N. by the Skagerrak; on the E. by the Cattegat, the Sound, and the Baltic; on the S. by the Baltic, Little Belt, and Schleswig-Holstein; and on the W. by the North Sea. The area is more than half that of Scotland; the population over two-thirds. The population in 1870 was 1,784,741; in 1921 it had increased to 3,289,195. In 1921 the population of Copenhagen was 561,344 (with suburbs, 710,353); and including these suburbs there were five other towns with over 30,000 inhabitants—Frederiksberg (105,000), Aarhus (74,000), Odense (49,000), Aalborg (42,000), Gentofte (34,000). Next in size are Horsens (28,000), Randers (26,000), Vejle (22,000), Esbjerg (21,000), Fredericia, Kolding, and Elsinore (Helsingør).

The following table gives the main divisions of the kingdom, along with its dependency:

	Area in Eng sq miles	Population in 1921
Copenhagen .....	81	666,159
Islands in the Baltic, comprising Zealand, Funen, Læ- land, Fåltet, &c., without Copenhagen .....	5,180	1,103,198
Peninsula of Jutland .....	11,467	1,498,479
Faeroe Islands .....	540	21,864
Denmark .....	17,168	3,289,195
Colony—Greenland (region free from ice) .....	38,000	18,459
Total .....	50,168	3,302,654

Except in Bornholm (q.v.), the surface of Denmark is very similar in every part of the kingdom, and is uniformly low, reaching its highest point in Eiers-Bavnehøj, in south-east Jutland, which is only 564 feet above sea-level. The country presents little variety, except in its low isolated hills, but does not leave an impression of monotony; in the islands and in the south-east of Jutland the landscape is broken by noble forests, green meadows, and fertile fields; and even in the west and north of the mainland the wide stretches of moorland are clothed with heather, and have a solemn beauty of their own. The coast seldom rises even to low cliffs; generally it is flat, skirted by sand-ridges and shallow lagoons, especially along the west side. The east coast is much indented by bays, useful for navigation and valuable for their fisheries; and here and in the islands are many good harbours. Both the continental portion and the islands are penetrated deeply by numerous fjords, the largest being Limfjord, which intersects Jutland, and has insulated the northern extremity of the peninsula since 1825, when it broke through the narrow isthmus which had separated it from the North Sea. From its formation, the kingdom can have no rivers, properly so called; its streams, called *Aa*, are mostly large brooks. There are several important canals, however, including in Jutland works for the canalisation of the Guden-Aa, its largest stream, and of the Limfjord; and lakes abound in all parts of the kingdom, the most considerable being found in Zealand. The centre and west of Jutland were nearly bare of wood, but in modern times there has been much planting of Norway spruce and mountain pine. In other parts of the peninsula and in the islands there are forests. About 6 per cent. of the whole

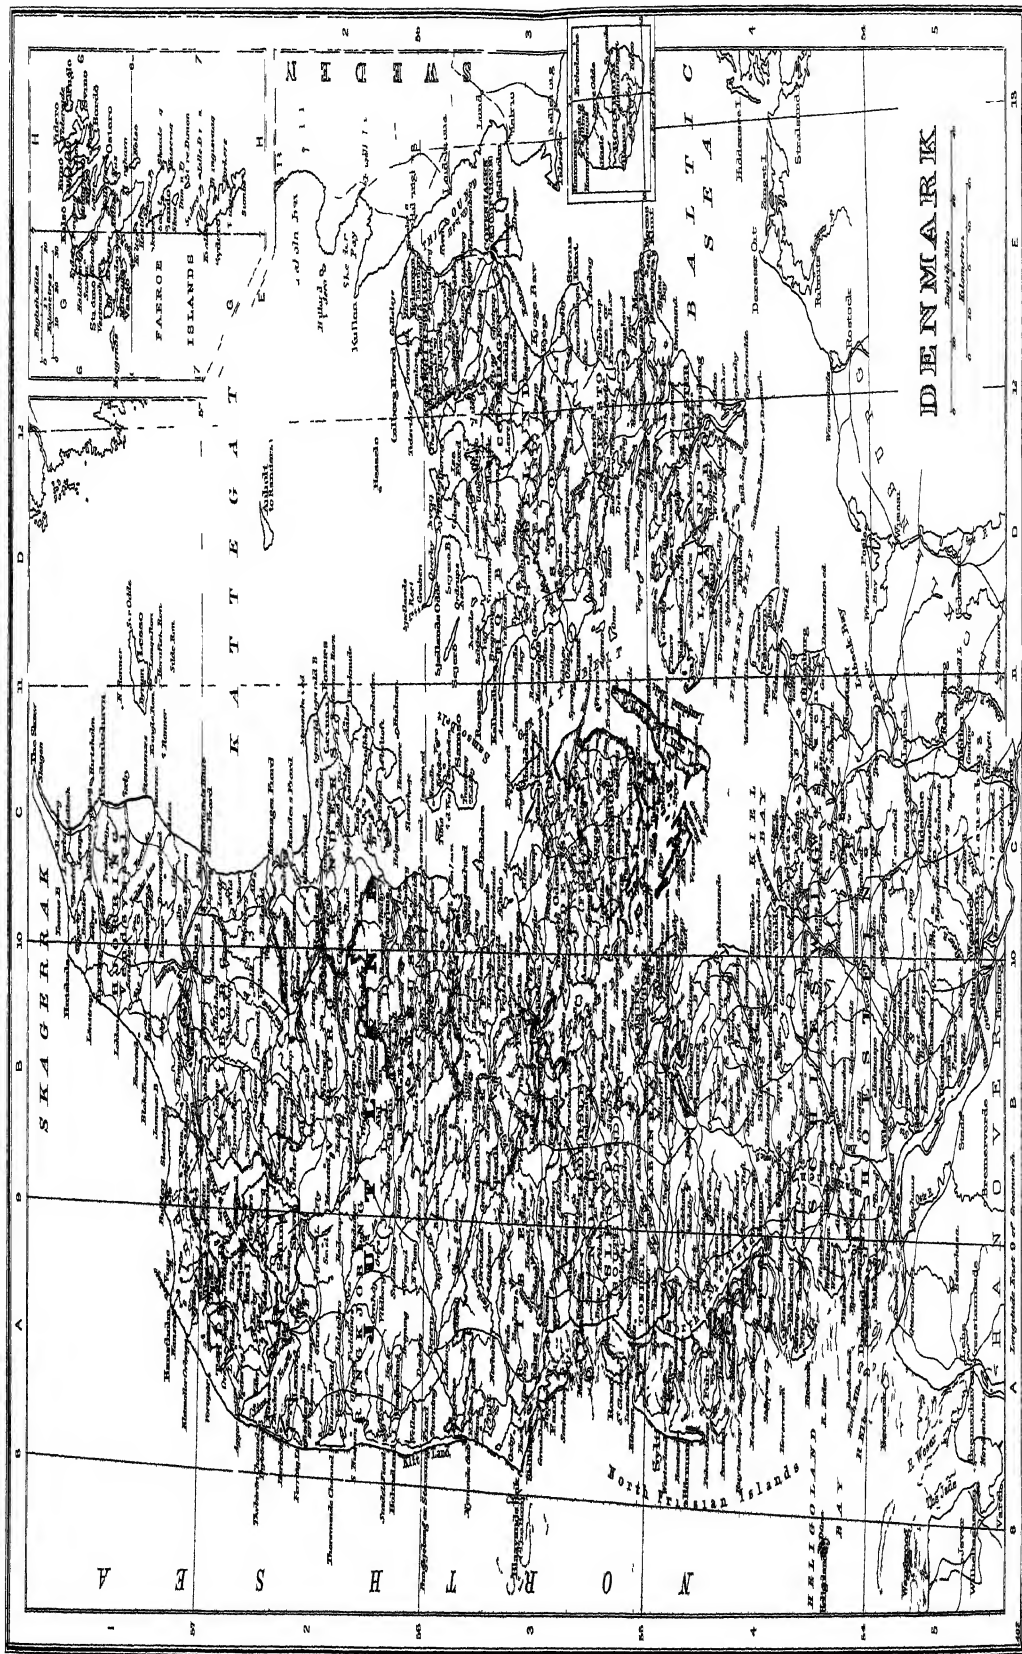

productive area is under wood. The beech, which flourishes more luxuriantly in Denmark than in any other land, is almost universally predominant, although three centuries ago the oak, now comparatively rare, was the characteristic Danish tree. Peat, which is got in abundance from the bogs, brown coal or lignite, and seaweed generally take the place of wood as fuel. In minerals Denmark is poor. Porcelain clay and some coal are found in Bornholm, and fuller's earth, potter's clay, saltpetre, chalk, and a poor marble occur in several parts of the kingdom, while some amber is collected on the west coast of Jutland. The climate is modified by vicinity to the sea, and is considerably milder, and the air more humid, than in the more southern but continental Germany. Mists are frequent, as are also sea-fogs on the west coast; and rain, snow, or hail falls over the country on 150 days on an average in the year. The annual rainfall is 23 to 25 inches. Westerly winds prevail; in the spring a cold, dry wind blows from the north-west, and whiffs clouds of fine sand from the coast inland, frequently doing irreparable damage to the crops. The mean temperature ranges from 44° to 47° F. The transitions between winter and summer are rapid, and scarcely broken by the intervention of spring or of autumn. The climate is, however, not unhealthy, except in the low-lying islands, such as Lolland, where the short and sudden summer conduces to fevers.

The soils of Jutland are generally light, but those in the south-east part and in the islands are stronger; about 80 per cent. of the area of Denmark is productive, and of the remainder about one-sixth is in peat-bogs. Nearly half the population lives by agriculture; the land for the most part is parcelled out into small holdings, and this is encouraged by the laws, which since 1849 have prohibited the throwing of small farms into large estates. Of tenancies, very few exceed a quarter of a square mile in extent; there are many cottars and labourers cultivating land of from three to twelve acres; and the 'peasant farms'—the majority under 50 acres—are also numerous. A third of the whole kingdom is arable, while over two-fifths is in meadow, pasture, or fallow land. The chief grain crops are oats, barley, and rye, but wheat is also grown. Flax, hemp, potatoes, and leguminous plants are raised; lucerne has been introduced, and the cultivation of the beet-root has increased. Barley is largely exported, but the imports of breadstuffs greatly exceed the exports. The raising of cattle more and more took the place of arable farming in Denmark, till it became one of the chief sources of wealth. Much progress has been made in this direction owing to the efforts of government and of various institutions; bull and stallion shows have been promoted by royal grants, breeding farms have been similarly encouraged, and the farmers have been instructed by lectures on the various forms of cattle disease and other subjects. The stock of horses, cattle, swine, and sheep is very large; in 1922 there were in Denmark 576,000 horses, 2,525,000 head of cattle, 442,000 sheep, and 1,899,000 swine. Many animals are exported. The live-stock trade is now overshadowed by that in dairy produce, bacon, and eggs, which has largely developed, owing to improved methods, to the spread of scientific instruction, and to the co-operative dairy system, now worked successfully on a large scale. Much brandy and beer is produced.

About a third of the inhabitants are engaged in manufacturing industries, which, although not yet of great importance, show a marked advance. Machinery, porcelain and delf, bricks, and margarine are leading manufactures; beet-root sugar refineries are increasing, distilleries declining;

IDENTIFIK

there are ironworks, shipyards, tobacco-factories, and several paper-mills in Copenhagen, Silkeborg, and elsewhere; and there are many large steam corn-mills. Generally, in spite of the scarcity of fuel in the country, steam-mills are taking the place of the windmills, and though the peasants still continue to manufacture much of what they require within their own homes, linens and woollens, as well as wooden shoes, are now increasingly made in factories. The fisheries (including the lobster and oyster fisheries) and the mercantile marine employ less than 3 per cent. of the people.

The principal articles of export are butter, meat, eggs, fish, hams, grain, ships, hides, cattle, sheep, swine. Among the imports are coal, metal goods, oil-cake, textile fabrics, cereals, flour, and timber goods. The bulk of the foreign trade is with Germany, Great Britain, the United States, Sweden, Russia, and Norway. There are 2700 miles of railway open, of which 1300 belong to the state; and there are extensive telegraph lines, mostly state property.

Elementary education is widely diffused, although in this regard Denmark is no longer so pre-eminent as formerly; it is compulsory for children between the ages of seven and fourteen years, and for the most part gratuitous in the government and parochial schools, of which there are about 3500. There are training-colleges for teachers, and classical and other higher education is afforded by a large number of colleges in the more important towns, with the university of Copenhagen for the centre of the entire system. There are three public libraries in Copenhagen, of which the Royal Library, with 500,000 volumes, is especially rich in oriental and Icelandic MSS. The established religion is Lutheran, to which the king must belong; but complete toleration is enjoyed in every part of the kingdom. The Reformation was introduced in 1536, when the church revenues were seized by the crown. Denmark is divided into eight dioceses. There were in 1921 3,222,000 Protestants (mostly Lutherans), 22,000 Roman Catholics, 6000 Jews, and 18,000 others. The only overseas possession of Denmark is Greenland (q.v.). The Danish West India islands (see VIRGIN ISLANDS) were sold to the United States in 1917. Iceland was recognised as a sovereign state in 1918.

The government of Denmark is a constitutional monarchy, the king being assisted by a cabinet. The crown was elective until 1660, when the people and clergy, impelled by hatred towards the nobles, invested the sovereign (Frederick III.) with absolute power, and declared the succession to the throne hereditary. From that time the crown exercised absolute rule till 1831, when a constitution was granted. This, proving unsatisfactory, was superseded in 1848 by the form of government which, with some alterations, Denmark enjoyed till 1915, when important changes were made. The national assembly or Rigsdag consists of the Folkething and Landsting, which meet annually, the members receiving an allowance which varies according as their homes are in Copenhagen or elsewhere. The Landsting is composed (since 1920) of 76 members, 56 indirectly elected for eight years by proportional representation for large electoral divisions, and retiring in two sections; 1 for the Faeroes; 19 elected for eight years by proportional representation by the outgoing house. The former privilege of the larger taxpayers has been abolished. The 149 members of the Folkething are directly elected for four years by practically universal suffrage, on the system of proportional representation, 31 seats being allotted to candidates unsuccessful in the constituencies. Women have the franchise, and are eligible for both houses. To the Folkething body all budgets must first be submitted; but in the years 1877-87, when the

government had a minority in the lower house, the king was induced to give the royal ratification to successive 'provisionary budgets,' which had never received the assent of the Rigsdag. The financial condition of Denmark is sound and prosperous. The decimal system was introduced in 1875, the unit being the *krona*, or crown, of 100 *ore*; the average rate of exchange is 18.16 *kroner* to the pound sterling. Compulsory service prevails, and the period is divided into eight years in the first ban, and eight in the second. Service begins at the age of twenty. After 150 days' training in the infantry, or a longer period in the engineers or cavalry, a minority remain in the army for a further period of 2½ to 8½ months. There are subsequent short periods of training. On emergency over 100,000 men could take the field. The navy is recruited by levies from the coast districts, and is maintained for purposes of coast defence. Copenhagen (q.v.) is a fortress, but its land defences were abolished in 1920-22. The arsenal is at Copenhagen.

*History.*—The early history of Denmark is lost in the twilight of the saga-period, out of which loom dimly the figures of its heroes, their brave deeds, and daring voyages. Within its borders the Cimbrii had first their home, and from its shores the Jutes sailed in the 5th century to the conquest of England; while in their place the Danes from Zealand settled on the deserted lands, extending their sway as far south as the Eider. One of their earliest kings, Harald Hildetand, fell in battle against the Swedes in 695; and shortly afterwards a branch of the Ynglinger occupied Jutland, where they held a footing for two centuries. One of their kings, Harald Klak, received baptism in 826 from Ansgar (q.v.); but the introduction of Christianity did not at once place any check on the long-accustomed inroads on Frankish territory, or on the piratical expeditions of the Vikings, although the country was soon torn by dissensions between the adherents of the old and new faiths. Gorm the Old, who drove the Ynglinger from the peninsula, and first united the mainland and islands under one rule, was the bitter enemy of Christianity; and although his death in 936 gave fresh vigour to the diffusion of the new faith, yet even its ultimate success was only ensured by the zealous support it received from Gorm's great-grandson, Cnut (q.v.). On his death in 1035 the three kingdoms of his Anglo-Scandinavian empire separated, and his sister's son, Svend Estridsen (1047-76), ascended the throne of Denmark, founding a princely line that flourished 400 years. Internal dissensions and external wars weakened the country, and the introduction of a feudal system raised up a powerful nobility, and ground down the once free people to a condition of serfdom. Waldemar I. (1157-82) added Rügen to the other Wendish districts of Mecklenburg and Pomerania, and extended his sway over Norway also. Under Waldemar II. the conquests of Denmark extended so far into German and Wendish lands that the Baltic was little more than an inland Danish sea. The jealousy of the German princes and the treachery of his vassals combined to rob him, however, of these brilliant conquests, and his death in 1241 was followed by a century of anarchy and inglorious decadence of the authority of the crown, during which the kingdom was brought to the brink of annihilation. Under his great-grandson, Waldemar IV., Denmark made a transient recovery of the conquests of the older Waldemars, rousing the jealousy of the Hanseatic League (q.v.), and the national laws were codified. From his death in 1375 till 1412, his daughter, the great Margaret, widow of Hakon VI. of Norway, ruled not only that country and Denmark, but in

course of time Sweden also, with so light yet firm a hand that for once in the course of their history the three rival Scandinavian kingdoms were content to act in harmony. Margaret's successor, Eric, the son of her niece, for whose sake she had striven to give permanence, by the act known as the Union of Calmar (1397), to the amalgamation of the three sovereignties into one, undid her glorious work with fatal rapidity, lost the allegiance and the crowns of his triple kingdom, and ended his disastrous existence in misery and obscurity. After the short reign of his nephew, Christopher of Bavaria (1440-48), the Danes exerted their ancient right of election to the throne, and chose for their king Christian of Oldenburg, a descendant of the old royal family through his maternal ancestress, Rikissa, the great-granddaughter of Waldemar II. Christian I. (1448-81), who was at the same time elected Duke of Sleswick and Holstein, was the founder of the Oldenburg line, which continued unbroken till the death of Frederick VII. in 1863. His reign was followed by half a century of international struggles in Scandinavia. The insane tyranny of Christian II. (q.v.) cost that monarch his throne and freedom; the Danes chose his uncle Frederick I. to be their king, while Sweden was for ever separated from Denmark, and rose under the Vasas (see GUSTAVUS I.) to be a powerful state.

Under Christian III. (1536-59), the Reformation was established in Denmark. Christian IV. (q.v.), after his brief share in the 'Thirty Years' War, proved one of the ablest of all the Danish rulers. His liberal and wise policy was, however, cramped in every direction by the arrogant nobles, to whose treasonable supineness Denmark owes the reverses by which she lost (1658) all the possessions she had hitherto retained in Sweden; and with the relinquishment of these, and consequently of the undivided control of the passage of the Sound, the country's former international importance came finally to an end. The national disgraces and abasement which followed led, in 1660, under Christian's son, Frederick III., to the rising of the people against the nobles, and their surrender into the hands of the king of the supreme power. For the next hundred years, chiefly marked by wars with Sweden, the peasantry were kept in serfdom, and the middle classes depressed; but by the end of the 18th century the peasants had been gradually emancipated, while many improvements had been effected in the mode of administering the laws, and the Danish kings, although autocrats, exercised a mild rule. The miseries of the reign of Frederick VI., who governed as regent from 1784, brought the country to the verge of ruin. Denmark having joined Russia in a compact of the Northern Powers hostile to England, a fleet was sent into the Baltic, and considerable injuries were inflicted by an attack on Copenhagen, in 1801, under Parker and Nelson. From this the country rallied; but in 1807 the British government, suspicious of an intention on the regent's part to violate his neutrality and take sides with Napoleon, demanded the surrender of the entire Danish navy, to be restored at the conclusion of peace. A refusal was followed by the bombardment of Copenhagen in September 1807, and the fleet was given up; but this treatment drove Denmark into Napoleon's arms, and with him the kingdom was obliged to co-operate until the close of 1813.

By the congress of Vienna, Denmark was compelled to cede Norway to Sweden. From this period a spirit of discontent grew up in the duchies, degenerating into mutual animosity between the Danish and German population, which led to an open rupture with Denmark in 1848, immediately after the accession of Frederick VII. (For the

whole question, see SLESWICK-HOLSTEIN.) After alternate hostilities and armistices, the war was virtually concluded in 1850, by the victory of the Danes at Idsted; but in 1863 the quarrel was renewed. On the death of Frederick in that year, Prince Christian of Sleswick-Holstein-Glucksborg ascended the throne under the title of Christian IX., in conformity with the act known as the Treaty of London of 1852, by which the succession to the Danish crown had been settled on him and his descendants by his wife, Princess Louise of Hesse-Cassel, niece of King Christian VIII. of Denmark. A pretender, backed by German influence and help, at once started up in the person of the eldest son of the Duke of Augustenburg, who assumed the title of Duke Frederick VIII. of Sleswick-Holstein; but his cause was speedily merged and lost sight of by Prussia and Austria in their direct aim of incorporating the duchies with the German Confederation. Denmark, unaided by England and France, allies on whose support she had relied, was forced to go single-handed into the unequal contest. After a brave but utterly futile attempt at resistance, the Danes found themselves forced to submit to the terms dictated by their powerful foes, and resign not only Lauenborg and Holstein, but the ancient crown-appanage of Sleswick (1864). The dissensions between Prussia and Austria led to the Austro-Prussian war of 1866, and the duchies remained an integral part of Prussia. The Treaty of Versailles divided Sleswick into three zones, whereof the southernmost (with Holstein) should remain definitively German, the northernmost should as a unit choose by plebiscite between Germany and Denmark, and if it elected to be Danish, a plebiscite of the middle zone should then be taken by communes. The northern zone voted for Denmark (about 3 to 1), the middle zone for Germany (4 to 1). Northern Sleswick thus became a Danish province (Sonderjydske Landsdele, 1500 sq. m., with 163,622 inhabitants in 1921). See SLESWICK. Meanwhile socialism has spread. Political dissensions ranged the government and Landsting, supported by the press of the capital, against the Folkething and majority of the people; but the constitution was reformed in 1915 (see above). Another crisis arose in 1916 over the sale of the Danish West Indies to the United States. Since 1918 Iceland has been a separate kingdom with the same king, with provisional arrangements for mutual privileges and co-operation. In 1920 the king's action in dismissing the government was held by socialists and others to be unconstitutional. A general strike was declared, and a republic talked of. A compromise was reached, however, with no greater change than an electoral reform, which extended proportional representation. Denmark's claim to the whole of Greenland was contested by Norway in 1921-22. The Stauning (Socialist) Government took office after an election in 1924.

See Carlsen, Olrik, and Starcke, *Le Danemarck* (1900); Harvey and Rappien, *Denmark and the Danes* (1915); Miss Thomas, *Denmark Past and Present* (1902); Miss Bröchner, *Danish Life in Town and Country* (1903); Rider Haggard, *Rural Denmark and its Lessons* (1911); F. C. Howe, *Denmark: A Co-operative Commonwealth* (1922). For the history, *Danmarks Riges Historie*, by several authors (1897-1905), Nisbet Bain's *Scandinavia* (1905), and Stefansson's *Denmark and Sweden* (1916).

**DANISH LANGUAGE AND LITERATURE.**—The Danish language has sprung from the south-eastern or Danish-Swedish branch of the *dōnsk tunga* (or *lingua danica*), which was the common name by which the language of all the Scandinavians was designated in the middle ages by the southern peoples of the Teutonic stock. From the 11th to the 13th century the Danish-Swedish branch of the old Scandinavian became more and more

markedly distinct from the Norwegian-Icelandic branch, through its replacing the old diphthongs with single long vowels, and dropping the initial *h* before *l*, *n*, and *r*; while the latter became characterised by a further modification of the *a* sound, by the loss of *v* before *r*, and by a series of contractions of consonants. In the provincial laws of the 12th and 13th centuries, which (after the Runic monuments) are the earliest specimens of this Danish-Swedish language, there are three dialects—that of Skaane (the southmost province of Sweden) and those of Zealand and Jutland, the first of which is nearest the old language, while the last two have deviated from it by dropping the final consonants from the old inflexional endings and changing their vowels *a*, *i*, *u* to a less distinct *e* or *æ*, retaining, however, the hard mutes *p*, *k*, *t* after vowels, as on the whole is still the case in Swedish and spoken Norwegian. The dialect of Zealand in the 14th and 15th centuries forms the foundation of modern Danish. The original vowels in almost all endings are there replaced by half-vowels, and the dental aspirate *p* by *t* or *d*; *p*, *k*, *t*, when following long vowels, are changed to *b*, *g*, *d*; masculine and feminine are merged in one common gender; nouns have no other case-ending than the possessive *s* for both numbers; verbs cease to indicate person (except in the imperative); and the singular number begins to supersede the plural, as it does everywhere in the spoken language from the 16th century. Danish, like Swedish, retains the suffixed definite article, which is characteristic of the Scandinavian languages. Its form is *-et* in the neuter, *-en* in the common gender, and *-ne* in the plural of both.

The influence of the Hanseatic League and the Oldenburg dynasty (from 1448) brought in a great number of Low-German words, especially relating to navigation and trade; while that of the order of St Bridget contributed a considerable Swedish element. In the first half of the 16th century the Danish language was chiefly used by religious writers, and the translation of the Bible (1550) is the first important monument of modern Danish. After this period Latin became once more the language of learning and culture, and for a century and a half there was no Danish writer of eminence. The influence of French was predominant in the 17th century, and that of High-German, which had been constant since the Reformation, culminated in the 18th century under the Struensee administration, when it was the language of government and public instruction. The result is, that Danish is indebted to German for fully one-third of its vocabulary. It was not till Holberg that the Danish written language began to be enriched from the stores of native expression in the spoken tongue. From the end of the 18th century revived study of Old Scandinavian and the development of a national poetic literature unfolded the language in a hitherto unsuspected richness and fullness, and since that time Danish prose has to a considerable extent worked itself out of its poverty and dependence. Danish is the softest of the Scandinavian languages, though less euphonious than Swedish. It is the language of the educated class in Norway, where it is considerably augmented from the native dialect, and is spoken with a somewhat harder pronunciation.

*Literature.*—After the Danish dialect had gradually separated itself from the Old Scandinavian as a softer and simpler speech, with a strong infusion of German ingredients, it was little used in writing down to the time of the Reformation. Saxo Grammaticus (i.e. 'the learned') in the second half of the 12th century wrote in Latin his *Historia Danica*, the only literary production of

medieval Denmark that retains any interest. The earliest writings in Danish are the church laws of Skaane (1162) and Zealand (1170), and the civil laws of Skaane (1160), Zealand (1170), and Jutland (1241); and after these a number of chronicles, partly in verse, of which the best known is the *Rimkrønike*, which was the first Danish book printed (in 1495). It is essentially an abridgment of Saxo. The famous Danish ballads called *Kæmpeviser* ('hero-songs'), some of which are said to belong to the latter part of the 11th century, were handed down orally from generation to generation, and were first collected, to the number of 100, by A. S. Vedel in 1591. In 1695 Peder Syv published a new edition with 100 more, and in 1812-14 appeared a selection of 222, edited by Abrahamson, Nyerup, and Rahbek. The fullest collection is in Svend Grundtvig's *Gamle Folkeviser* (1853-91; completed by Olrik). They are about 500 in number, and treat of the adventures of heroes, love, enchantment, spectres, and historical events. Doubtless they were sung to the dance, as is still the case in the Farø Islands. They must have suffered much by their not being written down till the 16th and 17th centuries.

The Reformation only emancipated Danish culture from Latin to bind it fast to German, which at the death of Frederick I. in 1533 was the language of the upper classes. About that time Christian Pedersen set up a printing-press at Malmo, at which he published a great number of popular books, and finally in 1550 the first complete translation of the Bible. Pedersen (1480-1554) is justly called the father of Danish literature. The hymns and translations of the Psalms by his contemporary Tausen (1494-1561), as also by Kingo (1634-1703), Vormondsen (1491-1531), and Arnebo (1587-1637), and the national history (10 vols. Copenhagen, 1595-1604) of Hvittfeld (1549-1609) were well received; but the Danish language was still banished from higher society till the advent of the Norwegian Holberg (1684-1754), the founder of Danish comedy. He found Denmark on the point of being absorbed in Germany. 'The common people,' he says, 'had no histories but dry lists of dates; no poetry but congratulatory verses; no theology but homilies and funeral sermons; and for plays, nothing but old stories about Adam and Eve.' He wrote histories of Denmark, of the Jews, and of the Church; and the irresistible humour of his comedies and satires covered with ridicule the imitators of foreign speech and manners. What Holberg did for Danish prose, another Norwegian, Tullin (1728-65), did for Danish poetry. Equally dissatisfied with the current imitations of the 17th century court-poetry of France, and with the poetic reform of Klopstock (at Copenhagen from 1751), Tullin followed the guidance of the English poets Pope, Young, and Thomson, and in this was followed by most of his countrymen who were settled at Copenhagen, while the Danes clung to German models. Ewald (1743-81), an ardent disciple of Klopstock, was Denmark's first great lyric poet and tragic dramatist. His verse shows an unsurpassed mastery of form, and is expressed in pure, clear, and noble language. Wessel (1742-85), by his 'tragedy,' *Love without Stockings* (1772), a humorous parody of the Danish imitations of the classical French drama, succeeded in laughing them off the stage. Nordahl Brun (1745-1816), preacher and poet, Claus Frimann (1746-1829), 'the Burns of the Norwegians,' Claus Fasting (1746-91), Jonas Rein (1760-1821), Jens Zetlitz (1761-1821), and others, formed themselves (1772) into a 'Norwegian Society' at Copenhagen, under the leadership of Wessel. It was the literary manifestation

of the Norwegian aspiration to separate nationality, which afterwards led to the foundation of the university of Christiania in 1811. From the death of Wessel in 1785 to the beginning of the present century the literature became entangled in rationalistic and political polemics, and produced little that is noteworthy. Its chief writers were P. A. Heiberg (1758-1841) and Malte Konrad Brun (1775-1826), both of whom were driven into exile in 1799-1800, the latter afterwards famous as a geographer; the critic Rahbek (1760-1830); the dramatists Samsø (1759-96) and Sander (1756-1819); and the lyricist Thaarup (1749-1821).

The poet and humorist Baggesen (1764-1826) forms the link between the 18th century and the early part of the 19th, when Danish literature took an entirely new departure, partly owing to the study of Kant, Fichte, and Schelling, and the influence of Schelling's follower Steffens (1773-1845); partly also to the strict censorship of the press in force from the year 1799. The educated classes turned from their controversies on points of literary criticism and theology to scientific inquiry; and the people, whose national feeling had been aroused by the French Revolution, by the share of Denmark in the Napoleonic wars, and especially by the events of 1801 and 1807, the war with Sweden (1808), and the loss of Norway (1814), welcomed with enthusiasm the rise of a new school, led by the romantic poet Oehlenschläger (1779-1850), who was equally distinguished as a lyrical and dramatic writer, and is still regarded by many as the greatest Danish poet. Contemporary with him were the poets Schack-Staffeldt (1769-1826) and Grundtvig (1783-1872), afterwards more eminent as a theologian; Ingemann (1789-1862), long the most popular novelist of Denmark; J. L. Heiberg (1791-1860), director of the royal theatre at Copenhagen, writer of numerous vaudevilles, and of the still popular national play, *Elves' Hill* (1823); Hauch (1790-1872), dramatist, novelist, and critic; and Blicher (1782-1848), who in his tales of Jutland was the first worker in the field which has since been cultivated in Switzerland and Germany by Jeremias Gotthelf and Berthold Auerbach. Of the other novelists of this period the chief are Blosbøll (1816-1900); Fru Gyllenbourg-Ehrensvard (1773-1856), mother of J. L. Heiberg; Saint-Aubain, or 'Karl Bernhard' (1798-1865); and the still more popular Winther (1796-1876), the charming poet of Danish country life. Herz (1798-1870), from the time when his *Ghost Letters* (1830) surprised the public with a poetic revival of the muse of Baggesen, now with his lyric poems, now with his tales, now in romantic and national tragedies, now in comedies and light vaudevilles, provided his countrymen with artistic and attractive works. Overskou (1798-1874) was a skilful dramatist, and Hostrup (1818-92) a popular author of comedies. All these writers are surpassed by Hans Christian Andersen (1805-75), whose wonderful stories are known throughout the civilised world. Less popular, but more profound, was the versatile writer Fr. Paludan-Müller (1809-76), who from his play *Love at Court* (1832) to his great epic poem *Adam Homo* (1841-48) wooed all the muses in succession. Here may be mentioned Bergsøe (1835-1911), writer of novels and popular works on scientific subjects; Goldschmidt (1819-87), editor of the influential democratic journals, *The Corsair*, *North and South*, and *Home and Abroad*, and afterwards author of numerous romances; Holst (1811-93), a writer of pleasing lyrics and tales; Kaalund (1818-85), with his two collections of poems, *A Spring* and *An Autumn*; the erotic and piquant and sometimes frivolous song-writer Aarestrup (1800-56); and Lembeke (1815-97), the translator of Shakespeare.

A great impulse was given to all branches of science from the beginning of the 19th century. The leading theologians were Grundtvig, the enthusiastic champion of the faith of his fathers against rationalism, and advocate of a union of the Scandinavian kingdoms, but with the church separated from the state; Mynster (1775-1850), Bishop of Zealand; Clausen (1793-1877), the disciple of Schleiermacher, and theological opponent of Grundtvig; Martensen (1808-84), Bishop of Zealand, and author of standard works on systematic theology and ethics; and Kierkegaard (1813-55), the most original thinker of Denmark. The chief exponents of philosophy were Sibbern (1785-1872), Nielsen (1809-84), and Brochner (1820-76); and in natural science the greatest names have been those of Oersted (1777-1851), the discoverer of electro-magnetism, the botanist Schouw (1789-1852), the geologist and chemist Forchhammer (1794-1864), the zoologist and archæologist Steenstrup (1813-98), and the physicist Niels Bohr. Much has been done for the study of Scandinavian antiquity by the *Sagabibliothek* of Müller (1776-1834), and the researches of Finn Magnusson (1791-1846) in mythology, and of Thomsen (1785-1865), Worsaae (1821-85), and Sophus Müller in archæology. The chief 19th-century writers of national history were Werlauff (1781-1871), Molbech (1783-1857), Allen (1811-77), Schiern (1816-82), and K. P. Paludan-Müller (1805-82); and of the history of the national literature and language, Petersen (1781-1862). In philology, Rask (1787-1831) and Madvig (1804-86), Nyrop (b. 1858) and Otto Jespersen (b. 1860), have a European fame.

About 1850 the enthusiasm for the national past, which had been excited by Oehlenschläger in Denmark, and by Tegnér, Geijer, and others in Sweden, together with the hatred of Germany aroused by the war of 1848-50, rose to a pitch of fanaticism. 'The northern force which had controlled the world' was extolled by Ploug and others as 'the only means whereby the victory of the Cause of Humanity could be achieved.' After Ploug (1813-94) the chief exponents of this great historic mission of the northern kingdoms were C. K. F. Molbech (1821-88), a euphonious lyricist and skilful dramatist, and translator of Dante; and Erik Bøgh (1822-99), a fertile writer of *feuilletons* and adapter of plays. A cosmopolitan reaction set in about 1870, led by Georg Brandes (b. 1842), who proved in his lectures on literature that Denmark was only a side-chapel in the temple of European thought and art, and that this overstrained 'Scandinavianism' was but the northern phase of the reaction from the tendencies of the 18th century, which had been experienced in England, France, and Germany many years before. Brandes withdrew to Berlin for some years from the storm of popular opposition. Not only in Denmark, but in Norway and Sweden also, his followers are now the prevailing party. The most conspicuous of these have been Jacobsen (1847-85), translator of Darwin and author of *Mogens* (1872) and other novels, and (till in 1883 he became Conservative) Holger Drachmann (1846-1908). Other noteworthy writers are Schandorph (1836-1901), equally happy in his sketches of the Zealand peasant and the Copenhagen snob; the versatile writer Hermann Bang (1858-1912); and the dramatist Edvard Brandes (b. 1847), brother of Georg Brandes. The novels of Johannes Buchholtz and Martin Andersen Nexø are well known outside of Denmark.

Of all the Scandinavians, the Danes have shown the greatest aptitude for the imitative arts, and their art is the most independent. While the painters of Norway have been mostly trained at

Düsseldorf, and the Swedes at Paris, the Danes have been especially attracted to Rome. The sculptor Thorwaldsen (q.v.) has left a great monument of his genius in the works contained in the Thorwaldsen Museum at Copenhagen. Of later artists may be mentioned the painters Marstrand, Carl Bloch, Exner, Kroyers, Henningsen, and Otto Bache. Of music, the chief composers in the 19th century were Hartmann, Gade, and Heise.

See Nyerup and Rahbek, *Den danske Digtekunsts Historie*, 4 vols. (1800-8), and *Udsigt over den danske Digtekunst under Frederik V. og Christian VII.* (1819-28); Nyerup and J. E. Kraft, *Almindeligt Litteraturlæxikon for Danmark, Norge og Island* (Copenhagen, 1818-20); Petersen, *Den danske Litteraturs Historie*, 6 vols. (1853-64); Overskou, *Den danske Skueplads i dens Historie* (1859-74); Andersen and Petersen, *Illustreret dansk litteraturhistorie* (1916 et seq.); G. Brandes, *Ludvig Holberg og hans Tid* (1884); the general treatises in Danish by Thorsens (1814; 6th ed. 1866), Heiberg (1831), Molbech (1839), Ström (1871), Erikson (Christiania, 1878), Winkel-Horn (1880), and Hansen (new ed. 1902); and in German by Strodtmann (1873), Wollheim de Fonseca (1874-77), and Winkel-Horn (1880); Gosse's *Studies in the Literature of Northern Europe* (1879), and his *Two Visits to Denmark* (1912); also the *Urford Book of Scandinavian Verse*, ed. Gosse and Craigie (1925).

**Dennery**, ADOLPHE PHILIPPE, a French dramatic writer of Jewish extraction, was born at Paris on June 17, 1811. At first clerk to a notary, he soon became a successful dramatist, and was so prolific that between 1831 and 1881 he produced, by himself or in concert with others, about two hundred miscellaneous pieces, including regular dramas, vaudevilles, and operatic texts. One of the most successful was the drama, *Marie Jeanne* (1845). He was the creator of the Norman watering place, Cabourg. He died 25th January 1899.

**Dennewitz**, a small village in the province of Brandenburg, Prussia, 42 miles SSW. of Berlin. Here was fought, on the 6th of September 1813, a battle in which 70,000 French, Saxons, and Poles, under Ney, were routed, after obstinate fighting, by 50,000 Prussians, under Bülow.

**Dennis**, JOHN, critic, was born in London in 1657, the son of a prosperous saddler. He had his education at Harrow, and Caius College, Cambridge, where he graduated B.A. in 1679. After a tour through France and Italy, he took his place among the wits and men of fashion, and brought a sufficiently rancorous pen to the assistance of the Whig party. His acquaintance with Dryden and Wycherley and other distinguished wits, as well as his native bent, made him a playwright. His plays had but little success. Of the nine, the two most famous were *Liberty Asserted* (1704) and *Appius and Virginia* (produced 1709). Pope's *Essay on Criticism* (1711) contained a contemptuous allusion to the latter, answered by Dennis next month in *Reflections, Critical and Satirical*, which was the commencement of a long and embittered feud between the poet and the critic. Pope's *Narrative of Dr Robert Norris, concerning the Strange and Deplorable Frenzy of John Dennis, an officer in the Custom-House* (1713), was a virulent, vulgar, and officious attack made on Addison's behalf, in which that genial author, through Steele, disavowed any complicity. Dennis was poor and blind during his last years. A few weeks after a theatrical performance, got up for his benefit by Pope and some others, he died, 6th January 1734. Dennis was embroiled in controversy all his life, and his naturally impatient temper became completely soured. He made many enemies, and his name, which his own writings could scarce preserve, will live for ever in their contempt and hate. He is one of the best-abused men in English literature. Swift lam-

pooned him, and Pope not only assailed him in the *Essay on Criticism*, but finally 'damned him to everlasting fame' in the *Dunciad*. Yet he was no fool, and his *Advancement and Reformation of Modern Poetry* (1701) and *The Grounds of Criticism in Poetry* (1704) will still repay perusal. 'Spite of the growling of poor old Dennis,' says Lowell, 'his sandy pedantry was not without an oasis of refreshing sound judgment here and there.'

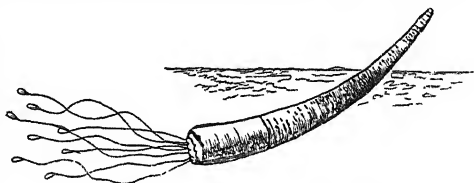

**Dénouement** (Fr. *dénouer*, 'to untie'), a French term naturalised in England, applied generally to the termination or catastrophe of a play or romance; but, more strictly speaking, to the train of circumstances solving the plot, and hastening the catastrophe.

**Dens**, PETER, a well-known Roman Catholic theologian, was born in 1690, at Boom, near Antwerp. Little is known of his early life; but from the epitaph on his tomb in the chapel of the archiepiscopal college of Malines, it appears that he was reader in theology at Malines for twelve years, *plebanus* or parish priest of St Rumold's, and president of the College of Malines for forty years. He died 15th February 1773, in the eighty-fifth year of his age. The work which has rendered Dens's name familiar, even to the Protestant public, is his *Theologia Moralis et Dogmatica*. It is a systematic exposition and defence—in the form of a catechism—of every point of ethics and doctrine maintained by Roman Catholics, and is extensively adopted as the text-book of theology in their colleges. It appears to owe its popularity more to its being a handy and usable compilation than to any great talent exhibited by its author. The casuistical parts of the work have been severely criticised by Protestant moralists. An edition was published at Dublin in 1832.

**Density**. See SPECIFIC DENSITY.

**Dental Formula**. See TEETH.

**Dentalium** (Lat. *dens*, 'a tooth'), or Elephant's Tusk Shell, a remarkable genus of molluscs, type of a small class called Scaphopoda. The shell is tubular, like an elephant's tusk, open at both ends, and lined by an almost completely tubular 'mantle.'

Dentalium, in natural position in sand.

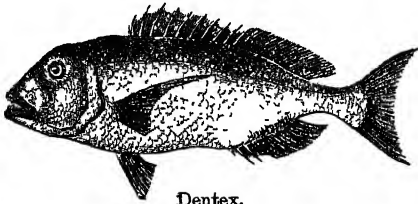

The animal has an indistinct cylindrical head with a mouth at its extremity, surrounded by a circle of tentacles. Two pads at the base of the head and above the foot bear ciliated contractile filaments, possibly respiratory. The 'foot' is long and divided into three at the end. The mouth includes a rasper. There are no eyes, but an ear-sac is present. Neither heart nor gills are developed. The sexes are similar and separate. The larva is ciliated and free-swimming. The type is of much zoological interest, but its affinities are still uncertain. The animal lives with the anterior end plunged into the sand on the sea-coast, at depths of ten to a hundred fathoms. By means of the foot they can creep slowly. They feed on minute animals, and have an almost cosmopolitan distribution. The class includes two or more other genera. *D. entale* occurs off British coasts; and about forty living species are known. The genus occurs as a fossil from Carboniferous strata (or

perhaps earlier) onwards. The shells are used for currency and for ornament by the Indians of the northern Pacific coast of America.

**Dentaria**, or CORAL-ROOT (both names due to knobbed root-stock), is a small genus of Cruciferae, represented in Britain by the rare *D.* (or *Cardamine*) *bulbifera*, in which the upper leaves bear bulbils (see BULB), while the pods rarely ripen. The root-stock, being pungent, was formerly dried as a remedy for toothache. *C. diphylla*, a North American species, is called Pepper-root (q.v.) from the same property. The name Coral-root (q.v.) is also applied to the orchid *Corallorhiza*, while the true Toothwort (q.v.) is *Lathraea squamaria*.

**Dent du Midi**, a picturesque and imposing peak of the Alps of Valais, 10,450 feet high, on the frontiers of Savoy, 5 miles SW. of St Maurice in the lower valley of the Rhone. It is a conspicuous feature of the view from Lausanne and Montreux. The Aiguille du Midi is a peak (12,600 feet) of the Mont Blanc group.

**Dentex**, a genus of acanthopterous fishes near perches. One species (*D. vulgaris*), the Dentex of the ancient Romans, abounds in the Mediterranean,

Dentex.

and has occasionally been taken on the southern shores of Britain. It is an excessively voracious fish, with large sharp teeth, and attains a large size, sometimes three feet in length, and 20 to 30 pounds weight. Great numbers are taken in the mouths of rivers in Dalmatia and the Levant, where they are cut in pieces, and packed in barrels with vinegar and spices, just as the ancients used to treat them.

**Dentifrice.** See TEETH.

**Dentine**, or IVORY, the principal constituent of mammalian teeth. See TEETH.

**Dentistry.** The practice of dentistry is doubtless of great antiquity. Mention of teeth bound with gold occurs in the laws of the twelve tables (5th century B.C.). Modern dentistry, founded on rational practice, in accordance with scientific principles, and recent histological, bacteriological, and pathological research, owes its creation to the workers and investigators among its practitioners since the middle years of the nineteenth century. Previously little or nothing was known of the etiology of dental and oral conditions, the importance of a sepsis and antisepsis was not recognised, and treatment rested on an empirical rather than a scientific basis.

The art of the dentist applies itself to the care and treatment of the human teeth and the associated structures, and falls naturally into two divisions: operative dentistry or dental surgery, and mechanical dentistry or dental prosthesis.

Operative dentistry deals with (1) preventive or prophylactic measures; (2) remedial or curative measures. Prophylaxis begins even before the birth of a child, with the instruction of the mother in the care of her own health, and the adoption of a suitable diet. The young child must be prevented from forming such habits as thumb-sucking, and the use of 'comforters' must be prohibited, as they cause deformities of the jaws and malpositions of

the teeth. The diet should contain a sufficient proportion of the calcium salts and of the vitamins requisite for the calcification and growth of the developing teeth. After the teeth are cut attention to their cleanliness is essential, and cannot be begun too soon. It is advised that the meals of children should end with food of a fibrous consistency—e.g. a piece of apple—which demands mastication, and cleanses the teeth, rather than with soft pappy puddings, which stagnate and decompose on the surfaces and interstices of the teeth. Some occupations involve danger to the teeth and jaws, and in the case of match-makers and other workers with phosphorus legislation has made prophylactic measures imperative.

Remedial or curative measures are called for in the following conditions: caries or decay of the teeth, odontalgia or toothache, neuralgia, erosion, abrasion, fracture, injury, or dislocation of teeth; exposure, inflammation, irritation, hyperplasia, degeneration, sepsis and necrosis of the pulp or nerve of a tooth; inflammation or injury of the dental periosteum, alveolar abscess, alveolar necrosis, inflammation, suppuration, or ulceration of the gums or mucous membrane of the mouth or tongue; periostitis of the jaw, necrosis of the jaw, exostosis of roots of teeth, pulp-stones, absorption of roots; malposition or irregularity of teeth, supernumerary teeth, non-erupted teeth, tumours or growths in connection with the teeth, especially odontomes, which are regarded as aberrations of development, salivary calculus or tartar, pyorrhoea alveolaris (a chronic purulent discharge from the sockets), abscess or empyema of the maxillary sinus, dislocation or fracture of the jaw.

Of all these conditions caries, or decay of the teeth, is by far the most prevalent, and that which makes the most frequent call on the services of the dentist. Inspection of the teeth of school children in the elementary schools reveals an appalling state of affairs in this respect; in some districts not more than 10 per cent. to 20 per cent. of the children are found to be exempt. The institution of school dental clinics will, it is hoped, do something to cope with this widespread defect, and may greatly improve the health of the children. In the treatment of caries the dentist either attempts to remove and arrest the decay, and to supply the place of the destroyed tissue by a filling or stopping, or, if that be impossible, he extracts the tooth.

In the production of caries there are two stages. The first is the solution of the enamel by acids produced in the mouth as the result of fermentation of debris of food. The bread of to-day, made from flour ground to an impalpable powder, having hardly any crust, underfired, eaten fresh from the oven, and containing so much water that it forms a paste in the mouth, which is bolted without proper mastication and admixture with saliva, furnishes a sticky, slimy mass, which adheres to the teeth with great tenacity, and rapidly undergoes lactic acid fermentation. This bread, along with the excessive use of sugar, must be blamed for the general prevalence of caries in civilised communities. Once the dentine which forms the bulk of the tooth is exposed by the solution of the enamel, bacteria gain an entrance, they multiply with great rapidity in an environment so favourable, the dentine is destroyed, and a cavity of decay is formed. The *stopping* or *filling* of such cavities constitutes the bulk of the dentist's work, and requires great delicacy and skill. The preparation of the cavity is of prime importance. It must first be opened up so as to get free access. All affected or overhanging enamel is cut away with enamel chisels, or by means of burs, which are small rotary files rapidly revolved in a suitable hand-piece of the dental engine, driven either by the foot or by an electric motor. All decayed or decaying

dentine is cleared away; for this purpose slender steel instruments, called excavators, are used. They are of such varied shapes as to permit all parts of any cavity in any tooth to be reached. These are supplemented by burs and stones in the dental engine. When performed by a skilful hand, and with sharp instruments, little or no pain may be felt during this process; but if the dentine is sensitive, 'obtusendents,' such as carbolic acid, oil of cloves, eugenol, or desiccation with alcohol and hot air may be used to diminish the sensitivity. If the pulp is exposed, or if the decay approaches it so nearly as not to leave a sufficient layer of sound dentine to protect it from pressure, heat, or cold, the 'nerve' or pulp must be killed. Devitalisation of the pulp may be effected by sealing in a small quantity of arsenious acid and cocaine for twenty-four to forty-eight hours, or by paralyzing it with cocaine in solution, applied under pressure. The pulp, when devitalised, is removed by special barbed instruments called nerve-extractors or nerve-bristles, and the pulp-chamber and root-canals, having been cleaned and sterilised, are filled with an antiseptic substance, such as wax impregnated with iodoform or trikresol-formalin paste. In stopping a cavity the objects are to remove all decay, to sterilise the prepared cavity, and to fill it with a sterile substance which will take the place of the tissues decayed and removed, will prevent the recurrence of decay, and will restore the tooth to functional activity. The ideal filling substance would be easy of introduction, undistinguishable from the natural tooth, absolutely resistant to the action of such chemical or mechanical agencies as it is exposed to in the mouth, and a non-conductor of thermal or electrical stimuli. Such a material has yet to be found. During the insertion of a filling moisture must be excluded, as unless this be done the cavity cannot be sterilised, nor can its sterility be maintained. The best means is by the adjustment of the rubber-dam; the tooth to be filled and the teeth adjoining it are passed through holes punched in a sheet of thin india-rubber, which is held in place by waxed silk ligatures tied round the necks of the teeth, or by specially devised clamps. The saliva which gathers in the mouth is drawn off by a saliva-ejector, in the form of a Sprengel pump worked by a minute water-tap. Another saliva-ejector has a compressible rubber bulb which the patient manipulates. Dexterous operators sometimes dispense with the rubber-dam for short operations, and rely on aseptic napkins, or cotton-wool rolls, to exclude moisture. The cavity being properly shaped, excavated, sterilised, and dry, the filling is inserted. The method varies with the material.

**Gold.**—The gold used is chemically pure, it is in the form of foil, either in sheets, or rolled round a broach and cut in short lengths to form loosely rolled cylinders. It is also prepared folded into square pellets, and in that peculiar form known as sponge-gold or crystal gold. Various modes of packing the gold are adopted, according as the gold is cohesive, when advantage is taken of the fact that it welds at ordinary temperatures, or non-cohesive. In the latter case the cavity must be of such a shape as to retain the filling, which is made by tightly wedging the gold so that it forms a homogeneous mass with absolutely watertight adaptation to the walls of the cavity. Cohesive gold can be adapted to a cavity of any shape, provided that small portions are first of all tightly fixed in small pits, slots, or recesses made in the floor of the cavity. To the gold fixed in these 'retention points' small successive portions are welded till the cavity is full. Gold-pluggers are used for welding and condensing cohesive gold, which must be further condensed by an automatic

mallet, an instrument which is run in the dental engine, and gives a succession of blows the force of which can be regulated. Where the placing of retention points presents difficulty, the cavity may be partly filled with cement, into which crystal or sponge-gold is pressed. The filling is then built up in the usual way after the cement has hardened. In any case, the filling when completed must be trimmed, polished, and burnished, by means of finishing-burs, stones, discs, wooden points, felt cones, abrasive strips, polishing powders, and burnishers.

**Amalgam.**—An amalgam is a combination of two or more metals, one of which is mercury, and the utility of dental amalgam alloys depends upon the property possessed by mercury of dissolving other metals to form compounds which in a short time harden or set. The dental alloys most in favour contain silver, tin, copper, and zinc. The alloy is cut into fine filings or shavings, and rubbed in a mortar with mercury sufficient to make a paste. This paste is inserted into the cavity while plastic, packed with blunt-ended instruments, and allowed to set hard. A widely adopted practice is the lining of cavities with cement into which, while still soft, amalgam is pressed, thus producing a combination filling with the adhesive property of the cement, and the strength and durability of the amalgam. By this method the discoloration of the tooth attendant on the use of amalgam alone is avoided.

**Cements.**—These are largely used on account of their adhesive properties, and because they are more sightly in the front of the mouth than metal fillings. They comprise the oxychloride cement, and the three classes of oxyphosphates. All consist of a powder and a liquid, which are mixed with a spatula on a glass or porcelain slab to a consistency varying from cream to putty-like, and must be put into the cavity without much delay, as they set quickly. In the oxychloride cement the powder is calcined zinc oxide, the liquid is zinc chloride. The three classes of oxyphosphates are: (1) basic zinc phosphates, in which the powder is zinc oxide plus colouring matter, the fluid is glacial phosphoric acid; (2) oxyphosphates of copper, in which oxide of copper instead of zinc forms the powder; (3) silicate cements, so called. These contain in the powder silicon and oxides of other metals than zinc, such as beryllium, aluminium, and calcium. The liquid is phosphoric acid, modified by the addition of other constituents, such as zinc phosphate and aluminium phosphate. These 'silicate' or translucent cements lack to some extent the adhesive properties of the basic zinc phosphates; per contra, they approach very closely in appearance and lustre to the natural enamel. In most mouths cements tend to undergo solution and disintegration, and usually require renewal from time to time.

**Gutta-percha.**—The juice of the *Isonandra Gutta*, dried, purified, and afterwards mixed with zinc oxide, or zinc oxide and mercuric sulphide, to form the white or pink varieties, is largely used for temporary stoppings. It is softened and made plastic by dry heat, and inserted warm. It is soluble in chloroform and in eucalyptus and cajuput oils; a solution is used for filling root-canals and for setting crowns and bridges.

**Tin,** in the form of foil, is used in the same manner as non-cohesive gold. Large cavities may be partly filled with tin and finished with cohesive gold. Tin may also be used in combination with gold to make a 'tin-gold' filling, a sheet of tin-foil being sandwiched between two sheets of gold-foil, or a sheet of tin and one of gold may be rolled together. The combination gives a hard and durable filling.

**Inlays.**—These may be made of either porcelain

or metal; the inlay is prepared to fit exactly the prepared cavity into which it is cemented. Some operators insert ready-made inlays of standard sizes, by cutting the cavity with special trephines and burs to fit the inlay; but the generally adopted procedure is to shape the cavity so that an impression can be taken of it, or that a matrix adapted to its walls and margins can be withdrawn without distortion. For porcelain inlays a matrix is essential. It may be of platinum or of gold, according to the high or low fusing-point of the porcelain body used. A matrix giving an exact reproduction of the shape of the cavity having been secured, either direct from the cavity, or by swaging in a plaster or metal model thereof, the porcelain body, mixed with water or alcohol, is put in the matrix and baked in an electric furnace. Several bakings, and gradual additions of porcelain body till the inlay is built up to the required shape, will be needed. In the preliminary bakings the body should be 'biscuitted' only; not till the final baking should it be glazed. When finished the inlay must be grooved on its inner surface with diamond discs or etched with hydrofluoric acid to afford retention to the cement that fixes it in place.

Metal inlays are made either of gold or of alloys specially prepared for the purpose. The *cire perdue* process is that generally employed. A wax model of the proposed inlay is made either direct from the cavity or from a model of it. This has a sprue wire attached to it and is invested in a mixture of plaster of Paris and other materials in a casting flask or ring. When the investment has set hard the sprue wire is removed, leaving the channel by which the molten gold or other metal is introduced after the wax has been dispersed by heat. The melted metal is forced into the mould in various ways by casting machines. Some use superheated steam to propel the metal by direct pressure, some depend on suction by the production of a vacuum in the mould, others on centrifugal force. Metal inlays can also be made by melting the metal in a platinum or gold matrix.

**Extraction of Teeth.**—The instruments used are forceps and elevators. A formidable and unscientific tool called the 'key' was once in great favour, but fortunately it has fallen into disuse. Hundreds of different shapes and sizes of forceps have been designed by misguided ingenuity, but the skilful operator needs very few; indeed, the Edinburgh School teaches that two pairs of forceps are all-sufficient. The principal points to observe in the operation are: that the blades of the forceps should be sharp, that they should be capable of embracing accurately the root or roots of the tooth to be extracted, that the root or roots should be firmly grasped by the forceps, that the operator should take a firm grip of the margins of the jaw at the site of the tooth to be extracted, with the finger and thumb of the left hand, and that the extractive force should be applied in the direction of least resistance, and in such a manner as to produce the least possible fracture, laceration, or disturbance of the parts. Teeth with conical roots—viz. the upper incisors and, to a varying degree, the canines—should be rotated; all others should be carried outwards, unless they are so abnormal in form and situation as to render this impossible. In no case will a pulling force be found effectual. The elevator is used to turn out roots or teeth to which it is difficult or inconvenient to apply the forceps. All instruments used must be thoroughly cleaned and sterilised before and after use, and an antiseptic mouth-wash should be prescribed.

**Anæsthetics.**—Tooth extraction is extremely painful, and the use of anæsthetics during its performance is therefore often desirable. Nitrous oxide, or laughing-gas, as it is sometimes called,

is of all general anæsthetics that most frequently employed by dentists, and has by reason of its great safety enjoyed unbroken popularity. The mixture of nitrous oxide and oxygen has many advantages over nitrous oxide alone, and there is little doubt that with the advent of simplified apparatus for its administration, and more extended instruction in the method of using it, this combination, unsurpassed for its freedom from danger to life, or even unpleasant symptoms during induction and after recovery, will become the anæsthetic of choice for extractions. Nitrous oxide or nitric oxide and oxygen may be used in combination with a small dose of ethyl chloride (3 c.cm. should be regarded as the maximum), or with ether vapour if a very prolonged operation is anticipated. Chloroform is at once the most unsuitable and the most dangerous anæsthetic to use for a dental operation, and its use in this connection should be regarded as unjustifiable. Local anæsthetics have a sphere of usefulness in the extraction of single teeth. Cocaine, stovaine, novocaine, eucaine, alypin, and quinine with urea hydrochloride, are the analgesics most in favour. Solutions of these drugs are injected into the tissues in the neighbourhood of the tooth to be extracted, a local analgesia is produced, and a more or less 'painless extraction' is effected. Aseptic technique must be rigidly observed, and no injection anæsthesia should be practised when a septic condition of the parts already exists. The neglect of these precautions by the ignorant or careless operator entails the risk of blood-poisoning. Freezing the part involved by the rapid evaporation of ethyl chloride or ether spray is sometimes practised for the production of analgesia.

**Scaling.**—This is the removal of deposits of tartar from the teeth; the operation is effected with instruments called scalers. Deposits of tartar are termed salivary calculus or serumal calculus, according to their supposed deposition from solution in saliva or in the blood plasma. Tartar of either variety, wherever deposited, acts as an irritant, causing inflammation and absorption of the soft tissues, and rendering them susceptible to bacterial invasion and to the production of pyorrhœa alveolaris, which, if untreated, leads to the destruction of the sockets and loss of the teeth. Pyorrhœa alveolaris is one of the forms of oral sepsis which modern physicians regard as a frequent cause of pernicious anæmia and various toxæmias. The importance of removing deposits of tartar from the teeth must, therefore, be urged with insistence. The process is long and difficult, and its perfunctory performance is worse than useless. When pyorrhœa is established, careful scaling and the use of tartar solvents, with the application of stimulating and antiseptic substances, either locally or by the process of ionisation, may cure it. The use of autogenous vaccines is sometimes beneficial, sometimes disappointing. In many cases extraction of the teeth the sockets of which are affected is the only remedy.

**Regulation of Teeth, or Orthodontics.**—This is concerned with the correction of irregular positions of the teeth in the dental arches, leading to perversion of the normal relations of the occlusal surfaces of the teeth when the jaws are closed, or, in short, to mal-occlusion. Mouth-breathing, often due to adenoids, bad habits, as thumb-sucking, loss of the first permanent molars, and heredity are cited as frequent causes of irregularity and mal-occlusion. The correction of irregularity depends on the application of a continuous force or pressure exercised upon the teeth it is desired to move. Many devices have been invented. Of these Angle's Arch, with its adjunctive bands, ligatures, and levers, is, perhaps, the most commonly used, and the most useful. Other means, such as split expansion-plates,

traction-screws, jack-screws, spiral springs, wire springs, elastic bands, expansible wedges, inclined planes, &c., are occasionally utilised. After the mal-occlusion is corrected, which may take a considerable time, the teeth must be kept in their new positions by a retention apparatus, which may have to be worn for six months or longer.

*Radiography* is of great help to the dentist in showing the presence of unerupted teeth, abnormalities of roots, pulp-stones, absorption areas in chronic apical abscesses, cysts, new growths, fractures, and other diseased or abnormal conditions.

*The Treatment of Fractures and Dislocations of the Jaws* falls within the province of the dentist.

*Mechanical Dentistry, or Dental Prosthesis*, deals with (1) the construction and adaptation of artificial substitutes for teeth which have been removed, shed, or lost, by operation, injury, disease, or accident; (2) crown and bridge work, in which one or more artificial crowns are inserted in the mouth, supported by sound remaining teeth or roots; (3) the making of obturators for the closure of congenital cleft palate or of perforations of the palate; (4) the replacement by artificial appliances of parts of the jaws or face removed by operation or destroyed by accident or disease.

In the great majority of cases artificial teeth are mounted on plates of metal or vulcanite. These plates are retained in the mouth by reason of their accurate fit and atmospheric pressure—these are the so-called 'suction' plates; by clasps or bands fitted round sound remaining teeth; or sometimes by gold spiral springs. The teeth themselves are made of a high-fusing porcelain, and are obtainable of every conceivable size, shape, and shade. Diatoric teeth, which are suitable only for vulcanite plates, have in their substance holes or undercut cavities, on which they depend for their retention in the vulcanite. Pin teeth, which are available for either metal or vulcanite plates, have two platinum pins baked into their lingual aspect. Pin teeth are also made with gold pins, or with base metal pins. Tube teeth have a platinum tube baked lengthwise in the middle of the tooth. Gum blocks have an artificial gum of porcelain. Special teeth are made for what is known as continuous gum work. Here platinum forms the base on which the set of teeth is built up with porcelain body, which, when baked in an electric furnace, closely simulates the appearance of the natural gum and palate.

Before artificial teeth can be inserted with safety and comfort, the mouth and any remaining teeth must be put in a healthy and hygienic state. Loose, useless, or very badly decayed teeth should be extracted, also any roots that are not crowned; all stoppings that are required must be done, and the remaining teeth scaled and cleaned.

The making of a set entails (1) taking an impression of the jaws with plaster of Paris or modelling compound, and casting plaster models from the moulds so obtained; (2) taking the bite—i.e. getting the relative positions of the upper and lower jaws in closure, and fixing the models in that relationship on an articulator; (3) setting up the case—i.e. assembling the teeth selected in the exact positions they are to occupy in the finished case; (4) trying in, and finally adjusting the trial set; (5) finishing. If the case is to be of vulcanite, the model and wax set are invested in plaster in a specially devised two-part flask; the flask is opened, the wax scalded out, and replaced by dental rubber; the flask is closed, heated, pressed, and clamped. The case is now vulcanised by superheated steam under pressure, and when cold taken out of the flask, filed up, smoothed, and polished. When the plate is of gold or other metal it may be either cast or 'struck.' In the

first case the set is made up as if for vulcanite, is invested in a special casting ring; by means of sprues, channels are left for molten metal to flow into the mould left by the burning off of the wax. The metal, usually gold, is driven into the mould by steam pressure, or by the production of a vacuum in the mould. Several ingenious casting machines have been devised to accomplish this process. More generally the plate is 'struck.' The original model is duplicated in gun-metal or zinc; this is the 'die,' and from it a 'counter die' is taken in tin or lead. The plate, cut to pattern, is swaged between the die and counter, being stamped out, as it were, on an anvil or block with a heavy swaging-hammer. It is trimmed, and any bands or clasps fitted and soldered. The teeth are now fitted to the plate. The mode of attachment varies. Tube teeth are fixed by a pin soldered to the plate and passing up the tube. Pin teeth are backed with gold plate soldered to the pins, and the backing is soldered to the plate.

*Crowning* is the adaptation of an artificial crown to a root. A crown is fastened to a root either by means of a dowel-post or pin of gold, platinum-iridium, or other suitable metal cemented into the root, which is drilled out for the reception of the post, or by means of a collar of like material closely embracing the root. Crowns for the front teeth should be either all porcelain or porcelain-faced; for back teeth hollow shell crowns of gold are often used. It is essential that the root to be crowned should be absolutely healthy.

In *Bridge-work* sound, healthy teeth or roots are used as the piers to carry a bridge bearing artificial teeth across spaces from which teeth are absent. The piers may be crowned, so that hollow crowns on the bridge slip over them; they may have tubes cemented into them to receive split-pins fixed to the bridge, or many other clever devices may be employed. Bridge-work should be removable, as it is impossible to keep a fixed bridge clean, and its wearer has always an unhealthy mouth and a foul breath.

*Laws as to Dentistry.*—The Dentists Act, 1878, established the Dentists' Register. To the Register were admitted those in practice before the passing of the act, and those who, before or after its passage, obtained a diploma or licence in dental surgery from one of the Royal Colleges of Surgeons, a British university, or other examining body recognised for the purpose by the General Medical Council. The curriculum is laid down by the council, and extends over a period of four years. The 1878 Act enabled the public to distinguish between qualified and unqualified practitioners of dentistry by restricting the use of the titles 'dentist' and 'dental practitioner' to those on the Dentists' Register or the Medical Register. It did not limit or prohibit practice by the unqualified or the assumption by them of misleading titles. Recognition of the evils of unqualified practice, with its attendant dangers to the public, led to the passage of the Dentists Act, 1921. This act, following the lead of most of our colonies and dominions, prohibits the practice of dentistry by unregistered persons, sets up a Dental Board of the United Kingdom to administer the act, and provides for the admission to the Register, under specified conditions as to age, character, and length of time in practice, of present unqualified practitioners.

The literature is voluminous; a few of the best-known books are: *The Science and Practice of Dental Surgery*, edited by N. G. Bennett; *Diseases and Injuries of the Teeth*, by Smale and Colyer; *Dental Surgery*, by Sewill and England; *Text-book of Operative Dentistry*, by Kirk; *Dental Surgery*, by Tomes; *Extraction of Teeth*, by Gibbs; *Text-book of Prosthetic Dentistry*, by Essig and Turner; *Mechanical Practice in Dentistry*, by Booth

Pearsal; *The Dental Laboratory, &c.*, by Rose; *Malocclusion of the Teeth*, by Angle; *Operative Dentistry*, by Black; *Dental Metallurgy*, by Essig and Koenig. Periodicals are the *British Dental Journal*, *British Journal of Dental Science*, *Dental Record*, *Dental Cosmos*.

**Dentition.** See TEETH, TEETHING, HORSE.

**Denton**, a manufacturing and coal-mining town and urban district of Lancashire, 4 miles NNE of Stockport. Reservoirs of the Manchester water-works are near the town. Pop. 18,000.

**D'Entrecasteaux Islands**, since 1884 part of British New Guinea (Papua), lie north of the south-eastern extremity of New Guinea. With an area of 1200 sq. m., they comprise three chief islands separated by narrow channels. They are named after the French admiral and explorer, Bruni D'Entrecasteaux (1739-93), who visited these waters in 1792. His name is also preserved in D'ENTRECASTEAUX POINT on the south-west coast of Western Australia; and in D'ENTRECASTEAUX CHANNEL, separating the south of Tasmania from Bruni Island.

**Denudation**, in Geology, means the laying bare of underlying rocks by the removal of superficial matter, and also the process by which the earth's surface is broken up and the loose material carried away. The more important agents of denudation are wind, rain, running water (springs, underground streams, brooks, and rivers), frost, snow, ice (glaciers), the sea (waves, breakers, currents), plants, and animals. The action of wind is seen in the erosion of rocks produced by the sand and grit which in certain dry regions is swept by the winds against projecting rocks, an action often resulting in the undermining of cliffs and the downfall of rock-masses. The sand produced by the superficial disintegration of rocks is carried forward and heaped up in the form of dunes or sandhills (see DRIFT). Rain is also a potent agent of denudation, its action being both chemical and mechanical. Rocks are more or less altered and decayed, and the decomposed materials carried off in solution by rain-water. The more soluble rocks, such as rock-salt, gypsum, and limestone, readily succumb, but there are very few rocks indeed which are not more or less acted upon chemically by rain. So that in many places the rocks are thus 'weathered' to considerable depths, the decomposed crusts varying in thickness from a mere line up to many feet or even yards. The mechanical action of rain consists chiefly in the sweeping away of this disintegrated material, which often accumulates in hollows, forming what is called *rain-wash*. Running water acts also chemically and mechanically. Thus, the rain that sinks underground and rises to the surface again in springs, brings about many changes in rocks. Immense quantities of mineral matter are brought up in solution, and thus, in time, underground cavities are formed, especially in the more soluble rocks. In regions of calcareous rocks, the whole drainage is sometimes conducted underground, the ingulfed streams and rivers acting both chemically and mechanically, and giving rise to a large series of subterranean tunnels (see CAVES). The action of underground water often brings about local subsidences, falls of rock, and great landslips. The denuding action of superficial terrestrial waters is seen in the excavation of gullies, ravines, and river-valleys, one of the most remarkable examples of river erosion being the Grand Cañon of the Colorado (q.v.), which is a chasm nearly 400 miles long, with approximately vertical walls rising to a height of 4000 to 7000 feet above the bed of the river.

Frost acts with great intensity at high levels and in high latitudes, but even in temperate regions its action is very marked and productive of great disin-

tegration of rocks. Indeed, in the production of the weathered crusts of rocks, frost is hardly less active than rain. It is in arctic and mountainous countries, however, that its action is most conspicuous. The rocks under its influence are ruptured and shattered to such a degree that frequently the parent rock-masses become buried under shivered heaps of their own debris. Glaciers are likewise powerful denuding agents. They are not only instrumental in transporting the rock-rubbish which is showered down upon them from overhanging cliffs, &c. (see BOULDERS), but by means of the blocks and debris which they drag forward on their beds, they grind, furrow, and smooth the rocks over which they flow. The peculiarly muddy character of the water that escapes from the terminal front of a glacier shows how powerful this erosive action must be, for the mud carried in suspension is simply the fine flour of the rocks which has resulted from the grinding action. The sea, again, acts like a great horizontal saw, which is continually rasping away the rocks along the coast. Cliffs are in this way undermined, rock-falls take place, and the tumbled rock-masses are by-and-by pounded down into shingle, gravel, and sand, which are hurled by the waves against the cliffs, and thus ere long the latter are again undermined, and further rock-falls take place.

The chief denuding agents have now been mentioned, but the destructive action of plants and animals cannot be ignored. Thus plants aid in the demolition of rocks by sending their roots into rock-crevices and wedging the masses asunder, and hence they aid the freer percolation of water, and prepare the way for the better action of frost. Vegetation also, by attracting rain, tends to increase the flow and erosive action of streams and rivers, while its decomposition yields to rain those organic acids which so greatly increase the chemical action of that agent. The destructive action of animals, again, is seen in the weakening of rocks on a sea-coast produced by the drilling and boring of *Saxicava*, *Pholas*, &c., and by annelids, echini, and sponges. Rocks so weakened fall more readily before the battering of waves and breakers. Thus, the whole surface of the land, from the summits of mountains down to the sea-coast, is subject to denudation. Little change may be perceptible in a lifetime or even during many centuries, but an examination of the rocks shows that many thousands of feet of solid strata have been gradually removed from the surface of a country. Thus, in many districts where faults occur, no inequality at the surface betrays the presence of dislocations; the whole area has been reduced by denudation to the same level, hundreds or even thousands of feet of strata having been removed from the upcast side of the faults (see DISLOCATION). Some attempts have been made to form a rough estimate of the rate at which the general surface of the land is reduced by denudation. As the sediment of gravel, sand, and mud which a river carries down to the sea represents the actual loss sustained by the surface of the area drained by it and its tributaries, it is obvious that if we could correctly estimate the amount of sediment transported to the sea by the rivers of any given area, we should at the same time ascertain the rate at which that area is denuded. Observation has shown that this denudation proceeds more rapidly in some regions than in others, and, therefore, that the work of no individual river can be taken as a standard by which to estimate the general rate of erosion all the world over. Much depends on physical and climatic conditions, and much on the geological structure of a country and the composition of its prevalent rock-masses. Thus, the Mississippi is said to remove

from the general surface of its basin 1 foot in 8000 years, the Rhone 1 foot in 1528 years, the Po 1 foot in 729 years. To the matter mechanically suspended in the water or swept forward on the beds of rivers we have to add the matter carried in solution, which in many rivers is very considerable. Rivers like the Rhine, the Danube, the Elbe, and the Rhone, contain in every 6000 parts by weight one part of dissolved mineral substance. These rivers, therefore, carry seawards their own weight of dissolved matter in 6000 years. Thus, subaerial denudation progresses more rapidly than we should at first be led to suspect, and those geologists who have made a special study of this question do not hesitate to assert that the action of the subaerial agents of denudation is far more effective than that of the sea, for whereas the action of the latter is confined to a narrow belt of land, that of the former has no such limitation. The whole land surface is exposed to attack, and the loose material carried down to the sea far exceeds in amount the waste of the coast-line by waves and breakers.

**Denver**, the capital of Colorado, is situated on the South Platte River, 922 miles W. of St. Louis. It lies on a level plain, 5169 feet above the sea, beyond which rise the snow-capped peaks and deep blue shoulders of the Rocky Mountains. Denver was founded on a barren waste, dry and treeless, in 1858, and the close of the Civil War saw it a rising frontier town; in 1870 the population was 4759; in 1880, 35,629; in 1900 it had increased to 133,859. In thirty years the mining-camp had been transformed into the 'Queen City of the Plains,' with stately buildings of brick and yellow stone, and wide, shaded streets, provided with electric light and electric tram-cars, and had become the meeting-point of a great network of railways, with four direct routes to the east. In 1910 the population was 213,381; in 1920, 256,491. Among the public institutions and buildings are the state capitol, of Colorado granite and marble, built in 1887-95; the federal building, with U.S. custom-house and post-office, the county court-house, the U.S. mint, the auditorium, the mining exchange, the university (Methodist), with its observatory and other out-buildings, colleges of medicine, law, theology, and music, hospitals, sanatoriums, a zoological garden, the Jesuit college, the Carnegie library, several museums, the episcopal cathedral and many imposing churches, public schools, and theatres. There are many beautiful parks, and an abundant water-supply. The clear invigorating air and dry climate of Denver are famous; the mean annual temperature is 48° F., and the rainfall 17 inches. Denver is the centre of a great agricultural and mining district, and has a large trade in cattle, hides, wool, and tallow, with varied manufactures. It is chiefly to its position as the centre of a great mining region that Denver owes its marvellous progress; the discovery, in 1878, of the fabulous wealth of the Leadville Hills attracted capital and immigration from all parts of the continent. It has a United States assaying mint, and is an important ore market. The neighbourhood produces not only metals—lead, copper, iron, gold, and silver—but also coal, which has created a large smelting industry. It is, in fact, the emporium of the rich gold and silver mining districts of the state, and the chief centre of the coal trade in that region. See also COLORADO.

**Deoband**, a town in the United Provinces of India, 15 miles N. of Muzaffarnagar by rail, with manufactures of fine cloth, and a trade in grain, sugar, and oil. Almost two-thirds the inhabitants are Mohammedans. Pop. 19,000.

**Deodand**. A personal chattel which was the immediate and accidental occasion of the death of a reasonable creature, was, by the law of England, forfeited to the crown, in order that it might be applied to pious uses, or given to God (*Deo dandum*), as the term implies. The law of deodand was abolished by statute in 1846.

**Deodar** (DIODAR), a petty native state in the Palanpur Superintendency, Bombay presidency, with an area of 364 sq. m., and about 30,000 inhabitants. It is a flat, open plain, with sandy soil and a hot climate; there are no rivers, and the numerous ponds are not employed for irrigation. Clarified butter is the only export.

**Deodar**. See CEDAR.

**Deodorisers** are chemical substances employed for the purpose of absorbing or destroying the odouriferous principles evolved especially from decomposing animal and vegetable matter. Thus, freshly burned charcoal is a powerful deodoriser because it absorbs sulphurous acid gas, ammonia, and other odorous gases. They belong to the classes of substances known as Antiseptics (q.v.) and Disinfectants (q.v.).

**D'Eon**. See ÉON.

**Deontology** (Gr. *deon*, 'that which is binding,' and *logos*, 'a discourse'), a term for the science of duty, Ethics (q.v.).

**Deoxidation**, or REDUCTION, is the process of withdrawing the oxygen from a compound, as in the reduction of the native peroxide of iron in the smelting-furnaces to the condition of metallic iron. On the small scale, in experimental inquiries, the process of deoxidation may be carried on before the Blowpipe (q.v.), where the inner or reducing flame is essentially a deoxidising one.

**Department** (Fr. *département*), a term used to denote a territorial division in France. Previous to the Revolution, France was divided into provinces; but in 1790 a decree of the Assembly ordered the abolition of the old provincial divisions (34 in number), and the redistribution of the land into 83 departments. During the year 8 of the Revolution, these were increased to 98; in 1814 the Empire consisted of 130; and the war of 1870-71 reduced it from 89 to 87, including the sadly diminished Haut-Rhin, now Belfort. The war of 1914-18 added Haut-Rhin, Bas-Rhin, and Moselle. The departments, each presided over by a prefect, are again subdivided into *arrondissements*. See FRANCE.

**Dephlogisticated Air**. See PHLOGISTON.

**Depilatories** (Lat. *depilo*, 'I pull out the hair') are chemical agents employed for removing superfluous hair from the skin. They were extensively used by the ancients, but are now restricted in their employment to the face, and to the removal of the hair from the scalp in the treatment of certain diseases. They should only be used under medical advice.

**Deponent**, a term in Latin Grammar applied to verbs having a passive form but an active signification. They are so called because they, as it were, lay down (Lat. *depono*) or dispense with the signification proper to their form. Such verbs had all originally a reflexive meaning, like the middle voice in Greek verbs; thus, *vescor*, 'I eat,' means radically, 'I feed myself.'—*Deponent* is also used for a person who makes a Deposition (q.v.).

**Deposit**, a term much used in Geology, to characterise those rocks which have been formed from matter that has settled from suspension or solution in water. Thus, sandstone and shale are rocks composed of materials which have settled from suspension in water; while stalactites and stalagmites have been precipitated from solution

in water. Deposits are characterised according to the conditions under which they were formed, as marine, lacustrine, fluvial, chemical, and so forth. See SEA, OOZE.

**Deposit**, in English law, is a branch of bailments, defined by Story to be 'a bailment of goods, to be kept by the bailee without reward, and delivered according to the object and purpose of the trust.' See BAILMENT.

**Deposition**, the testimony of a witness set down in writing. Depositions are taken either by a judge or by a commissioner specially appointed by him for that purpose. The questions to which the depositions are answers are usually put by the legal representatives of the parties to the suit, under the control of the court or commissioner, and the answers are taken down by the clerk of court, or by a clerk specially appointed for the purpose. It is a rule in the laws of evidence of all countries that the deposition cannot be read where the witness might be himself produced, because his oral testimony is the best evidence, and secondary evidence is never admissible.

**Depot**, MILITARY, in this country is a place in which recruits are trained and stores kept for Mobilisation (q.v.), and to which reservists come in on the order to mobilise. By the Military Forces Localisation Act of 1872, the United Kingdom was divided into seventy brigade depots. These were afterwards called regimental districts and renumbered. See ARMY.

**Depression**, or DIP. See HORIZON.

**De Profundis** ('out of the depths'), the first words of the Vulgate version of the 129th psalm (A.V. 130th), which is one of the seven 'penitential psalms,' and forms a portion of the liturgy of the Catholic Church, and is sung when the bodies of the dead are committed to the grave. A tender melancholy pervades the psalm, which, however, brightens at the close under the conviction that with God there is 'plenteous redemption.'

**Deptford**, on the south bank of the Thames,  $\frac{1}{2}$  miles below London Bridge, forms one of the metropolitan boroughs and part of another. In 1885 it was constituted a parliamentary borough, returning one member. The parish of Deptford St Nicholas, close on the river-bank, is included in the metropolitan borough of Greenwich. St Paul's parish is the only one in the borough. A royal dockyard, dating from the time of Henry VIII., was repeatedly visited by Queen Elizabeth, who here knighted Captain Francis Drake when he returned from his voyage round the world. It was closed in 1869. Twenty-one acres of its site were bought by the corporation of London, and fitted up as a foreign cattle-market. The Royal Victualling Yard is also here. The Trinity House Corporation has property here; and for sixteen years before his death, the Duke of Wellington as Master went in procession to St Nicholas Church with the Elder Brethren. Since then the ceremony has been disused, and the annual celebration takes place at Trinity Hall, London. Deptford was long famous for horticulture, but the gardens have mostly been built over or used for railway purposes. There is little ship-building now, but there are large and famous marine engineering establishments. In 1888-89 the Electric Lighting Company spent hundreds of thousands of pounds in erecting buildings and laying down plant for supplying London with light. Peter the Great worked here as a shipwright. Lord Howard of Effingham, John Evelyn, author of the *Diary*, Admiral Benbow, Grinling Gibbons, Captain Fenton the associate of Frobisher, and other famous persons lived here; and Christopher Marlowe the dramatist was killed here, and is buried in St

Nicholas churchyard. Deptford is divided from Greenwich by the Ravensbourne, and over the creek there is a bridge where formerly the *depe ford* crossed the river. The lower portions of Deptford were improved in 1888-89, at a cost of about £100,000; the upper portions, New Cross, and Hatcham abound in pleasant residences. The population has grown rapidly, from 27,896 in 1851 to 76,732 in 1881, and 112,500 (metropolitan borough) in 1921.

**Deputy**, one who exercises power which properly belongs to another who has placed him in his stead. The appointment of a deputy does not free the principal from responsibility. See SHERIFF.

**De Quincey**, THOMAS, author of *Confessions of an English Opium-eater*, and of many volumes of essays, criticism, and narrative, was born in Manchester on 15th August 1785. His father, Thomas Quincey, was a linen-merchant with a turn for literature; his mother, whose maiden name was Penson, was a woman of superior position and culture. Of eight children, Thomas was the fifth. An elder brother of imaginative temperament exercised much influence over him; and he records that he was profoundly impressed in childhood by the death of an infant sister. His early years were spent at a mansion built by his father near Manchester, named Greenhay; there his father died of consumption in 1792, leaving his widow and family well provided for. Thomas attended school first at Salford, then at Bath grammar-school, later at Winkfield, Wiltshire, and lastly at Manchester grammar-school. He was an apt scholar; he could converse fluently in Greek at fifteen. In 1802, when he was seventeen years of age, his health failed; and as his guardians refused to remove him from school, he ran away, to wander and study in Wales. He was allowed a guinea a week; but restlessness and want of books and of social intercourse impelled him towards London. There, failing to raise money on his expectations, he underwent singular experiences and privations, related with picturesque power in the *Confessions*. Ultimately he was sent to Worcester College, Oxford, on the inadequate allowance of £100 a year. He disliked and perhaps despised the university system, and left in 1807.

It was in Oxford that De Quincey first resorted to opium to allay pain; the use of the drug for that purpose, and also as a mental stimulant, subsequently became an overmastering and lifelong habit. His mother had now settled near Bath, and at Bristol De Quincey became acquainted with Coleridge's family; and through that connection visited Wordsworth and Southey at the Lakes. In 1808 he revisited Oxford; then went back to London, where he associated with Knight, Lamb, Hazlitt, and other men of letters. In 1809, having provided himself with an ample library, he settled to a literary career at Grasmere. Here, in 1816, he married Margaret Simpson, the daughter of a 'statesman,' one of nature's gentlewomen. They had eight children, three daughters and five sons, two of whom distinguished themselves as soldiers. For about a year (1819) he edited the *Westmoreland Gazette*, a weekly paper published at Kendal, and was an undistinguished contributor to *Blackwood's Magazine*, the *Quarterly Review*, and other periodicals, till his return to London in 1821. His *Confessions* appeared in the *London Magazine*, and at once made him famous. His *nom de guerre*, 'The English Opium-eater,' was used till he came to be known by his proper name, in writing which he assumed the Norman prefix *de*. From London he returned to his wife and family at Grasmere, but finally left Westmorland in 1828, and settled in

Edinburgh; and there, or at Lasswade, near Edinburgh, with only an occasional visit to Glasgow, he lived and worked till his death, on 8th December 1859. *Blackwood's*, *Tait's Magazine*, and latterly *Hogg's Instructor*, were for upwards of twenty years the successive receptacles of his brilliant though often diffuse and discursive papers. The *Logic of Political Economy* (1844), a philosophical contribution to that study, and a romantic story or novel, *Klosterheim* (1839)—his sole and not very successful effort in regular fiction—were issued as books; all his other writings appeared in magazines.

No 'periodical' writer of the 19th century holds a like high and apparently permanent place in English literature with De Quincey. Of several collected editions of his works, the first was one issued in America (1852-55), in 20 vols.; a second, revised by De Quincey, in 14 vols.; another, extended, in 17 vols.; and a fifth, in 1889-91, in 14 vols., ed. by Prof. Masson. De Quincey's writings range over a vast field of literary and semi-philosophical speculation and discussion; and there, as well as in his narrative, historical, critical, and biographical essays, almost faultless refinement of style and marvellous mastery of phrase are conspicuous and charming. In criticism he is original and acute, if not exhaustive or profound; in narrative he marshals facts and incidents in the most picturesque garb and order; in argument he is always subtle, and often vigorous. His playful fancy and wealth of whimsical and humorous allusion enliven almost every topic, and the daring conception and gorgeous colouring of his opium-haunted dreams are not less admirable than the pomp and refinement of the language in which he clothes those weird and wondrous visions. De Quincey is, however, often distressingly diffuse and provokingly addicted to complex involutions of phrase and statement—parenthesis within parenthesis. He is therefore at his best when those tendencies are under control, as in certain passages in the *Confessions*, or in the splendid apostrophes—examples of what he himself calls 'impassioned prose'—that glorify such papers as 'Joan of Arc.'

See Page (A. H. Japp), *Life and Writings of De Quincey* (1877), and *Memorials* (1891); Masson, *De Quincey* ('Men of Letters,' 1881), *Selections* (2 vols. 1888); J. R. Finlay, *Personal Recollections* (1886); Hogg, *De Quincey and his Friends* (1895); Sidney Low, *De Quincey* (1911); W. E. A. Axon, *The Canon of De Quincey's Writings* (Trans. Roy. Soc. Lit., 1912).

**Derain**, ANDRÉ, French figure, landscape, and still-life painter, was born in 1880. He combines the influences of Cézanne and Gauguin with the primitives, the Cubists with the *fauves*, reconciles the new movements with tradition, European and national, and has come to be looked to as their chief by his generation of French painters.

**Derajat**, the fluvial portion of Daman (q.v.), between the Suliman Mountains and the Indus, is, when duly irrigated, singularly fertile. It is now divided between the districts of Dera Ghazi Khan in the Punjab, and Dera Ismail Khan in the North-west Frontier Province.—Dera Ghazi Khan, the capital of one of the districts, is about 2 miles W. of the Indus; pop. 18,500.—Dera Ismail Khan, capital of the other district, is  $4\frac{1}{2}$  miles W. of the Indus; pop. 35,000.

**Derayah**, a town of Arabia, on the caravan route between the Red Sea and the Persian Gulf, 450 miles N.E. of Mecca, was formerly the capital of the Wahabis, and had a population of 60,000 prior to 1819, when it was taken and nearly destroyed by Ibrahim Pasha. The capital was removed to Riâd, 6 miles E.N.E.; and at present the place consists of five walled villages, built among the ruins, with about 1500 inhabitants.

**Derbend**, or DERBENT ('gateway'), a port and capital of the Russian republic of Daghestan, on the west shore of the Caspian, 140 miles N.W. of Baku. It is charmingly situated among vineyards and orchards and fields of maize and madder, on the declivity of a branch of the Caucasus, which here approaches very close to the water's edge. Derbend is surrounded by ancient walls. The upper city forms the citadel, and contains the splendid palace of the ancient khans, later the residence of the Russian governor. The harbour is inaccessible to all but small vessels; but a considerable trade is done at the four large markets held here yearly. Silk and cotton fabrics, earthenware, and weapons are manufactured, and saffron is cultivated. Pop. 40,000. Derbend was for long considered the key of Persia on the north-west side. It was captured by the Arabs in 728, by the Mongols in 1220, and frequently changed hands before it was formally incorporated with Russian Caucasia in 1813.

**Derby**, a parliamentary, municipal, and county borough and manufacturing town, the capital of Derbyshire, stands on the Derwent, 92 miles S.E. of Liverpool and 114 NNW. of London. The Roman station of *Derwentio* was at Little Chester, a northern suburb of Derby. It was one of the Danish Five Boroughs. Many early charters were granted to the bailiffs and burgesses of Derby; but it was not till 1638 that it was placed under the jurisdiction of a mayor. It has sent two members to parliament since 1295. The tower of All Saints (1509-27) is a grand example of Perpendicular architecture, 175 feet high, exclusive of the pinnacles. All Saints was selected for the cathedral of the new diocese of Derby, which it was decided in 1923 to detach from Southwell. The Roman Catholic Church of St Mary (1835) is a good specimen of Pugin's work. The ancient chapel of St Mary-on-the-Bridge still exists. The municipal buildings are unattractive. There is a good free library and well-filled local museum, occupying handsome and suitable buildings, the gift of Mr M. T. Bass, for thirty-five years M.P. for Derby. The grammar-school is a modern erection, but was founded in 1162. The choicely planted arboretum (23 acres), near the central railway station, was mainly the gift (1840) of Mr Joseph Strutt. Derby is a great railway centre, with vast offices, storehouses, workshops, and engineering establishments, and direct, speedy, and frequent access to all parts of the kingdom. Its manufactures are silk, cotton, elastic web, lace, hosiery, iron, lead, shot, spar, porcelain, and paper. Silk, one of its staple manufactures, was begun here first in England by John Lombe in 1719. The mill that he then erected still stands on an island in the Derwent. Porcelain was manufactured here by the Duesbury family from 1756 till 1814; and the Derby Crown Porcelain Company revived this beautiful industry with much success. 'Wright of Derby,' the painter, and Herbert Spencer, were natives; and Derby is identified with the 'Stoniton' of George Eliot's *Adam Bede*. Pop. (1841) 32,741; (1881) 81,168; (1891) 94,140; (1901) 105,785; (1911, with extended bounds) 123,410; (1921) 129,836.

**Derby**, EARL OF, a title conferred in 1485 on Thomas, second Lord Stanley, two months after Bosworth Field, where he and his family had greatly contributed to Richmond's victory. The Stanleys were descended from William de Stanley, who became forester of Wirral by marriage with an heiress in the 13th century. In 1405 Sir John Stanley, who had married the heiress of Lathom, got a grant of the Isle of Man (q.v.), which he and his descendants ruled till 1736. James, seventh Earl of Derby

(1606–51), fought on the royalist side throughout the Great Rebellion, and, taken prisoner after Worcester, was beheaded at Bolton; his countess, Charlotte de la Trémoille, is famous for her heroic defence of Lathom House (1644) and of the Isle of Man (1651).

EDWARD GEOFFREY SMITH STANLEY, fourteenth EARL OF DERBY, was born in 1799, at Knowsley Hall, Lancashire. He was educated at Eton and Christ Church, Oxford, where, in 1819, he gained the Latin Verse prize (subject, *Syracuse*). He was elected member of parliament for Stockbridge in 1820; in 1825 he married the second daughter of the first Lord Skelmersdale; and in 1826 he represented Preston, but lost his seat in 1830, on becoming Chief-secretary for Ireland under the administration of Earl Grey. A seat was soon found for him at Windsor. He took a distinguished part in the debates in favour of the Reform Bill, and signalled his Irish administration by two bold measures—one for National Education in Ireland, and another relative to the Irish Church Temporalities, which resulted in ten Irish bishoprics being abolished. The grievance of church-rates and first-fruits was also removed, and a graduated tax upon benefices and bishoprics substituted. In 1833 he became Secretary of State for the Colonies, and in the same year carried the bill for emancipating slaves in the West Indies. In 1834, being alarmed by the success of Mr Ward's motion for appropriating the surplus of the Irish Church temporalities to secular purposes, Mr Stanley seceded from the Whigs, carrying with him Sir James Graham, the Duke of Richmond, and the Earl of Ripon. In November, upon the dismissal of the Melbourne ministry, he declined to join the Peel administration, and the Stanleyites maintained an independent position for several years. He accepted, however, the colonial seals in 1841, and held them for four years. In 1844 he resigned his seat for North Lancashire, for which he had sat since 1832, and was called to the Upper House in his father's barony of Stanley of Bickerstaffe, having for ten years before borne the courtesy title of Lord Stanley, through his father's succession to the earldom of Derby. In December 1845, when Sir Robert Peel determined to repeal the corn laws, he retired from the cabinet. In 1846 he put himself at the head of the Protectionists, who, headed in the Commons by Lord George Bentinck and Mr Disraeli, waged a stout but ineffectual opposition to the free-trade measures of Sir Robert Peel. He was now regarded as the leader of the great Conservative party.

In 1851, on the death of his father, he succeeded to the earldom. In February 1852, on the resignation of Lord John Russell, he was intrusted with the formation of an administration, which was, however, displaced in December following by a hostile vote of the House of Commons condemnatory of Disraeli's budget. On Wellington's death (1852) he was elected Chancellor of the University of Oxford. In February 1858, when the Palmerston government resigned on the rejection of the Conspiracy Bill, he again became First Lord of the Treasury. At the meeting of parliament in the following year, his government brought forward a measure of parliamentary reform. A hostile amendment having been moved by Lord John Russell, and carried, he dissolved parliament, and appealed to the country. When the new House of Commons reassembled in June 1859, a vote of want of confidence was carried against his government, and he resigned. He returned to power in 1866, and, in conjunction with Disraeli, passed the Reform measure of 1867. In 1868 he resigned the premiership in favour of Disraeli. His last speech in

parliament was made (1869) in opposition to the disestablishment of the Irish Church. He died at Knowsley Hall, 23d October 1869. Lord Derby was styled by Lord Lytton 'the Rupert of debate,' and stood in the very first rank of parliamentary speakers. His power of invective was almost unequalled, and his vehement contentions with O'Connell on the Repeal of the Union did much to diminish the influence of the Irish agitator. Besides being an accomplished scholar, he was a keen sportsman and a popular landlord. But he cared little for office, and more than once injured the fortunes of his party by declining to form a ministry, notably on the fall of Lord Aberdeen in 1855. Lord Derby (who was offered the crown of Greece in 1862–63) published in 1864 a blank-verse translation of Homer's *Iliad*. See *Lives* by Keibel (1890), and Saintsbury (1892).

EDWARD HENRY SMITH STANLEY, fifteenth EARL OF DERBY, K.G., D.C.L., LL.D., F.R.S., eldest son of the above, was born in 1826, and educated at Rugby and Trinity College, Cambridge, where he took firsts in classics and mathematics. In 1848 he was elected member of parliament for King's Lynn, and in 1852 was appointed Under-secretary for Foreign Affairs in his father's first ministry. After declining to join Lord Palmerston's ministry in 1855, Lord Stanley became Secretary for India in his father's second administration (1858–59), and carried the important measure which transferred the government of India from the Company to the crown. He was Foreign Secretary in the third Derby and first Disraeli ministries (1866–68). He succeeded his father in the earldom in 1869. In 1874 he again became Foreign Secretary under Disraeli; but resigned in March 1878, when the majority of the cabinet determined to support the tottering cause of Turkey by calling out the reserves and occupying Cyprus. After holding aloof from politics for several months, he definitely joined the Liberal party in 1880, and was Secretary for the Colonies from 1882 to 1885. In 1886 he declined to follow Mr Gladstone on the question of Home Rule for Ireland, allying himself with the Unionist party. Lord Derby, who was Lord Rector of Glasgow University in 1868–71, and of Edinburgh University in 1875–80, died at Knowsley, 21st April 1893. His *Speeches and Addresses*, privately printed in 1893, were published with a *Memoir* by Lecky in 1894. His speeches on economical subjects were singularly suggestive.

His brother FREDERICK ARTHUR STANLEY, sixteenth Earl (1841–1908), Governor-general of Canada (1888–93), was succeeded by his son EDWARD GEORGE VILLIERS STANLEY, K.G., G.C.B., who, born 4th April 1865, had as Lord Stanley sat as a Conservative for West Houghton (1892–1906), and had been a Lord of the Treasury (1895–1900), Chief Press Censor in South Africa, and Private Secretary to Lord Roberts, Financier, Secretary to the War Office (1900–3), and Postmaster-general (1903–5). As Director-general of Recruiting, he managed the 'Derby Scheme.' He was Secretary for War under Mr Lloyd George, Mr Bonar Law, and Mr Baldwin, and ambassador to France, 1918–20.

**Derby Day** is the second day, the Wednesday, of the Summer Meeting which takes place at Epsom in Surrey, usually towards the end of May, but sometimes early in June. Upon this day, the most important on the list, and that on which the best horses run, the famous Derby stakes, instituted by the Earl of Derby in 1780, are contended for. When the first Derby was run for, there were only 36 subscribers at 50 guineas each (with 25 guineas forfeit in case of non-starters); and for the first half-century the subscribers never numbered 90; but after 1830 there was a rapid increase, and in

1879 (which completed the century) there were 278 subscribers, and the value of the stakes exceeded £7000. Subsequently the numbers diminished till, in 1888, there were only 158 subscribers, and no more than nine horses ran, while the value of the stakes was £3675. In order to increase the competitors in future, the conditions of the race were then altered. Since 1825 (when the subscription was changed from guineas to sovereigns) the fee has been £50 each, with £25 forfeit in case of non-starters; and the value of the stakes has varied with the number of subscribers. Under the new regulations (coming into operation with the Derby of 1890) there was a fixed prize of not less than £5000 for the winner, and smaller prizes for second and third; and any surplus from the entrance fees went to the winner. The full subscription is still £50, but there are two forfeits—viz. £10 only if the declaration of forfeit is made about eighteen months prior to the race, or £25 if made about six months before the race. The entries are made about two years before the race, when the animals are yearlings. The alteration of conditions proved attractive to racehorse owners, as the entries for the Derby of 1890 rose to 238. In 1903 the Derby was made a stake of £6500, with £400 and £200 for the second and third, or more according to subscriptions. In 1915–18 the race was run at Newmarket, owing to war conditions. The Derby Day is a great English holiday. To be present at Epsom on that occasion London empties itself, and proceeds to the Downs by modes of locomotion the most heterogeneous. For hours a continuous stream of vehicles moves tumultuously along the road to Epsom. Parliament used to adjourn; people of every condition come in countless numbers from all districts, and huge trains arrive every few minutes at the station, bringing their thousands, until the entire Downs are covered with a vast moving mass. At the Derby in 1861, the course, which is a mile and a half in length, was gone over in 2 minutes 43 seconds—the swiftest running, by 2 seconds, ever known on that course up to that time. In 1864 the race was run in the same time, although the horses carried 3 lb. more weight than before. In 1887 and again in 1888 the race was run in 2 minutes 43 seconds, although 4 lb. more had been added to the weight. When the Derby was first instituted the weights were 8 stone for colts and 7 stone 11 lb. for fillies; but they have been raised several times, until now colts have to carry 9 st. and fillies 8 st. 9 lb. It was run in 1910 in 2 minutes 35½ seconds; in 1920, in 2 minutes 34½ seconds.

**Derbyshire**, an inland county of the north midland district of England, lies between Yorkshire on the north and Leicestershire on the south, and is flanked on the east by Notts, and on the west by Staffordshire and Cheshire. The shire is of an irregular triangle shape, with the apex to the south; its greatest breadth is 34 miles, and its length 56; its area extends over 1016 sq. m., or 650,369 acres. Pop. (1801) 161,567; (1841) 272,202; (1881) 461,914; (1921) 714,539. The surface of the county is much diversified, the south being for the most part flat, the east of a varied and undulating character, but the north exceptionally hilly and rugged. The high land of the north, usually known as the Peak, is the southern termination of the Pennine Chain, and forms the watershed between the Trent and the Mersey. Several summits exceed 2000 feet in height. North Derbyshire is justly celebrated for its picturesque scenery, which chiefly centres in the valleys made through the limestone by the rivers Derwent and Wye. Matlock and Buxton, where there are warm mineral springs, are the two chief places of resort. Other chief towns are Derby, Chesterfield, Glossop, Ilkeston, Ashbourne, Bakewell, Belper, and Wirksworth.

The county now returns eight members to parliament, besides two for the borough of Derby.

In addition to important coal-mining, chiefly in the eastern division, Derbyshire is singularly wealthy for its area in a diversity of minerals and metals; iron, lead, zinc, manganese, copper, gypsum, pipeclay and chert for potteries, marble, fluor-spar, and alabaster being all worked within its boundaries. The chief manufactures are cotton, silk, elastic web, worsted, flax, lace, metallic goods, porcelain and pottery, and fluor-spar ornaments. Though more a manufacturing and mining than an agricultural country, Derbyshire is not undistinguished for its pastoral and corn-growing properties. The chief crops are wheat, barley, and oats. Of the total area, three-fourths is under crops of all kinds, bare fallow, and grass. There is much permanent pasture and large sheep-walks in the Peak district. Several dairies of repute are in the south of the county, and their produce is chiefly taken by cheese-factories on the American principle. There are ruins of abbeys at Dale and Beauchief, and peculiarly fine churches at Melbourne, Ashbourne, and Tideswell. The Saxon crypt and chancel of Repton, and the churchyard crosses of Eyam, Bakewell, Hope, &c., are the oldest ecclesiastical remains. Of feudal and domestic buildings may be named the castles of Castleton, Bolsover, and Duffield, the manor-house of South Winfield (ruin), Haddon Hall, and Hardwick Hall. Chatsworth (q.v.), the seat of the Duke of Devonshire, is unrivalled. The caves and numerous tumuli or 'lows' have yielded many evidences of prehistoric and Celtic man; whilst the traces of Roman occupation are numerous. Arbelow, near Youghreave, is the most important 'stone circle' in England next to Stonehenge. Though a turbulent county in English history, and ever taking part in all civil tumults, Derbyshire has not furnished the site of any remarkable battle nor played any special part in national affairs; its chief historic association is the retreat in 1745 of Prince Charles Edward, Derby being the turning-point in his bold but rash enterprise. The county claims as natives, Flamsteed the astronomer, Richardson the novelist, Chantrey the sculptor, and Brindley the engineer. Lombe first established an English silk-mill at Derby in 1719, and Strutt and Arkwright first made English calicoes at Gromford in this county in 1773.

See Pendleton's *History of Derbyshire* (1886); the works of Dr Cox, *Guide to Derbyshire, Churches of Derbyshire* (4 vols. 1876–79), and *Three Centuries of Derbyshire Annals* (1891); *The Old Halls, Manors, and Families of Derbyshire* (1891 *et seq.*); and the 'Victoria History' (1906 *et seq.*).

**Derbyshire Neck** is Goitre (q.v.).

**Derbyshire Spar** is Fluor-Spar (q.v.).

**Dereham**, EAST, a pleasant, thriving market-town of Norfolk, 17 miles WNW. of Norwich. Here, in 650, St Withberga founded a nunnery. It was burned by the Danes, but afterwards re-founded; and its cruciform church remains, with a detached belfry (the 'New Clocker'), a font of 1468, a good south porch, St Withberga's well, and the grave of the poet Cowper. Bonner was a vicar, and Wollaston and Borrow natives. Dereham has manufactures of agricultural implements. Pop. of urban district (1921) 5659.

**Derelict**, anything forsaken or left unoccupied, specially a wrecked ship; but it is necessary that the master and crew shall have abandoned the ship, without hope of recovery. When abandonment has occurred, the first-corners are entitled to take temporary possession of the ship. See SALVAGE, WRECKS. Wooden ships are more apt to become derelict than iron ones, and timber-laden ships are

specially liable to become dangerous in this way. The North Atlantic as the great ocean highway is most embarrassed by derelicts. In five years as many as 950 derelict ships have been reported at Washington between 52° W. lat. and the American coast. The British Board of Trade, the Washington Hydrographic Office, and the Deutsche Seewarte receive reports of derelicts noticed at sea, and issue information about them to shipmasters. Some ships have been known to float derelict for two or three years, and in that time to have drifted to and fro for 3000, 8000, or even 10,000 miles. See an article in *Chambers's Journal* for 1911.

**Derg**, ЛОУН, the largest lake expansion of the river Shannon, separating Tipperary from Galway and Clare, is 24 miles long, with an average width of 2 miles; greatest depth, 80 feet. Its surface is about 100 feet above the sea.—Another Lough Derg, in the south of Donegal county, is 3 miles by 2½, has many small isles and rocks, and wild dreary shores. Saint's Isle contains the remains of a priory. Station Island, the reputed entrance to St Patrick's Purgatory, was long the most celebrated place of pilgrimage in Ireland.

**Derketo**, Greek form of ATARGATIS, the name of the Syrian fertility goddess, female counterpart of Baal. She was worshipped, especially at Hierapolis, with phallic emblems, orgiastic rites, and self-mutilation. See Lucian, *De Dea Syria*.

**Dermaptera**. See FLYING ANIMALS, INSECTIVORA.

**Dermatogen**. See EMBRYO.

**Dermatology**. See SKIN.

**Dermatophytes** (Gr. *derma*, 'the skin,' and *phyton*, 'a growth' or 'plant'), vegetable growths, chiefly of the lowest fungi, moulds, &c., inhabiting the cuticle or epidermis, and giving rise to some forms of skin-disease, as Favus (q.v.), Pityriasis (q.v.), Ringworm (q.v.), &c.

**Dermestes**, a genus of beetles, one of which is *D. lardarius*, the Bacon Beetle. It lives in the open air on dead animals, but within doors attacks bacon, cheese, dried meats, furs, cabinet collections, &c. The brown larvæ are equally voracious.

**Derna**, an exposed port on the coast of the province of Barca or Bengazi, half-way between Bengazi and Sollum, on a fertile and well-watered coast strip, with a good deal of trade; pop. 11,000. It was occupied by the United States in 1805, and taken possession of by the Italians in 1911.

**Derrick**, a kind of Crane (q.v.), so named after Derick, an English 17th-century hangman.

**Derry**. See LONDONDERRY.

**Dervish**, signifying 'poor,' is a Persian word (derived from a root connected with 'door,' indicating the door-to-door mendicancy of the dervish) of which the Arabic equivalent is *Fakir* (q.v.). It designates, in Mohammedan countries, a class of devotees who correspond in their various aspects with the monks, the mendicant friars, and the freemasons of medieval Europe. Some are wanderers, depending upon alms, and often demanding charity with insolence; others are settled for the most part in convents, called Tekyas or Khânkâs, where they observe special rites, or devote themselves to solitary meditation and penance; others, again, are more like freemasons—ordinary tradesmen and labourers for most of the year, and exercising their special ceremonies only on stated occasions; whilst some, again, form a class of religious entertainers, who are hired out to chant their monotonous dirge or *Zikr* at public and private festivals. They belong to an infinity of orders or brotherhoods, among which the best known are the Kâdiris (commonly known in Europe as the 'howling dervishes,'

on account of their peculiar chant), founded 1165 A.D.; the Rifâ'is (1182), formerly famous for their feats of eating glass and live coals and swallowing swords, and also for the ceremony, recently abolished, of the *Döşeh*, where the sheikh of one of their sub-orders (the Sa'dis) rode over the prostrate bodies of the faithful in the streets of Cairo; the Mevlevîs (1273), or 'dancing'—i.e. whirling—dervishes; the Nakhshibendis (1319); Bektâshis (1357), whose founder blessed and named the famous corps of Janizaries (q.v.); the Jemâlis (1750); and the Kalerideris, the 'calenders' of the *Arabian Nights*, who are under a vow of perpetual tramping: the names are taken from those of their founders.

Mevlevîs, or Dancing Dervishes.

The various orders have distinctive dresses, and the sheikh or pir who commands them is also distinguished from his followers by his robes. The conical cap of the Mevlevî is well known. The rites of the different orders when they meet together vary, but consist chiefly in prayers, religious dances, monotonous recitations of the name of God and of certain pious formulas. Frequently the devotees work themselves into a state of spiritual frenzy which is accompanied by extravagant, and, to the vulgar, miraculous, feats of strength and endurance, and not unfrequently terminates in an epileptic seizure. The dervishes and their performances are held in the deepest veneration by the people, and sultans have often held them in high respect, and bestowed large endowments upon their tekayas.

It is difficult to say when these religious orders took their rise. From the earliest times, pious persons in the East have held it to be meritorious to renounce earthly joys, to free themselves from the trammels of domestic and social life, and to devote their thoughts in poverty and retirement to the contemplation of God. In this sense, poverty is recommended by Mohammed in the Koran, though monachism is distinctly repudiated. Tradition refers the origin of these orders to the earliest times of Islam, making the khalifs Abû-bekr and 'Alî found such brotherhoods; but most of them are of much later date.

**Derwent**, the principal river of Tasmania, issues from Lake St Clair, in the centre of the island; flows tortuously to the south-east; and enters Storm Bay at Hobart by an estuary 4 miles wide, after a course of about 130 miles. Up to Hobart the Derwent is navigable for ships of any burden.

**Derwentwater**, a sheet of water, stretching south from Keswick, the most beautiful of the Cumberland lakes. Lying 244 feet above sea-level, and engirt by steep wooded crags and hills, it is 3 miles long by 1½ broad, and 72 feet deep at the deepest. Near its foot rises Castle Head (529 feet),

commanding an exquisite view; whilst at its head are the celebrated Lodore Falls and Borrowdale (q.v.). This lake is an enlargement of the Derwent River, which traverses it in its course towards the Irish Sea at Workington. It has several wooded isles, sometimes a floating island. Perch are the most plentiful fish. See FLOATING ISLANDS.

**Derwentwater**, JAMES RADCLYFFE, EARL OF, one of the leaders in the rebellion of 1715, was born in 1689, and educated in France. He succeeded as third earl in 1705, on the death of his father, who had married Lady Mary Tudor, Charles II.'s daughter by Moll Davis. On the eve of the insurrection, at the close of 1714, warrants were issued on suspicion against several gentlemen in the north of England, and one, among others, against the young Catholic earl; but having been previously warned, he fled from Dilston, his seat in Northumberland, and found refuge in the cottage of one of his dependents. He soon afterwards placed himself at the head of a few retainers, under the impression that the whole body of the Jacobites either had risen, or were about to rise. From this point the history of the Earl of Derwentwater becomes the history of the Rebellion of 1715 (see JACOBITES), which ended in the disastrous encounter at Preston, where Derwentwater bore himself with the utmost heroism, but, with most of the rebel leaders, was taken prisoner, and conveyed to the Tower of London. Impeached of high treason at the opening of parliament, he was brought to trial in Westminster Hall, when he pleaded guilty, and threw himself upon the mercy of the king. His appeal was unavailing, and he was condemned to die. Every possible effort was made by his kinsfolk and friends to obtain a pardon, but their exertions were fruitless, and he was beheaded on Tower Hill, 24th February 1716. His youth and amiability, his rank and valour, combined to excite great sympathy for the hapless earl. He is the hero of a touching ballad of the day, and of *Dorothy Forster*, Sir Walter Besant's charming romance.

**Derzhavin**, GABRIEL ROMANOWICZ, the great poet of the age of Catharine, was born at Kazan, 3d July 1743 (o.s.), studied at the gymnasium of his native city, and in 1762 entered the army as a private soldier. His talents and superior education soon procured him promotion. In 1791 he became Secretary of State; in 1800, Imperial Treasurer; and in 1802, Minister of Justice. He died 9th July 1816. His poetry shows a vigorous imagination and strong power of expression, though his imagery at times verges on bombast. His lyric pieces are full of fire. His noblest, as well as his most popular ode, is his *Address to the Deity*, which has been translated into the western languages. His collected works have often been republished since 1798.

**Desaguadero** ('channel' or 'outlet'), the name of various waters in South America, of which the principal is the Rio Desaguadero in Bolivia (q.v.).

**Desaix de Veygoux**, LOUIS CHARLES ANTOINE, a famous French general, was born of a good old family at St Hilaire-d'Ayat, in Auvergne, August 17, 1768. Entering the army at fifteen, in 1796 he covered himself with glory by his heroic conduct in Moreau's famous retreat through the Black Forest. Behind the ruinous fortress of Kehl, Desaix resisted the Austrian army for more than two months, only capitulating in January 1797, when his ammunition was spent. His greatest achievement was the conquest of Upper Egypt, which he accomplished in 1799, after an eight months' campaign. His own soldiers used to compare him to Bayard, while the inhabitants named him 'the Just Sultan.' Desaix returned from Egypt just in time to take part in

the battle of Marengo, in which he was killed by a musket-bullet, 14th June 1800.

**De Sanctis**, FRANCESCO (1817-83), Italian critic, historian, and minister of education, was born at Morra. A teacher in Naples, he took office under the revolutionary government in 1848, and was imprisoned for three years on the restoration of the Bourbons. On his release he fled to Malta, and lectured in Turin and Zurich. In 1860 he was minister of education for Naples, and in 1861-62, 1878, and 1879-80 for Italy. In 1871 he was appointed to a chair in Naples university. As a critic he was the forerunner of Croce (q.v.). His works include *Storia della letteratura italiana*, *Saggi critici*, *Nuovi saggi critici*, *La letteratura italiana nel Secolo XIX.*, and studies of Petrarca and Leopardi.

**Desaugiers**, MARC, a once popular poet, whom some critics have set above Béranger, was born in 1772. After travelling abroad, he settled in Paris, where he became a writer of songs and vaudevilles. His subjects are generally love and wine; his verse is sweet and flowing. 'He is,' says Mr Saintsbury, 'the best light song-writer of France, with the single exception of Béranger.' He died in 1827.

**Desbarres**, JOSEPH FREDERICK WALLET, military engineer, was born 1722 in England, of Huguenot parentage, and in 1756 sailed as lieutenant in the 60th foot for America, where he raised, and for a time commanded, a corps of field artillery. In 1757 he gained over the Indians who had captured Fort Schenectady; and at the siege of Quebec he was aide-de-camp to Wolfe, who was mortally wounded while Desbarres was making a report. He conducted the subsequent engineering operations during the conquest of Canada, and was quartermaster-general in the expedition that retook Newfoundland (1762). He made a survey of the coast of Nova Scotia in 1763-73, and afterwards prepared charts of the North American coast for Lord Howe. He was lieutenant-governor of Cape Breton (1784-1804), and of Prince Edward Island (1805-13), having attained the rank of colonel only in 1798. He died at Halifax, Nova Scotia, 24th October 1824, at the age of one hundred and two. His principal publication was the *Atlantic Neptune* (4 vols. 1777), a splendid collection of charts.

**Des'cant**, in medieval music, was the art of adding a part or parts to a melody or subject. The latter being almost invariably given to the tenor, descant came to signify generally the upper part, or *air*, of a piece. See COUNTERPOINT.

**Descartes**, RENÉ (Latinised into RENATUS CARTESIUS), generally regarded as the father of modern philosophy, was born March 31, 1596, at the village of La Haye, near Tours. He was sent at the age of eight to the Jesuit College at La Flèche, where he soon became distinguished for his keenness of intellect, and made great and rapid progress in languages, mathematics, and astronomy. It was not long, however, before he became dissatisfied with the doctrines and method of scholasticism, and felt it impossible to acquiesce in what had hitherto been regarded as *knowledge*. The first thing that he did after leaving college, as we are informed in his treatise on Method, was to abandon books, and endeavour to efface from his mind all that he had hitherto been taught, that it might be free to receive the impressions of truth, whencesoever they should come. In pursuance of his plan he resolved to travel, and served successively in Holland, Bohemia, and Hungary, in the armies of the Prince of Nassau and the Duke of Bavaria. It was while he was in winter-quarters at Neuburg on the Danube (St Martin's Eve, 1619, as he himself informs us) that there first dawned

upon him the principles of the new method which he afterwards applied in philosophy and for the reorganisation of knowledge generally. So in 1621 he left the army, but continued to travel as a private gentleman, with occasional residences in Paris, till 1629. In that year he retired to Holland, where he lived in great seclusion for twenty years, devoted to the elaboration of his discoveries and the publication of his chief works. In time his doctrines attracted many disciples in the land of his adoption, but involved him at the same time in bitter controversy with the Dutch theologians. These unpleasant encounters had probably their share in inducing him to accept an invitation to go to Sweden, addressed to him by Queen Christina, who desired his learned intercourse and instruction. He left Holland in September 1648, but his constitution was not able to stand the rigour of the northern winter and the exposure involved in waiting upon the queen at five every morning for an hour's philosophical instruction. He died at Stockholm of inflammation of the lungs on 11th February 1650. Sixteen years later his body was brought to Paris, and buried in the church of Ste. Geneviève-du-Mont. In 1819 his remains were again transferred to St Germain-des-Prés, where they now rest.

The grand object towards which Descartes directed his endeavours was the attainment of philosophical certainty. The way whereby he sought to attain this end is explained in the Discourse on Method (*Discours de la Méthode*, published in 1637). This small but extremely interesting and important treatise contains a history of the inner life of the author, tracing the progress of his mental development from its commencement in early years, to the point where it resulted in his resolution to hold nothing for true until he had ascertained the grounds of certitude. The author also, in the same treatise, lays down the methodical rules by which he resolved to guide his inquiries, and by the observance of which he hoped to arrive at *absolute certainty*, if indeed it were at all attainable. The results of his inquiries are indicated in the Discourse, but are exhibited more particularly in his *Méditations de Prima Philosophiæ* (Amst. 1641), and the *Principia Philosophiæ* (Amst. 1644). Doubt, according to Descartes, is the philosophic starting-point, the solvent which we must bring to bear upon all our inherited beliefs and opinions. This doubt is to be distinguished from scepticism, which is a permanent state of mind and involves despair of truth. It is to be regarded simply as an instrument of philosophical inquiry, and as such has received the name of Cartesian doubt. Applying this test relentlessly to all that had hitherto borne the name of knowledge, Descartes found one, and only one proposition that seemed to him to stand firm, and of which the truth could not possibly be doubted: that proposition was that he existed, which he inferred from the fact of his possessing consciousness. He could not doubt that he felt and thought, and therefore he could not doubt that *he*, the feeler, the thinker, existed. This relation between consciousness and existence he expressed by the memorable words: *Cogito, ergo sum*. On inquiring further into the ground of his certitude in the case of this proposition, Descartes was able to assign no further reason than that he saw very clearly that in order to think, it is necessary to exist. He formulated, therefore, the following criterion of certainty—that *whatever is clearly and distinctly thought, must be true*. Amongst these clear and distinct thoughts he soon recognised the idea of God as the absolutely Perfect Being. This idea, he reasoned, could not be formed in our minds by ourselves, for the imperfect can never originate the perfect; it must be *connate*—i.e. part of the original

structure of our understanding, and implanted there by the Perfect Being himself. Hence, from the existence of the idea of perfection, Descartes inferred the existence of God as the originator of it; he inferred it also from the mere *nature of the idea*, because the idea of perfection involves existence. The latter is known as the ontological argument, which Descartes thus reintroduced into modern philosophy. But if God exist, then we have a guarantee, according to Descartes, of the previously determined ground of certitude, for God the Perfect Being cannot deceive, and therefore whatever our consciousness clearly testifies may be implicitly believed.

The most general fundamental principle of the philosophical system of Descartes is the essential difference or dualism of spirit and matter—the thinking and the extended substances—a difference so great, according to Descartes, that they can exert no influence upon each other. Mind or spirit is pure consciousness, and matter is mere extension; these attributes are mutually exclusive, and hence these two 'created substances' can be united (as we find them, for example, in the human being) only through the intervention of the infinite substance or God. This doctrine led directly to the system called *occasionalism*, the principle of which was that body and mind do not really affect each other, God being always the true cause of the apparent influence of one on the other. A volition on our part is merely the *occasion* of God's producing a corresponding bodily motion, and similarly the material processes in the nerves and brain are only the occasion, not the cause, of the ensuing mental result. This doctrine was further developed by Leibniz in connection with his doctrine of pre-established harmony (see LEIBNIZ). The human body being thus a mere machine accidentally united to a rational soul, it was an immediate consequence of the Cartesian doctrine that animals (in which the rational soul is absent) are literally automata; their cries no more imply feeling than the creaking of a machine. This ruthless product of logical consistency unfortunately led to cruelty in practice.

Descartes did not confine his attention to mental philosophy. His philosophy is in fact only the introduction to an elaborate system of physics. In this department it is noteworthy that he completely discarded final causes and proposed to himself the explanation of all physical phenomena from matter and motion. His celebrated theory of vortices, devised to explain the motions of the heavenly bodies, held the field till it was superseded, after a stubborn resistance, by the Newtonian theory of gravitation. It was in mathematics, however, that Descartes achieved the greatest and most lasting results. It was Descartes who first recognised the true meaning of the negative roots of equations; and we owe him the theorem, which is called by his name, that an equation may have as many positive roots as there are changes of sign in passing from term to term, and as many negative roots as there are continuations of sign, and not more of either kind. He gave a new and ingenious solution of equations of the fourth degree; and first introduced *exponents*, and thereby laid the foundation for calculating with *powers*. He showed, moreover, how to draw *tangents* and *normals* at every point of a geometrical curve, with the exception of mechanical or transcendental curves; and what perhaps was his highest merit, he showed how to express the nature and the properties of every curve, by an equation between two variable co-ordinates; thus, in fact, originating *Analytical Geometry*, which has led to the brightest discoveries.

Editions of Descartes' collected works were published in Latin in 1697 and 1713, in French by Cousin in 1824–26, and by Adam and Tannery (Centenary edition,

1897-1906). His philosophical works were translated by Miss Haldane and G. T. Ross (1911). His correspondence with Constantyn Huygens, 1635-47, is edited by Leon Roth (1926). See books by Millet (1887-71), Fouillée (1893), De Swarte (1904), Hoffmann (1922), Kuno Fischer (trans. 1887); and English works by Cunningham (1877); Lowndes (1878), Mahaffy (1880), Martineau (1885), and Miss Haldane (1906).

**Descendants.** See HEIR, CONSANGUINITY, PEDIGREE, SUCCESSION.

**Descent of Man.** See MAN, DARWINIAN THEORY.

**Deschamps, EUSTACHE**, a French poet, who was born at Vertus, in Champagne, in 1328. He was educated at Orléans University, and was in the course of his life a soldier, a magistrate, a court favourite, and a traveller in Italy and Hungary. He held several important posts in his native province, but his possessions were ravaged by the English, and he seems to have been a poor man when he died in 1415. He was both a popular and voluminous writer. He composed 1175 *ballades*, a multitude of *rondeaux*, *virelais*, and other lyrics, besides a long poem of 13,000 lines, entitled the *Miroir de Mariage*—his works in all amounting to more than 100,000 lines. Deschamps was an ardent patriot, in whose verse hatred of the English and of the native oppressors of the French poor finds repeated and bitter expression. His thought is, as a rule, grave and dignified, but his style is somewhat wanting in elegance and ease. Occasionally, however, as in his lament for Du Guesclin, his verse is both graceful and touching; and in at least one piece, an apologue exposing the exactions of the rich, he gives proof of a grim and trenchant satiric faculty. See the Marquis de Queux de Saint-Hilaire's edition (1878-95), Sarrafin's monograph (1878), Besant's *Early French Poets* (1868).

**Deschanel, PAUL EUGÈNE LOUIS** (1856-1922), born at Brussels, wrote on political subjects, Mme. de Sévigné, Lamartine, and Gambetta. He was president of the French Chamber and (January to September 1920) of the republic. The strain of office brought a nervous break-down. He fell from a railway train in May, and had at last to resign.

**Deseret.** See UTAH.

**Desert** is the geographical name applied to a barren and uninhabitable portion of the earth's surface. Four classes of desert may be distinguished.

(1) *Ice-wastes* occupy the central plateau of Greenland, the islands of the Arctic Sea, and probably the entire Antarctic continent. The ground is covered to an unknown depth by a vast ice-cap, hummocky on the surface, and moving outwards to the coasts in a continual procession of glaciers.

(2) *Tundras* are flat plains, little elevated above sea-level, fringing the Arctic shores of the northern continents, and specially characteristic in Siberia (q.v.). The soil remains frozen to a great depth all the year round, thawing superficially when the snow melts in summer, and becoming covered with coarse moss and dwarfed Arctic plants.

(3) *Arid wastes*, or deserts in the popular sense of the word, occur mainly in two zones encircling the world, and corresponding to regions of minimum rainfall (see CLIMATE). The more extensive extends from near the equator in an east-north-east direction across the whole breadth of North Africa, as the Great Sahara, Libyan and Nubian deserts, over the peninsula of Arabia, through Persia, Turkestan, the Gobi or Shamo Desert, in about 52° N. lat., to the Pacific Ocean (see ASIA). The great Indian Desert in the Punjab is the only extension of this belt south of the Himalayas. The ring is completed by the Great Basin of North America in 40° N. lat. The southern zone, less complete, comprises the Kalahari Desert in south-west Africa, the interior of

Australia, and small districts in the Argentine Republic and in the Andes. Deserts occur at all elevations, from considerable depths beneath sea-level to many thousand feet above it, and with all varieties of surface, from a flat expanse of sand, where the view for days of travel is bounded by a sharp circle as at sea, to rocky mountain-slopes rent by rough defiles all bare and chiselled by the driving sand. The essential character of an arid waste is its rainlessness, and the scarcity of water on the surface and of water-vapour in the atmosphere. Radiation in the clear air is intense, and desert climate is consequently of an exaggerated continental type. The sand in the Sahara becomes heated to over 150° F. during the day, and chilled below the freezing-point at night, while the diurnal and seasonal extremes in the lofty deserts of Central Asia are much greater. Thus desert-regions are most effective in producing land and sea breezes and monsoon winds in consequence of the marked periodical changes in atmospheric density. Another effect is the Mirage (q.v.), a phenomenon which, combined with the indescribable horror of loneliness that oppresses the occasional traveller, probably accounts for the widespread superstitions peopling deserts, above all other places, with evil and malicious spirits. The dreaded sand-storm or simoom is a kind of tornado or whirlwind which raises the sand in tall rotating columns sweeping over the surface with tremendous velocity. Sand-dunes, sometimes several hundred feet in height, are raised by steady winds, and gradually shift their position, extending the bounds of the desert to leeward. Desert vegetation is extremely scanty, consisting mainly of hard prickly plants of the cactus, euphorbia, and spinifex kinds, whose glazed surface exhales little of the hardly-won moisture. Animal life is correspondingly restricted both in variety and number of individuals. The Camel (q.v.) is *par excellence* the beast of burden for conducting traffic across arid wastes. When an overflowing river, such as the Nile, traverses a desert, the land becomes richly fertile in its immediate neighbourhood, and wherever a spring bubbles up through the sand there is an Oasis (q.v.) bearing palm-trees and grass. Artificial irrigation, especially the sinking of artesian wells, has done much to reclaim tracts of desert for agriculture in the Sahara (see ALGERIA), and to a less extent in Australia.

Geological considerations show that arid deserts are not permanent features of the earth's surface. The most level expanses have once formed part of the ocean-bed, or at least great inland seas. The orographical changes which cut off these seas and created inland drainage areas probably at the same time modified the rainfall of the locality. Excessive evaporation dried up the great lakes, leaving at present a series of diminishing salt lakes without outlet, receiving rivers which dwindle down by evaporation as they flow. The only commercial commodities yielded by deserts are the salts (common salt, borax, sodium carbonate, and sometimes sodium nitrate) left in the dried-up lake-beds. These salt lakes are subject to alternate long periods of desiccation and flooding; during the former the area of the desert extends, during the latter it contracts. These periods have been traced out in the case of the Great American Basin by a series of most interesting researches on the part of the United States Geological Survey.

(4) *Temporary deserts*, or steppe-lands, border the Asiatic deserts to the north and west. The saline steppes of the Caspian are true arid wastes; but the typical steppes in South Russia are luxuriantly clothed with verdure and flowers in spring. In summer they form a dusty plain of withered herbage, and in winter are wind-swept wastes of snow. The grassy *llanos* of the Orinoco present

a similar desert appearance in the dry season; in the wet season they are inundated marshes which burst into blade and bloom as the water subsides. The *pampas* of the Plate river-system under similar but less marked seasonal changes form a natural transition to the fertile prairie lands which, although naturally treeless, are always richly grassed.

**Desertas**, a group of three rocky islets in the Atlantic Ocean, to the SE. of Madeira, visited at certain seasons of the year by fishermen and herdsmen.

**Desertion** from the army or navy is the crime of absence without leave, coupled with the intention of not returning to the service, or of avoiding some important duty, such as embarkation for a foreign station or aiding the civil power, however short the time of absence or the distance to which the absentee may have gone. Under the Army Act of 1881 the very common offence of quitting one regiment to join another (formerly charged as both 'desertion and fraudulent enlistment'), inasmuch as it proves no intention to leave the service, is punishable by Court-martial (q.v.) as fraudulent enlistment only, but in the same way as desertion when not on active service—viz. by imprisonment up to two years for a first offence, and penal servitude for not less than five years for a second or subsequent offence, together with forfeiture of service, medals, &c., to which may be added stoppages of pay for loss of kit, and discharge with ignominy. By thus distinguishing between desertion and fraudulent enlistment, the number of soldiers annually convicted of the former crime has been reduced by one-half; short service, the abolition of Bounty (q.v.) on enlistment, and better education have had the effect of still further reducing this number. Beyond a published description of all absentees and deserters, recruiting officers have no means—such as formerly existed, when tattooing with the letter 'D' (erroneously called Branding, q.v.) always formed part of the sentence—of detecting a man who has been convicted of this crime and discharged with ignominy, or who endeavours fraudulently to re-enlist. Thus individual men often join five or six regiments, deserting immediately from each in turn and selling their kits. When a soldier has been absent without leave for twenty-one days, a Court of Enquiry is held, with evidence taken on oath, and its record is admitted as evidence in any future court-martial.

Desertion, or attempting to desert, when on active service, or under orders for active service, is much more rare, and is punishable with death. So is the crime of inducing a soldier to desert under those circumstances; and a civilian who is convicted of it, if subject to military law because accompanying a force in the field, as a newspaper correspondent or a camp-follower, is liable to this punishment. When not subject to military law, six months' imprisonment with hard labour may be awarded by any court of summary jurisdiction to a civilian who induces or assists a soldier to desert. Deserters from the United States army forfeit all pay and allowances due at the time of desertion. If in time of war, the penalty is death; in peace, they suffer such penalty as a court-martial may direct.

Desertion is equally a crime when committed by a seaman of the royal navy. A sailor absent from three successive musters is a 'runaway'; and when discovered and brought back, he is punished by a deduction from his pay. If his absence is continued, it amounts to desertion. All harbouring of deserters by other persons is punishable. In the navy of the United States, a temporary absence without leave with an apparent intention of return-

ing to duty, is regarded as 'straggling,' but an absence of ten days constitutes desertion. In either case the commanding officer decides the points, and causes the proper entries to be made on the ship's books.

**Desertion of the Diet.** See DIET.

**Desertion of Wife and Children.** See HUSBAND AND WIFE, PARENT AND CHILD.

**Desiccants**, in Medicine, are substances with astringent properties, which are serviceable in checking secretion and exhalation.

**Desiccation** is the process of drying by the employment of heat, dry air, or chemical agents which have an affinity for water. Examples of the class of *desiccants* or drying substances are fused chloride of calcium, quicklime, fused carbonate of potash, and oil of vitriol. The latter is employed by being placed in a separate vessel near the substance to be dried, and under a bell jar.

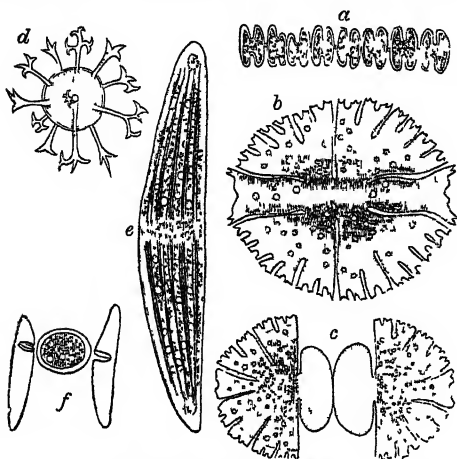

Not a few of the lower animals are said to be able to endure drying up without losing the power of recovery. Some of the Protozoa form protective sheaths or cysts from which they emerge on the return of moisture. Nematodes or thread-worms (paste-eels) have been known to revive after fourteen years' desiccation, but trials beyond this limit were unsuccessful. With those animals the interesting fact has been noticed that the longer the period of desiccation, the longer the time required for recovery. Rotifers are also described as reviving after prolonged and thorough desiccation, but experiments have shown that, in the case in question at least, only the associated eggs retained their life. The eggs rapidly developed on the return of moisture, but the adult organisms proved to be really dead. The bear-animalcules or Tardigrades have been thoroughly desiccated and even heated to a high temperature without, it is said, losing power of revivification. A state of latent life is also assumed in consequence of cold, absence of stimulus, &c., and a relative quiescence occurs naturally in hibernation, or pathologically in trance. Among the lower plants, resting spores, &c., may survive desiccation; and, among the higher, seeds are well known to have a similar power. See HIBERNATION, INSECTS, LATENT LIFE, MUD-FISHES, ROTIFERA, SLEEP, &c. For the desiccation of land-areas, see DESERT, ASIA.

**Desira'de**, a small island of the West Indies, belonging to France, and lying 4 miles E. of Guadeloupe, with an area of 10 sq. m., and a population of about 1600, engaged in fishery and the cultivation of cotton.

**Desman.** See MUSK RAT.

**Desmids** (*Desmidiaceæ*) are a family comprising over 2000 species (700 British) of freshwater unicellular conjugate Algae, related to such filamentous genera as *Zygnema* and *Spirogyra*. Desmids usually occur as free individual cells, varying in length from  $\frac{1}{16}$  to  $\frac{1}{4}$  inch, endowed with movement and floating or associated with larger aquatic plants. The individuals in some species are united into filaments (fig. a), while a few occur in gelatinous masses in water or on wet rocks. They are remarkable for their peculiar symmetry and diversity of form, which, with their ornamented and indented cell-walls and large, frequently lobed, brilliantly green chloroplasts, render them microscopic objects of great beauty. In the typical species each cell consists of two symmetrical halves termed semicells, often partially separated by a shallow or deep constriction (figs. b, c), although elongated forms (fig. e) may be unconstricted. The cell-walls are usually of a complicated structure, consisting of a delicate inner

layer of cellulose, and a stronger outer layer, through which pass numerous pores; other external ornamentations occur as variously shaped lines, dots, bosses, horns, and spines. Multiplication occurs by the division of the nucleus and protoplasm of each semicell, a daughter semicell

Desmids (mostly  $\times 100$ ):

a. Continuous filament of *Sphaerosoma vertebratum*; b. *Mictasterias rotata*; c. *M. denticulata*, dividing; d. Zygosporangium of the same; e. *Closterium lunula*; f. *Closterium* in conjugation.

from each being protruded at the median constriction (fig. c). The new half-cells grow, slowly or quickly, and assume the exact form and size of the parent semicells, pushing the old ones apart as they develop. Each of the two new desmids thus produced consists, therefore, of an old and a new semicell. Sexual reproduction occurs by the conjugation of two individuals, a zygosporangium forming between them (fig. f). The wall of the mature spore may be variously ornamented (fig. d); ultimately it produces two or more new individuals. In many respects desmids exhibit close analogy and possibly affinity with Diatoms (q.v.).

See J. Ralfs, *Brit. Desmidiaceae*; Pritchard, *Infusoria*, 4th ed.; Cooke, *Brit. Desmids*; West and West, *Brit. Desmidiaceae*, 6 vols.; and most works on the microscope.

**Desmodium Gyrans.** See TELEGRAPH PLANT, and PLANTS (MOVEMENTS OF).

**Des Moines**, the capital and largest city of Iowa, is situated on the Des Moines River, at the mouth of the Raccoon River, 340 miles W. of Chicago. Founded in 1846, the city has a fine state-house, a marble post-office and court-house, a university, and a state library. Half-a-dozen bridges over the two rivers connect the different parts of the town, and there is a public park, with fine groves of forest trees. Extensive coal deposits surround the city, large quantities being mined within the city limits. The shipping trade is extensive and important, and the manufactures are large and varied, including typewriters, bricks, sewer-pipes, white bronze, agricultural implements, and others. There are large pork-packing establishments, and the assurance business is among the greatest in the country. Pop. (1880) 22,408; (1900) 62,139; (1910) 86,368; (1920) 126,468.

**Desmoncus**, an American genus of climbing palms which represent the rattans (*Calamus*) of East Indian forests.

**Desmond**, EARLS OF, a line formerly all-powerful in the south-west of Ireland, numbered fifteen of the title, dating from 1329, and ended

with that Fitzgerald who rebelled against Elizabeth's government, sacked Youghal by night and murdered the people, and was proclaimed a traitor in 1579. He escaped the fate of the Spanish garrison at Smerwick (1580), and carried on the struggle for some time; but driven at last from his strongholds, he wandered about for over two years, and was finally killed, in 1583, in a cabin in the Kerry mountains, where his hiding-place had been betrayed to the English.

**Desmoulins**, CAMILLE, a famous figure in the French Revolution, was born 2d March 1760, at Guise, in Picardy. He studied law along with Robespierre at the Collège Louis-le-Grand, in Paris, but never practised owing to a stutter in his speech. His mind early became filled with lofty but confused notions of classical republicanism, which found vent on the eve of the Revolution in his pamphlets, *La Philosophie au Peuple Français* (1788) and *La France Libre* (1789), the latter published the day after the insurrection which destroyed the Bastille, in promoting which its author played a conspicuous and dramatic part. His next writing was the brilliant and vigorous *Discours de la Lanterne aux Parisiens*, which procured him the sinister title of 'Procureur-général de la lanterne.' In November 1789 he issued the first number of the *Révolution de France et de Brabant*, which appeared weekly until July 1792 (No. 86), and which for combined brilliancy of wit and irony, polemic force, power of sarcasm, and grace of form, remains without an equal in the whole range of journalism. His next paper, the *Tribune des Patriotes*, died in its fourth number. Camille had been a member of the Cordeliers' Club from its foundation, and early clung to the mighty Danton in an affectionate friendship of singular intensity. Elected by Paris to the National Convention which followed immediately after the march of the mob on the Tuileries (August 10), he voted with his party for the death of the king. In the struggle between the Girondists and the Mountain he took an active part, and in May 1793, urged on by Robespierre, published his truculent *Histoire des Brissotins*, with a gay heedlessness which had a terrible success, and caused him soon afterwards the most profound remorse. On the 5th December of the same year came out the *Vieux Cordelier*, a thrilling and eloquent expression of Camille's and Danton's longing for clemency. Robespierre, at first favourable, took fright at the reception of the papers after the third, and abandoned his old fellow-student to a fate of which his fragments of writings, as well as his letters and his young wife's journals and scrap-books, show us he had already a strange presentiment. It was only in December 1790, after three years of love, that her father had permitted him to marry the bright young Lucile Duplessis, a girl of a fanciful and romantic temperament, then hardly twenty years old. Their brief married life was one of singular happiness, and in their deaths they were hardly to be divided. Meantime Hébert and his party assailed him, and his freedom of wit made fatal enemies of Billaud-Varennes and Saint-Just. The last number of the *Vieux Cordelier* that appeared in its author's lifetime was the sixth (February 1794). Already he had been twice accused before the Jacobin Club, when on the night of the 30th March 1794 he was arrested with Danton and a group of their friends and partisans. When formally asked his age before the Revolutionary tribunal, he replied: 'J'ai l'âge du sans-culotte, Jésus, c'est-à-dire trente-trois ans, âge fatal aux révolutionnaires.' Camille's sensitive temperament could not face death with the boisterous heroism of the Titanic Danton. But on the scaffold he recovered the courage that had deserted him in the prison and on

the tumbril. 'Thus then,' he said, as he looked at the blood-stained guillotine, 'the first apostle of Liberty ends;' and with the words, 'Oh my poor wife!' he laid his head under the fatal knife. A fortnight later Lucile followed him to the same doom, dying with the heroic courage of the martyr. Their story is nobly told in Jules Claretie's *Camille Desmoulins and his Wife* (trans. Mrs Hoey, 1876). See Lives by Godart (1889), Claretie (1908), and Miss Methley (1915).

**Desna**, a river of Ukraine, flowing south-eastward to Biansk, and then south-westward till it falls into the Dnieper, almost opposite Kiev. It has a course of 550 miles, navigable nearly throughout, and is the channel of a large trade; its low banks are frequently inundated in spring. Its chief affluents are the Seim and the Snov.

**De Soto**, FERNANDO, Spanish discoverer, born at Jerez de los Cavalleros, in Estremadura, about 1496, of a good but impoverished family, accompanied Pedrarias Davila to Darien in 1519, served on the expedition to Nicaragua in 1527, and afterwards assisted Pizarro in the conquest of Peru, returning to Spain with a fortune of 'an hundred and fourscore thousand ducats.' Charles V. now gave him permission to conquer Florida at his own expense, and appointed him governor of Cuba; and in 1538 he sailed from San Lucar with a richly equipped company of 600 men, 24 ecclesiastics, and 20 officers. The fleet anchored in the bay of Espiritu Santo (now Tampa Bay) on 25th May 1539; the ships were sent back to Cuba, and the long search for gold was begun. For three years, harassed by hostile Indians, lured onward by reports of wealth that lay beyond, the ever-decreasing company continued their toilsome march over a route that cannot now be very clearly traced. In 1541 the Mississippi was reached and crossed, and the third winter was spent on Washita River. Returning to the Mississippi in the spring, De Soto, worn out by disappointments, died of a fever on its banks in June 1542; and that his death might be concealed from the Indians, his body, wrapped in a cloak, was lowered at midnight into the waters of the great stream he had discovered. In the following year his companions, reduced to half their original number, sailed down the river in seven frail boats, and finally reached the town of Panuco, in Mexico. See Lives by Wilmer (1858), Abbott, Shipp, and Cunningham-Graham (1903).

**Despard**, EDWARD MARCUS, conspirator, was born in Queen's County, Ireland, in 1751, and at fifteen obtained an ensigncy. From 1772 till 1790 he did good service in the West Indies, both as a soldier and as superintendent of the new territory of Yucatan. He was then recalled on the most frivolous charges, which for two years were kept hanging over him; nor, when they were dismissed, could he get the least compensation. His complaints brought him two years' imprisonment (1798-1800), on his release from which he engaged in a crackbrained conspiracy to assassinate the king and to seize the Tower and Bank of England. For this, with six of his associates, he was drawn on a hurdle, hanged, and beheaded, 21st February 1801. —His brother, JOHN DESPARD (1745-1829), British general, was present at twenty-four engagements, mostly during the American War of Independence.

**Despauterius**, the Latinised name of JAN VAN PAUTEREN (1460-1520), a Fleming, born at Ninove near Brussels, who studied at Louvain, and taught there and at s'Hertogenbosch, Comines, &c. His Latin grammar was in general use in France till the Port-Royalists superseded it, and in Scotland till the Reformation.

**Despenser**, HUGH LE. See EDWARD II.

**Des Périers**, BONAVENTURE, one of the most interesting prose-writers of the Renaissance period in France, was born at Autun in Burgundy about the year 1500. Little is known regarding his life beyond the fact that he was a member of the court of men of letters assembled by Marguerite of Navarre. In 1537 he published the *Cymbalum Mundi*, a work in dialogue, in which, under the pretence of attacking the superstitions of the ancients, he satirised the religious beliefs of his own day. The book raised a storm of indignation, against which Marguerite seems to have been powerless to shield Des Périers, who, rather than fall into the hands of his persecutors, is said to have killed himself in 1544. His *Nouvelles Récréations et Joyeux Devis* were published in 1558. They consist of 129 short stories, both comic and romantic, and are admirable examples of narrative art, though the laxity of the Renaissance is frequently apparent in the writer's choice of subjects. The style is vivacious and elegant; indeed, Des Périers is one of the greatest masters of French prose whom the 16th century produced. Besides writing the *Cymbalum Mundi* and the *Joyeux Devis*, it is by many critics believed that Des Périers was part author of the *Heptameron* associated with the name of Marguerite. See MARGARET OF NAVARRE, and the edition of Des Périers' works by Lacour (2 vols. Paris, 1856).

**Despoblado** (Span., 'desert'), a treeless, uninhabited plateau, nearly 10,000 feet above the sea, on the Bolivian and Argentine frontier.

**Desportes**, PHILIPPE (1546-1606), French poet, born at Chartres, went as secretary with the Bishop of Puy to Italy, where he studied Petrarca and Ariosto, and to Warsaw with Anjou, who as Henry III. of France continued to be his patron. Desportes greatly influenced the English Elizabethans, especially the sonneteers.

**Despoto Dagh**. See RHODOPE.

**Despréaux**. See BOILEAU.

**Dessalines**, JEAN JACQUES, emperor of Hayti, was born about 1758 in Guinea, Africa, and was at an early age imported thence into Hayti as a slave. He was bought by a French planter, whose name he afterwards assumed, and early became a prominent leader in the insurrection, second only to Toussaint L'Ouverture. In the struggle with the French he was always distinguished by his agility and swiftness of movement, as well as by his fearlessness and ferocious cruelty. After the first compromise he became governor of the southern part of the island, but soon began the war anew, and, after infamous cruelties, compelled the French to evacuate the island in October 1803. He was created governor in January 1804, when the people of the island declared themselves independent, and on 8th October had himself crowned as emperor of Hayti, under the name of Jean Jacques I.; but his despotism, debauchery, and cruelty soon alienated the sympathy and support even of those who had been his firmest adherents. In 1806, while trying to repress a revolt, he was cut down by Christophe (q.v.), who succeeded him as emperor of Hayti.

**Dessau**, capital of Anhalt, on the Mulde, not far from its junction with the Elbe, 70 miles SW. of Berlin. It is in general well built. Among the principal buildings are the ducal palace, a noble structure, built in 1748, and improved in 1875, with a valuable picture-gallery and library; a town-hall, an elegant theatre, and several churches. The *Philanthropin* of Basedow (q.v.) was here. The manufactures are sugar, woollen cloth, machinery, carpets, and there is a large trade in grain. Moses Mendelssohn was a native. Leopold, Prince of Anhalt-Dessau (1676-1747), a famous soldier in the wars of the 18th century, is

popularly known as *der alte Dessauer* ('the old Dessauer'); his statue adorns the market-place. Pop. 58,000.

**Desterro.** See FLORIANOPOLIS.

**Destouches**, PHILIPPE, one of the chief comic dramatists of France in the 18th century, was born at Tours in 1680. He wrote seventeen comedies, two of which, *Le Philosophe Marié* (1727), and *Le Glorieux*, his masterpiece (1732), are of a very high order of excellence. He died in 1754. His characters are truthfully drawn, and his plots interesting. In his style he imitated Boileau rather than Molière, and his verse has occasionally a happy epigrammatic turn. In his language he avoided the freedom of the older comedians, but the moral tone of his plays cannot be described as high.

**Destroyer.** See NAVY.

**Destructors.** See SEWAGE.

**Desuetude**, in Scots law, that repeal or revocation of a legal enactment which is effected not by a subsequent contrary enactment, but by the establishment of a contrary use, sanctioned by the lapse of time and the consent of the community. Neither the word nor the idea attached to it is familiar to the law of England—where the corresponding term is *non-user*. The rule in England is, that a statute once formally enacted by the legislature, remains in force, however unsuited it may be to the altered conditions of society, till it be repealed by another statute. The repeal may be by implication, but here the law watches with a jealous eye. Such repeal 'is to be understood,' says Blackstone, 'only when the matter of the later statute is so clearly repugnant that it necessarily implies a negative.' So far was this principle carried, that it was formerly the rule, that if a statute repealing another was itself repealed afterwards, the first statute was revived without any formal words for that purpose. But this rule was changed by 13 and 14 Vict. chap. 21. In Scotland, an opposite principle prevailed, and it is still held that acts of parliament made before the Union may lose their force by disuse, without any express repeal, or 'go into desuetude,' as it is commonly said. The same may be said of the general orders (Acts of Sederunt, as they are called) of the Court of Session. But by desuetude is meant something more than mere non-use for a period of time, however great. There must be contrary use of a positive kind, inconsistent with the statute, and of such a kind as to prove the altered sense of the community; there must, in short, be consuetudinary law in a negative sense; and the so-called desuetude thus amounts to a repeal of statute law by consuetudinary law.

Both rules are liable to objections. The result of that followed in England has been that statutes have remained on the statute-book without formal repeal after their enforcement had become morally impossible. A curious example of this occurred in the early part of the 19th century, in which one of the parties to an ordinary civil suit challenged his adversary to 'judicial combat,' founding his claim to do so upon an unrepealed statute, and it was held that in point of form his right could not be disputed (see DUELLING). But since 1869 the English statutes have been by the Statute Law Revision Acts weeded to a great extent of all obsolete and inconsistent enactments. The rule in Scotland is the same as the English for statutes made since the Union; but for older Scottish statutes it is difficult when contrary use justifies the plea of desuetude.

**De Tabley**, JOHN BYRNE LEICESTER WARREN, LORD (1835-95), educated at Eton and Christ Church, Oxford, was called to the bar at Lincoln's Inn in 1859, unsuccessfully contested

Mid-Cheshire as a Liberal in 1868, and succeeded his father as third baron in 1887. He published eight volumes of poetry (1863-75), two novels (1868-69), and a *Guide to Book Plates* (1880). *Philoctetes* and *Orestes* were powerful dramas. A selection appeared in 1893; *Orpheus in Thrace* and other poems in 1901.

See memoir by Sur M. Grant Duff prefixed to his *Flora of Cheshire* (1899), Gosse's *Critical Kat-Kats* (1896), and Professor Walker's biographical sketch (1903).

**Detaille**, JEAN BAPTISTE ÉDOUARD (1848-1912), military painter, was born at Paris, studied under Meissonnier, but, joining the army in 1870, found endless material for a long series of impressive pictures of the glories and horrors of war.

**Detective.** See POLICE.

**Determinants**, in mathematical analysis, a symbolical method by which, *inter alia*, the solution of equations becomes a matter of mere inspection. The development of the method is due mainly to the French mathematician Cauchy (q.v.). The determinant is the sum of all the products that can be formed from a group of quantities arranged as columns and rows in a square block; each product containing as a factor one from each horizontal row and one from each column; the sign being plus or minus, according as the arrangement of rows from which it is taken requires an even or odd number of transpositions to reduce it to the arrangement in the square. The deter-

minant of the third order  $\begin{vmatrix} a & b & c \\ a' & b' & c' \\ a'' & b'' & c'' \end{vmatrix}$  is equal to

$a b' c'' - a b'' c' + a' b' c - a' b c'' + a'' b c' - a'' b' c.$

**Determinism.** See WILL.

**Detmold**, capital of the German republic of Lippe, on the Werre, 47 miles S.W. of Hanover. The chief buildings are the old castle, the modern palace, and the theatre. Detmold has also a museum, a public library, a hospital, a gymnasium, and other schools. There are manufactures of tobacco, cards, and carved work in wood and stone, and breweries. On a hill 2 miles from Detmold is a colossal statue of Arminius (q.v.). Pop. 15,000.

**Detonation.** See FLAME, GUN-COTTON.

**Detritus**, applied in Geology to accumulations formed by the disintegration of rocks, may consist of angular and subangular debris, or of more or less water-worn materials, such as gravel, sand, or clay, or an admixture of these. See PLEISTOCENE.

**Detroit**, the chief commercial city and port of entry of Michigan, and seat of justice of Wayne county, is situated on a river of its own name ('the Dardanelles of the New World'), and is about 125 miles by water, or 178 by land, N.W. of Cleveland, Ohio, with which it is connected by daily steamers and by railway lines. Railways also connect Detroit with Chicago, 284 miles distant, and direct lines extend to all the principal places in Michigan. By way of Windsor on the opposite side of the river, the Grand Trunk Railway of Canada affords direct communication with the cities of the Dominion, and a large number of vessels ply between this city and the other ports on the Great Lakes. Detroit is substantially built upon rising ground, its streets are broad, well paved, and shaded with trees. It is well supplied with the best of water, pumped from the river by massive engines. Its fire and police departments are excellent, as also is the system of public schools and colleges. It has a public library and several educational libraries. The chief industry is automobile-building. There are besides immense railway-car works and iron-working establishments, numerous tanneries, and factories for tobacco, shoes, stoves, drugs, &c., and there is a large and increas-

ing trade in grain, flour, live-stock, lumber, wool, pork, and copper. The harbour is excellent, and much of the enormous shipping trade of the great lakes emanates from or otherwise benefits this city. About three-fourths of the total trade is with Canada, and the larger part of the remainder with Britain. The river is open for navigation about eight months in the year. The streets are regular, and many of them planted with trees. The public buildings embrace a Catholic cathedral and numerous churches of almost all denominations, a city-hall, a Board of Trade building, a convent, a United States marine hospital, &c. Numerous daily newspapers and weekly and monthly periodicals are published here, of which several are in German. Detroit was settled by French colonists as early as 1710, was transferred to the British in 1763, and in 1796 passed to the United States. It was incorporated as a city in 1824, and till 1847 was capital of the state. Pop. (1870) 79,577; (1890) 205,876; (1910) 465,766; (1920) 993,678.

**Detroit River**, so called, upon the north-western bank of which stands the city of the same name, is the strait through which the waters of Lake St Clair, and of the great upper lakes of the St Lawrence system, flow into Lake Erie, and thence to the Atlantic Ocean. It is about 20 miles in length, with a depth sufficient to float the largest vessels, and at Detroit forms an excellent harbour for shipping.

**Dettingen**, a village of Bavaria, on the Main, 7 miles NW. of Aschaffenburg, is noted as the scene of a battle during the war of the Austrian Succession, when, on 27th June 1743, George II. (q.v.) of England, commanding English, Hanoverians, and Austrians, defeated the larger French army under the Duc de Noailles. This was the last time a king of England took the field in person. —There is another Dettingen 10 miles E. of Reutlingen in Württemberg.

**Deucalion**, son of Prometheus, and husband of Pyrrha. When Zeus had resolved to destroy the race of men by a flood, after the treatment he had received from Lycaon, Deucalion built an ark or ship, in which he and his wife floated during the nine days' flood which drowned all the other inhabitants of Hellas. On the subsidence of the waters the ark rested on Mount Parnassus. To repopulate the world Deucalion and Pyrrha were told by the goddess Themis to throw behind them the bones of their mother. This they did with the stones of mother-earth, and from those thrown by Deucalion sprang up men, and from those by Pyrrha, women.

**Deuteronomy** (from the Greek *deuteronomos*, 'the second law,' or, according to the use of the word in the Septuagint, 'a duplicate of the law'), the fifth book of the Pentateuch. Its contents comprise: (a) A review of the history of Israel during the wanderings in the wilderness, chap. i.-iv. (b) An address of Moses to prepare the people for the reception of the law, chap. v.-xi. (c) The law itself, chap. xii.-xxvi. This constitutes the kernel of the book. (d) An epilogue enforcing the law by the promise of blessing for its fulfilment and the threat of curses for its infraction, ending up with an account of the death of Moses, chap. xxvii.-xxxiv. Modern scholars are generally agreed that the nucleus of the book represents the law which was discovered by Josiah in 621 B.C. It must have originated during the period which intervenes between the earlier prophets—e.g. Amos and Hosea—and Jeremiah. In religious tone and theological ideas it has many points of resemblance to the last named. There is more divergence of opinion as to the date at which the book was completed, but it was probably

between 621 and 586 B.C. Deuteronomy is characterised throughout by a religious fervour and a prophetic zeal which are in striking contrast to the tone of Leviticus; and it represents a higher spiritual level than any other book in the Pentateuch. Its legislation stands half-way between the Law of the Covenant in Exodus and the Priestly Code which is embodied in Leviticus (see BIBLICAL CRITICISM, PENTATEUCH). The critical problems connected with the book are fully discussed in Driver's *Introduction to the Literature of the Old Testament*, and in the articles in *Hastings's Bible Dictionary*, and the *Encyclopædia Biblica*. The most complete commentary in English is that of Driver (*International Critical Commentary*).

**Deutsch**, EMANUEL OSCAR MENAHEM, was born of Jewish parents at Neisse, in Silesia, 28th October 1829. His education was begun at the local gymnasium at the age of six, continued by his uncle, a learned rabbi, to whom he owed his mastery of Hebrew and Chaldee literature, and finally pursued at the university of Berlin. In 1855 he came to an appointment in the library of the British Museum, where 'for fifteen years with mighty ardour and magnificent industry he studied and wrote, enjoying life among his friends, yet more among his books; shedding sunshine wherever he went, attracting and attaching not a few.' He is best known by his brilliant article on the *Talmud* in the *Quarterly Review* (1867), to which he also contributed an article on *Islam* (1869). He wrote excellent articles on the *Targum* and the *Samaritan Pentateuch* for Smith's *Dictionary of the Bible*, and was a valued contributor to the first edition of *Chambers's Encyclopædia*, for which he wrote nearly two hundred articles. He had a remarkably vigorous and poetic English style.

**Deutschbrod** (Czech, *Brod Německý*), a town of 9000 inhabitants, in the south-east of Bohemia. Here in 1422 the Hussite general Ziska defeated the Emperor Sigismund.

**Deutz**. See COLOGNE.

**Deutzia**, a genus of Saxifragaceæ, natives of the north of India, China, and Japan. Some are favourite greenhouse plants in Britain, producing abundance of beautiful white flowers. The commonest species (*D. scabra*) is frequent in shrubberies.

**Deux-ponts**. See ZWEIFBRÜCKEN.

**Deux-Sèvres**. See SEVRES.

**De Valera**, EAMONN, born 14th October 1882 in New York, of Spanish and Irish parentage, was brought up in Ireland, studied at the Royal University, where he graduated in Arts and in Science, and taught mathematics in various colleges. He played a distinguished part in the Easter rising of 1916, but surrendered by order of Padraic Pearse. He was sentenced to death, but liberated, and in 1917 was elected member of parliament for East Clare, and, by the Sinn Féin convention, President of the Irish Republic. Imprisoned again in 1918 with other Sinn Féin leaders, he escaped from Lincoln jail in 1919, and went to America, where he strove hard for his cause. When the treaty with Great Britain was submitted to Dáil Éireann Mr de Valera vehemently opposed it as a compromise, resigned his presidency, was defeated by Mr Arthur Griffith on seeking re-election (1922), and took up arms (1922-23) against the Free State. He was arrested in August 1923, released in July 1924.

**Devanāgarī** (lit. 'town-script of the gods'), the character most widely understood by Hindu scholars, in which Sanskrit works are usually printed, unless when in Roman letters. See SANSKRIT, ALPHABET, WRITING.

**Devaprayaga** (better *Deoprayag*), a village in the district of Garhwal, United Provinces of

India, on a mountain side, 2266 feet above the sea, in the fork of the Alaknanda and the Bhagirathi, which join to form the Ganges (q.v.). Devaprayaga possesses a notable temple, and is a favourite place of pilgrimage for the Hindus.

**Development** is a term used in several special or technical senses. In mathematics it means the process by which any mathematical term is changed into another of equivalent value or meaning: in geometry specifically the unrolling of a cylindrical or conical surface, the unbending of any curved surface into a plane, is called development. The word is sometimes used of the whole field of Embryology (q.v.) and of Evolution (q.v.), but is specially applied rather to the theories of Lamarck (q.v.) than to the Darwinian Theory (q.v.); see also the articles BIOLOGY, HEREDITY, MAN, VARIATION, WEISMANN. The history of every science, art, or invention is a history of progress and development. (See ANTHROPOLOGY, ART, and the relevant sections of the articles on sciences, &c., throughout the work.) The word has its own meaning in Photography (q.v.); in music the development of a musical phrase or subject is the unfolding of its capacities by modification of melody, harmony, tonality, rhythm, &c. (see SONATA); and development of doctrine is dealt with in the articles DOGMA (q.v.), CHRISTIANITY, NEWMAN, and ROMAN CATHOLIC CHURCH.

**Deventer**, an old Hanse town of Holland, in the province of Overijssel, on the Yssel, 11 miles NNW. of Zutphen by rail. It has an 11th century cathedral and a fine town-house, and manufactures iron, carpets, cotton, tobacco, beer, and gingerbread. Thomas à Kempis and Erasmus were educated at Deventer. Pop. 32,000.

**De Vere**. See VERE.

**Deveron**, a beautiful salmon river of Aberdeen and Banff shires, rising 3 miles SW. of the Buck of Cabrach, at an altitude of 1847 feet, and thence winding 62 miles north-eastward, till it falls into the Moray Firth at Banff. See *Lauder's Moray Floods* (1830).

**Deviation**. See COMPASS.

**Device** (late Lat. *divisa*, 'a drawing'), if in a wider sense, applicable to emblems on shields, such as described by Homer, is, in a more restricted use of the word, a decoration with accompanying legend, assumed by an individual rather than a family, and for the purpose not of publicity, like the badge (with which it has sometimes been confounded), but of mystification, with covert allusion to the circumstances of the bearer. It is, in fact, a rebus or painted riddle, with a legend allusive to it, as the knot borne by Sir Thomas Heneage, of a shape suggestive of a heart, with the inscription 'Fast though untied'; and the heart borne by Lord Latimer, with the legend 'Dieu et ma fiancée.' See BADGE.

**Devil**, THE, and SATAN, the names bestowed by the New Testament and Christian theology upon the supreme impersonation of evil, who is regarded as a real being—the head of the kingdom of darkness, the source of all temptation and sin, and the lord of evil spirits. This conception of Satan is of comparatively late origin. It is not found in the earlier literature of the Old Testament, and only occurs in three of the post-exilic writings—Job, Zechariah, and 1 Chronicles, and even in these it has not yet assumed the fixed and definite characteristics which are so marked in the New Testament and later Christianity. In the older books of the Old Testament God is often described as the source of the evils which afflict men—e.g. the hardening of Pharaoh's heart, the smiting of the first-born—though in some cases the evil results

are attributed to the agency of wicked spirits. We find a very good illustration of the contrast between the earlier and later thought of the Old Testament, when we compare the parallel explanations of David's sin in numbering the people in 2 Sam. xxiv. 1 and 1 Chron. xxi. 1. The Samuel passage reads, 'And again the anger of the Lord was kindled against Israel, and he moved David'; whereas in Chronicles we are told, 'And Satan stood up against Israel, and moved David to number the people.' It is clear from this comparison that what is ascribed to God in the early period is ascribed to Satan in the later, and we may conclude that it was in the period between 700 and 300 B.C. that the figure of Satan was evolved. But even in the book of Job the conception is still indefinite. Satan is described as taking his place in the heavenly court among the 'sons of God,' and suggesting that a test should be applied to Job to find out if his religious devotion is genuine or not. Satan himself is commissioned to apply the test, which takes the form of an infliction of a series of misfortunes. There is nothing in Job to prove the existence of radical antagonism between God and Satan. The most that can be said is that while God is anxious that Job's character should be vindicated, Satan seems to desire to prove that he is a mere time-server. The nearest approach to the New Testament conception of Satan is found in the third chapter of Zechariah, in which Satan is depicted as the adversary and accuser of mankind, anxious to secure the condemnation of Joshua the high priest. There is nothing, however, in this passage, or in the Old Testament as a whole (apart from the hint in 1 Chron. xxi. 1), to show that Satan was regarded as responsible for the sin of the world.

It is in the intermediate period, and more especially in the Apocalyptic literature, that the figure of Satan takes on its New Testament dress. In the book of Wisdom, for instance, the fall of Adam is represented as due to his instigation: 'By the envy of the Devil sin entered the world.' Elsewhere he is described as 'the seducer of the desert,' who tempted Eve to her destruction. The *Apocalypse of Adam and Eve* gives an account of the fall of Satan himself. After Adam had been created in the divine 'image and likeness,' God summoned his angels and bade them 'worship the image of God.' All the rest obeyed, but Satan refused, saying: 'I am his senior in creation; it is his duty to worship me.' For this refusal, God banished Satan and his angels from glory and hurled them down to the earth. A different explanation of the downfall of Satan is given in the *Book of the Secrets of Enoch*: 'And one from out the order of angels, having turned away with the order that was under him, conceived an impossible thought, to place his throne higher than the clouds above the earth that he might be equal in rank to my power. And I threw him out from the height with his angels, and he was flying in the air continuously above the bottomless pit.' It is stated several times in these books that in the ideal kingdom there will be 'no Satan.'

When we turn to the New Testament we find the conception of Satan clear and well-defined. He is called by a variety of names—e.g. Satan (i.e. the adversary), the Devil (i.e. the accuser), 'the prince of demons,' 'the prince of this world,' 'the god of this world,' 'the prince of the power of the air,' 'the tempter,' 'Beelzebub,' 'Beliar' or 'Belial,' 'the enemy,' 'the wicked one,' 'the old serpent.' These titles convey the idea that in the minds of the New Testament writers the Devil was a personal being—the head of a hierarchy of evil spirits who are his ministers and servants,

the originator and instigator of sin and its penalty death, the source of all physical maladies and evil generally, the antagonist of God and man. Jesus is reported to have described him as 'a murderer from the beginning.' 'He stood not in the truth, because there is no truth in him; . . . he is a liar and the father thereof' (John, viii. 44). The evil spirits who torment men are his emissaries, and the casting out of these spirits is represented as a defeat of Satan himself. When the disciples returned from their mission and reported their success in vanquishing these evil spirits, Jesus said, 'I beheld Satan fallen like lightning from heaven' (Luke, x. 18). The ultimate victory of God over Satan is definitely predicted. 'Everlasting fire' has been 'prepared for the Devil and his angels' (Mat. xxv. 41). According to the book of Revelation, he is 'cast into the lake of fire and brimstone' to be 'tormented for ever day and night' (Rev. xx. 10).

The New Testament, therefore, presents us with a complete and comprehensive conception of the Devil as a real personality engaged in active and even violent opposition to the work of Christ, attempting in every way to thwart the grace of God. There is no absolute dualism, as in the Zend-Avesta, where the universe is ruled by two equally-balanced powers—Ormuzd and Ahriman—because the New Testament never for a moment wavers in its intense conviction that God is supreme and omnipotent, but still, for all practical purposes, we are left, for the present at any rate, with a dualism of two contending empires, each under its own king, struggling for the supremacy. Beyschlag has attempted to argue that the demonology of the New Testament is simply poetry which later Christianity turned into prose. The language of the New Testament, however, is too precise and definite to be set aside in such a cavalier fashion. If words mean anything, it is impossible to evade the conclusion that the belief in Satan and the world of demons is an essential element in the teaching of the New Testament. We may, of course, take up another position, and say that this side of early Christian belief reflects the spirit of the age; at that time the belief in Satan, in some shape or form, was universal, and Jesus and his followers upon this point simply adopted the common thought and speech of the age. We must, however, be in possession of overwhelming arguments against the possibility of the existence of Satan before such a position is likely to secure general support.

The New Testament conception was carried over and developed in Christian thought and theology. The Devil plays a much bigger part in the Christian life of the Church during the patristic and mediæval periods than he does in the Christian outlook of recent times. For over a thousand years, right up to the time of Anselm, the popular explanation of the doctrine of the Atonement regarded the Crucifixion as a ransom offered by Christ to the Devil for the redemption of the human race; and even the life of Luther teems with illustrations of the place occupied by the Devil in the conceptions of the time. The moral struggle was regarded as a personal fight with Satan. The well-known incident of Luther 'throwing an inkpot at the Devil' is only an example of the current belief of his day. It is difficult for us to conceive of any one writing in modern times as he wrote on one occasion, 'I heard some one walking on the floor above my head, but as I knew it was only the Devil, I went quietly to sleep.'

It would be interesting to follow out the development of the conception of the Devil in modern literature, but space makes it impossible to do more than refer to Masson's book on *The Three*

*Devils*, in which he compares and contrasts (1) the mediæval devil—a ghoulis figure with horns and hoofs; (2) Milton's Satan—a fallen angel, indeed but still splendid in his fall; (3) Goethe's Mephistopheles, a fine gentleman in appearance, but a scheming trickster at heart.

Since the Reformation, the belief in the Devil has gradually declined. Several causes may be assigned for this change which has come over Christian thought. (1) In the middle ages the belief in the Devil was associated with and made the centre of a great deal of superstition. The superstition has died a natural death and involved the belief in Satan in its fall. (2) The development of science found a natural explanation for the maladies and physical disasters which had previously been attributed to the agency of the Devil. Gradually Satan was ousted from the natural sphere, and as a result lost his place in the moral realm as well. (3) The great characteristic of modern philosophy has been its desire to find a monistic explanation of the universe. The belief in a devil leaves us with a dualism, and there is a widespread feeling that no dualistic hypothesis can possibly solve the ultimate problem. (4) The belief in the existence of a rival power challenging the authority of God has some difficulties for the Christian theologian. The old question, 'Why does not God kill the Devil?' is not easy to answer. The existence of the Devil seems to limit either the omnipotence or the love of God.

The first definite attack on the belief in the existence of the Devil came from Schleiermacher, and his views received the support of Schenkel, Biedermann, Lipsius, Pfeleiderer, and many others. On the other hand, the orthodox position has been strongly affirmed by theologians of such repute as Luthardt, Rothe, Julius Muller, Martensen, and Dörner. The orthodox position to-day relies upon the following arguments: (1) Belief in the existence of the Devil is clearly and definitely involved in the teaching of Jesus and the inspired writers of the New Testament, and we cannot set their authority lightly on one side. (2) The denial of the belief may solve some difficulties, but it raises others in a very acute form. The problem of evil is very greatly intensified in the absence of a devil. 'Nature, red in tooth and claw, With ravine shrieks against the creed.' There would be an easy explanation of many difficulties if we could hold with Tennyson that 'after God had made the world, the Devil came and added mosquitoes.' (3) The philosophical arguments for the existence of Satan are as strong as those for the existence of God. If God is the unity in which all the noblest virtues and ideas inhere, do we not need a unity for the vices and sins of men? (4) The intensity of the moral struggle is only explicable on the hypothesis of the existence of a personal agent, tempting mankind to sin.

See Masson, *The Three Devils*; Roskoff, *Geschichte des Teufels* (1869). The articles on 'Satan' in Smith's and Hastings's *Bible Dictionaries* and the *Encyclopædia Biblica*.

**Devil-fish** is a name used for the Octopus (q.v.), also for the Angler (q.v.), and, in America, for a gigantic species of ray (*Cephalopterus vampyrus*), with very large pectorals. Of the latter a specimen was found in Delaware Bay, 17½ feet by 18 feet, and weighing 5 tons.

**Devil's Bit.** See SCABIOUS.

**Devil's Bridge**, a popular name in most mountainous countries for bridges built over wild chasms. The most notable are (1) a bridge over the Reuss, in the Swiss canton of Uri, 1½ mile W. of Andermatt, on the St Gothard Road, where the river, 4593 feet above sea-level, forms a picturesque

cascade of 100 feet. The granite structure, built in 1830, spanning the stream with a single arch of 26 feet, fell in in August 1888, and traffic was for a time resumed on the old moss-grown bridge 20 feet below, which witnessed some severe fighting between the French and the Austrians and Russians in 1799. (2) A double bridge in Cardiganshire (sometimes called *Pont-y-Mynach*), 10 miles ESE. of Aberystwyth, across a gorge 114 feet deep, and over a mile long, traversed by the Mynach, which makes within a short distance four falls of from 18 to 110 feet. The lower bridge was constructed by the monks of Strata Florida in the 11th century, the upper (20 feet over it) in 1753.

**Devil's Coach-horse** (*Ocypus olens*), a common British and European beetle, in the family Staphylinidae. It has very much reduced wing-covers, and resembles many of its relatives in the habit of curving its posterior body upwards, using the tip to adjust the wings under their covers.

**Devil's Ditch.** See CAMBRIDGESHIRE.

**Devise,** the conveyance of land by Will (q.v.).

**Devizes,** a municipal borough of Wiltshire, near the Kennet and Avon Canal, 50 miles WSW. of Reading, and 20 ESE. of Bath. It lies high at the mouth of Pewsey Vale, between the thinly peopled tracts of Salisbury Plain and the Marlborough Downs. As a town, Devizes owes its origin to a splendid castle built here by Bishop Roger of Salisbury about 1132. It was stormed by Cromwell in 1645, and now is represented by mere fragments. There are two churches with much interesting Norman work; a market-cross (1814), commemorating God's judgment on a perjurer in 1753; a fountain with a statue of Sothorn Estcourt (1879); a good museum; and a large corn exchange (1857). It has manufactures of snuff and malt, and is the seat of an important corn-market. From Henry VIII.'s time till about 1820 Devizes was a great cloth mart. It returned two members till 1867, then one till 1885. Pop. 6000. See *A History of Devizes* (1859).

**Devonian System,** the name proposed by Murchison and Sedgwick for certain slaty and calciferous strata in Devonshire which contain a much more copious and rich fossil fauna than the Old Red Sandstone of Scotland, Wales, and Herefordshire, with which they are believed to be upon the whole contemporaneous. The physical condition under which the strata in Devonshire were deposited differed greatly from those which marked the accumulation of the Old Red Sandstone, and there is still some doubt as to the precise correlation of the two sets of strata. Geologists, therefore, retain both names, and speak of the *Devonian and Old Red Sandstone* system, or *Old Red Sandstone and Devonian* system. See OLD RED SANDSTONE.

**Devonport.** See PLYMOUTH.

**Devonshire,** a maritime county, in the south-west peninsula of England, between the Bristol and the English Channel. Its greatest length is 70 miles; its greatest breadth, 65; and it contains 2600 sq. m., of which about three-fourths are under cultivation. The coast-line approaches 150 miles. The north coast is the boldest, with several hills over 1000 feet. Its chief indentation is Bideford Bay, 18 miles broad and 8 deep, into which fall the Taw and the Torridge. The south coast is also lined with cliffs, chief among them being the bold promontorial district of the Bolt Head and Start Point, the western horn of the great bay of which Portland is the eastern. Tor Bay is 3 by  $3\frac{1}{2}$  miles. Plymouth Sound, the combined estuary of the Tamar and Plym, is one of the finest harbours in the kingdom, the anchorage ground extending 7

miles inland from the breakwater (see PLYMOUTH) by which the outer roadstead is protected. Devonshire is hilly, the most elevated parts being the tablelands of Dartmoor in the south-west, Exmoor in the north-west, running into Somerset, and Blackdown in the east. These are mainly open moorlands. Dartmoor (q.v.) is very rocky; the lower hills grassy. High Willhayse, on Dartmoor (2039 feet), is the highest point. Devonian and Carboniferous strata occupy the greater part of the county; next in importance are the granitic boss of Dartmoor, and the Triassic rocks in the eastern quarter. There are also Archaean rocks, probably Silurian, Greensand, chalk, an Eocene deposit at Bovey Tracey, and many exposures of igneous rocks, intrusive and interbedded. Copper, tin, lead, iron, arsenic, radium, and manganese occur in commercial quantities, with ores of other metals; china, terra-cotta, potter's, and pipe clays; granites, marbles, anthracite, lignite, gypsum, and other earthy minerals. The rivers of Devonshire are numerous. The Tamar, 59 miles, is the longest, and divides Devon from Cornwall; the Exe, 54 miles, which comes next, rises in Somerset. The other leading rivers—the Dart, Teign, Taw, Torridge, and Plym, all from Dartmoor, have estuaries of commercial importance, as have also the Exe and Tamar. The red deer still run wild on Exmoor, and are hunted.

The climate of Devon, especially in the south, is mild and humid, and not liable to great extremes. Hence, several of the towns on the southern and eastern coasts have become famous as health-resorts—notably Torquay; and, on the north coast, Ilfracombe. Myrtles and aloes commonly flourish in the open air; and in specially favoured spots oranges and lemons, with a little protection, will thrive and fruit. The rainfall on Dartmoor is much greater than elsewhere in Devon, and the winters colder and more bracing. The climate is so invigorating, however, that the Moor is rapidly growing into repute as a summer sanatorium, and that the convict prison is regarded as a health-station. The county is most fertile, especially in the South Hams, and on the 'red land' of the Vale of Exeter. The pastures are very rich, and dairy-farming and cattle-breeding are prominent in its agriculture. The red Devon cattle are one of the leading breeds; and the sheep and ponies of Dartmoor and Exmoor have more than a local reputation. 'Clotted cream,' produced by scalding, is a special product almost confined to Devon and Cornwall. There are extensive orchards, from which great quantities of cider are made; and various fruits are largely cultivated in special localities and sent to London and the Midlands by rail. The fisheries are extensive and valuable, the chief centres being Plymouth and Brixham. Though in the main agricultural, Devon has a varied industrial character. Mining and quarrying and clay-working are of considerable importance; and the manufactures include serges, lace, gloves; extensive potteries; manure, chemical, and soap works; paper-mills, breweries, and distilleries. The chief towns are the city of Exeter, Plymouth (including Devonport and Stonehouse), Torquay, Paignton, Barnstaple, Newton Abbot, Exmouth, Ilfracombe, Teignmouth, Tiverton, Bideford, Brixham, Dartmouth. Pop. (1921) 709,488. Under the Representation of the People Act of 1918 Exeter returns one member, Plymouth three, and the rest of the county is divided into seven single-member constituencies.

Devon adds to singular landscape charms anti-quarian attractions of a most comprehensive and varied character, prehistoric and mediæval. The Romans had little to do with it beyond Exeter, which was an important station; the Saxons did not conquer it until the reign of Cynewulf; the Danes ravaged it in the 9th and 10th centuries,

though they were at first repulsed with heavy loss; it was the scene of the western rebellion for the restoration of Roman Catholicism in 1549; Plymouth was the headquarters of the fleet which defeated the Armada in 1588, and the chief mainstay of the parliament in the west of England in the conflict with Charles I.; Brixham was the landing-place in 1688 of William of Orange. No county save Middlesex has given birth to so many eminent men—Raleigh, Drake, Hawkins, Marlborough, Monk, Coleridge, Hooker, Sir Joshua Reynolds, John Davis, Sir Humphrey Gilbert, Sir Richard Grenville, Bishop Jewell, Gay, St Boniface, Newcomen, Wolcott, Kingsley, John Ford, among them.

**Devonshire, DUKE OF.** See CAVENTISH.

**Devrient, LUDWIG** (1784–1832), was a great actor of Shakespearian characters.—His three nephews were also eminent actors—Carl August (1797–1872), husband of the *diva* Madame Schröder-Devrient (1805–80); Philipp Eduard (1801–77), a baritone singer as well as actor, who wrote plays and a history of the German theatre (1848–74), and with his son Otto (1838–94) edited Shakespeare; Gustav Emil (1803–72), the most gifted of the three brothers.

**De Vries, ADRIAAN** (1560–1627), sculptor, born at the Hague, did his best work at Augsburg.

**De Vries, HUGO**, born at Haarlem in 1848, became professor of vegetable anatomy and physiology successively at Amsterdam and at Wurzburg, continued the researches of the Abbé Mendel (q.v.), and wrote on botanical physiology.

**De Vries, MATTHIAS** (1820–92), Dutch lexicographer and philologist, wrote on Middle Low German and Old Dutch.

**Dew.** The question of the origin of dew has been discussed since very early times, and many theories have been advanced on the subject. Among more recent writers, Gersten, followed by Du Fay, held that dew rose from the ground. Others believed that it fell from above, but no really systematic treatment of the subject appeared until the publication of Wells's *Essay on Dew* in 1814. Wells combated the opinion of Du Fay and Gersten, and showed that all the phenomena described by them could be equally well explained by his theory. He asserted that the dew was condensed out of the air in contact with surfaces below a certain temperature. For every definite pressure and temperature of the atmosphere there is a definite amount of water-vapour per unit-volume which can be held in suspension. Hence, when air containing a certain amount of water-vapour is cooled below a particular temperature, the vapour is condensed. This temperature is called the *dew-point* of the atmosphere under the given conditions as to pressure and quantity of vapour. At night the earth and objects at its surface are being cooled by radiation. If the rate of loss of heat by radiation is sufficiently rapid, the temperature of the earth's surface, and consequently of the air in immediate contact with it, may fall below the dew-point. When this occurs, the moisture condenses on the surface in the form of dew. This is Dr Wells's theory regarding the formation of dew. He considered that the vapour had risen from the ground during the previous day, and that very little dew was formed from vapour which had just risen from the ground, although he admitted that some might be so produced.

Wells's theory of the *formation* of dew is undoubtedly correct, but, in a paper read in 1885 before the Royal Society of Edinburgh, Dr John Aitken adduced evidence which shows that the *greater part* of dew is formed from vapour which has *just* risen from the ground and been trapped by the grass and other objects. Dr Aitken was led to

this conclusion by three independent experimental methods. One of these consists in removing at sunset a portion of turf from the ground, placing it in a shallow metal pan and weighing it. The turf, still contained in the pan, is then replaced in the ground in good heat-communication with it. When reweighed after some time, it is invariably found to have lost weight. If the turf be covered by a metal tray so as to prevent escape of moisture, this loss of weight is largely obviated. Similarly, it is shown that moisture rises always during the night from bare soil, from roads, and from the driest earth.

Certain atmospheric conditions are necessary for the copious formation of dew. The sky must be clear, otherwise the clouds will radiate back much of the heat given off from the earth, and so will prevent the surface objects from cooling below the dew-point. The atmosphere must be calm, or the air next the ground will be carried away before it is completely saturated. Below the freezing-point, the dew is deposited in a solid state as *hoar-frost*. See EVAPORATION, METEOROLOGY.

**Dewar, SIR JAMES** (1842–1923), physicist and chemist, was born at Kincardine on Forth, and educated at Dollar Academy and the universities of Edinburgh and Ghent. From 1875 to his death, 27th March 1923, he was Jacksonian professor of natural philosophy at Cambridge; and from 1877 he was also Fullerman professor of chemistry at the Royal Institution, London. His researches covered a wide field, but best known to the public are his achievements in the liquefaction and freezing of gases and other work with low temperatures, out of which sprang his invention of the vacuum or 'thermos' flask.

**Dewas**, two native states of Central India, with a total population of 137,000.

**Dewberry** (*Rubus cæsius*) is distinguished from the Common Bramble (of which, indeed, many regard it as a mere sub-species) by its weaker and more prostrate glaucous stem, with scattered pickles, but without bristles or glandular hairs, also by the few large drupes, which make up its fruit, and which have a characteristic dew-like bloom, whence the name arises. The fruit is very sweet and agreeable, and makes an excellent wine. The dewberry of North America (*R. procumbens*), abundant in the forests of Canada, is a delicious fruit, much superior to the British fruit of the same name, and more tart. The plant is of very humble growth, scarcely rising above the ground.

**D'Ewes, SIR SIMONDS**, antiquary, was born 18th December 1602 at Coxden, near Chard, and in 1618 entered St John's College, Cambridge. In 1623 he was called to the bar, but in 1626 he married a rich child-heiress, and was knighted. He attended the Long Parliament as member for Sudbury. A Puritan, but a moderate, he accepted a baronetcy (1641), sided with the parliament, was expelled by Pride (1648), and died 8th April 1650. His diaries and transcripts of manuscripts which else had perished possess high value; W. Notestein edited his *Journal* (1924).

**De Wet, CHRISTIAN**, born at Viedepoort, Orange Free State, in 1854, had acquired fame as a hunter ere he became conspicuous in the Transvaal war of 1880–81; and in the war of 1899–1902 he was of all the Boer commanders the most audacious, swift in movement, and fertile in expedients, especially in escaping being cornered. After the submission he came to Europe to raise money for the distressed Boer families, and was Orange River Colony Minister of Agriculture in 1907–10. He joined the South African rising of October 1914, was taken prisoner in December, fined and sentenced to six years' imprisonment, but released in December 1915. He died 3d February 1922.

**De Wette**, **WILHELM MARTIN LEBERECHE**, biblical critic, was born at Ulla, near Weimar, on the 12th January 1780. He studied from 1799 at Jena under Griesbach and Paulus, and early attached himself to the philosophy of Fries. He became extraordinary professor of Exegesis at Heidelberg in 1807, and ordinary professor in 1809, and in 1810 was called to the newly-founded university of Berlin. For a letter which he had sent on the 31st March 1819 to his friend, the mother of Sand, the assassin of Kotzebue, he was deprived of his professorship; and retiring to his native place, he completed his *Christliche Sittenlehre* (3 vols. 1819-21), his edition of the *Briefe, Sendschreiben und Bedenken Luthers* (5 vols. 1825-28), and the religious novel *Theodor, oder des Zweiflers Weihe* (1822; Eng. trans. 1849). A call to be preacher at Brunswick was vetoed by the government, and in 1822 he was appointed professor of Theology at Basel, where, in 1829, he was honoured with a seat in the Council of Education, and died 16th June 1849. His great reputation as a biblical scholar rests on his *Beiträge zur Einleitung in das Alte Testament* (2 vols. 1806-7), his *Lehrbuch der hebraisch-jüdischen Archäologie* (1814; 4th ed. 1864), and especially his very useful *Lehrbuch der historisch-kritischen Einleitung in die Bibel* (1817-26), which ran to many editions. His translation of the Scriptures, undertaken in conjunction with Augusti (6 vols. 1809-12); *Commentar über die Psalmen* (1829); and *Kurzfassendes exegetisches Handbuch zum Neuen Testament* (3 vols. 1836-48), were extensively used by students. 'He possesses soul enough,' says Tholuck, 'to distinguish between the spiritual kernel and its husk in the language of the Bible; interest, besides, in its ideas and doctrines; and, finally, a sound exegetical tact, equally removed from exegetical coxcombry and from arbitrariness and inexactitude.' His works on dogmatic theology, *Ueber die Religion* (1827), and *Das Wesen des christlichen Glaubens* (1846), are of less importance.

See the estimates of De Wette's merits by Schenkel (1849), Lücke (1850), Hagenbach (1850), Wiegand (1879), and Stähelin (1880).

**Dewey**, **GEORGE** (1837-1917), American admiral, born at Montpelier, Vermont, served in the civil war, and as commodore in 1898 destroyed or took the whole Spanish fleet at Manila Bay without losing a man.

**De Wint**, **PETER**. See **WINT**.

**De Witt**, **JAN**, a celebrated statesman of Holland, born at Dort in 1625, was the son of Jacob de Witt, a vehement opponent of William II. Prince of Orange. Jan inherited his father's hatred of the office of stadhouder, and of the family that filled it. His education was carefully attended to, and he soon exhibited remarkable ability. He was one of the deputies sent by the States of Holland in 1652 to Zeeland for the purpose of dissuading that province from adopting an Orange policy, and there his eloquence secured him universal confidence. In the following year he was made grand pensionary. The Orange party (supported by the populace and the clergy), during the war carried on between England and Holland, was ever striving to increase the power of the young prince (afterwards William III.), who was then a mere infant; the republican, or oligarchic party, composed of the nobles and the wealthier burgesses, at the head of which was De Witt, on the other hand sought to strip the House of Orange of all power, and to abolish entirely the office of stadhouder. During William's minority the advantage was, of course, with De Witt and the republicans. In 1654, on the conclusion of the war with England, a secret article was inserted in the treaty drawn up

between De Witt and Cromwell, in virtue of which the House of Orange was to be deprived of all state-offices. After the restoration of Charles II., De Witt leaned more to the side of France, all the more when hostilities were renewed between England and Holland in 1665. During the two years' war De Witt's influence declined, but his star paled altogether when the designs of Louis XIV. upon the Spanish Netherlands became manifest. The Orange party carried their point in the elevation of William to the family dignity of stadhouder and commander of the Dutch forces, but the first campaign proved unfortunate. De Witt had resigned his office of grand pensionary. His brother, Cornelis, accused of conspiring against the life of the stadhouder, was imprisoned and tortured. When Jan went to meet his brother on his release they were attacked by an infuriated crowd, and were both torn to pieces (20th August 1672).

De Witt left memoirs and letters, published 1709 and 1725. See Lives of him by Simons (1836), Knottenbelt, Geddes, and Pontalis (trans. 1885).

**Dew-ponds** are water-holding hollows in the waterless Sussex downs and elsewhere, depending for their supply on the depositions from dew or mist on cool summer nights. Some ancient British camps seem to have relied on them. The presence at the edge of a tree or two is thought to be helpful in condensing the moisture. See *Nature* for April 1905, page 61; A. J. and G. Hubbard, *Neolithic Dew-Ponds and Cattle-Ways* (new ed. 1916).

**Dewsbury**, a manufacturing town and county and parliamentary borough in the West Riding of Yorkshire, situated at the base of a hill, on the left bank of the Calder, 32 miles SW. of York, and 8 miles SSW. of Leeds. The Calder navigation connects the town with Liverpool and Hull. Dewsbury has a chamber of commerce formed in 1861, an infirmary (1883), a town-hall (1888), county courts, and a grammar-school (St Augustine's). Along with Batley (q.v.) it is the centre of the shoddy trade. Blankets, carpets, and yarns are largely manufactured. There are also foundries, as well as a number of minor industries. Dewsbury obtained a municipal charter in 1872. Pop. (1861) 18,148; (1881) 29,639; (1901) 28,060; (1911, after absorbing Thornhill, &c.) 53,351; (1921) 54,163. The (one-member) parliamentary borough (1867) included Batley and Soothill till 1918, when it was made continuous with the county borough.

**Dexter**, in Heraldry, that side of a shield or armorial figure or composition which is to the left, not the right, of the spectator. This nomenclature is adopted because it covers the right side of the warrior who carries the shield.

**Dextrine** ('British gum,' 'torrefied starch'). When starch is carefully heated to 392° F. (200° C.), or until vapours arise from it, it becomes soluble in cold and hot water, and loses its gelatinous character; it also has the property, when viewed by polarised light, of turning the plane of polarisation to the right; hence its name. It is often used as a substitute for gum-arabic in the processes of calico-printing, and for stiffening different goods; it is also applied to the back of postage-stamps. Its value as a substitute for gum consists in its being more flexible and less brittle when dry than that substance. Starch may be converted into dextrine by the long-continued action of dilute acids at a high temperature; also by the action of Diastase (q.v.). Dextrine and starch are isomeric, both being composed of  $C_6H_{10}O_5$ ; but dextrine may be distinguished from the latter body by its not being rendered blue by iodine, which gives with it a dingy purple tint.

**Dextrose**. See **SUGAR**.

**Dey** (Turkish *dai*, 'a maternal uncle'), a name applied to the governor of Algiers before its conquest by the French. The name was formerly given to elderly people, especially among the Janizaries; hence came to be commonly applied at Algiers to the commanding-officer of that corps, who frequently became afterwards pasha or regent of that province. See **BEG**.

**Dhar**, a town of Central India, lying at an elevation of 1908 feet above the sea, 33 miles W. of Mhow. It has over 17,000 inhabitants, and preserves, in two large mosques of red stone and a fort defended by a high rampart and twenty-six towers, traces of bygone magnificence. It is the capital of a protected state of the same name, with an area of 1783 sq. m., and 154,000 inhabitants.

**Dharmasala**, a hill-station in the Punjab, 110 miles N.E. of Lahore; pop. 7000.

**Dharwar**, a town and district in the southern Mahratta country, in Bombay Presidency, separated by the river Tungabhadra from Madras. The town has no manufactures of importance, but a good deal of trade. Pop. 30,000.—The district has an area of 4600 sq. m., and a pop. of 1,000,000, mostly Hindus. The most interesting feature of the country is its suitability for the growth of American cotton, which now occupies a third of the total acreage devoted to cotton. Cotton and silk cloth are manufactured in the district. The prevalent language is Canarese.

**Dhole**, the wild dog of India. See **DOG**.

**Dholka**, a town of India, in Bombay Presidency, 22 miles SW. of Ahmadabad, with a reputation for the weaving of women's robes. It is surrounded by a mud wall 4 miles in circuit, and lies amid the ruins of noble palaces and tanks, many dating from the early Hindu period. Pop. 13,700.

**Dholpore**, a native state of Rajputana, in Central India, on the northern bank of the Chumbul, with an area of 1155 sq. m., and a pop. of 263,000, mostly Hindus. Capital, Dholpore, on the Chumbul, 34 miles S. of Agra by rail. A large fifteen days' fair is held here in October, and two religious fairs are held every year at Machkund, a lake 3 miles to the west, with numerous temples on its banks. Pop. 20,000.

**Dhuleep Singh**. See **SIKHS**.

**Dhunchee**, or **DHANCHI** (*Sesbania aculeata*), an annual herbaceous leguminous plant cultivated in Bengal on account of its coarse hemp-like fibre. It is steeped and prepared very much like Sunn (q.v.). Other species are of similar use.

**Dhwalagiri** (*Divalagiri*), once supposed to be the highest peak of the Himalayas, but now ascertained to be exceeded by several in point of altitude, has a height of 26,826 feet above the sea. It is in Nepal.

**Diabase**. See **BASALT**.

**Diabetes** (Gr., lit. 'a syphon,' from *diabainō*, 'I go or flow through'), a disorder of the general system, of which the principal symptom is a greatly increased flow of urine. Diabetes is of two distinct kinds: the one, *diabetes insipidus*, is a mere exaggeration of the water-excreting function of the kidneys, accompanied by extreme thirst, and hence called *polydipsia* (Gr., 'excess of thirst') by some authorities; the other is a more complex disorder of the assimilation, consequent on the formation first, and the excretion by the kidneys afterwards, of an enormous excess of animal sugar or glucose (see **SUGAR**), the sugar being found in excess not only in the renal excretion, but in the blood, and in nearly all the secretions which have been examined. The pathology of this disease, called *diabetes mellitus* (Lat. *mel*, 'honey'), is very obscure, notwithstanding the numerous recent

physiological researches, especially those on the liver, pancreas, and ductless glands, but defective secretion of insulin by the pancreas plays a large part in its origin. Along with wasting of the body, due to the discharge of sugar, there is a tendency to poisoning of the system from the presence in the blood of acid substances, acetone, &c., some of which can also be discovered in the urine. This condition is known as acidosis. The course of the disease is very different at different periods of life. Before middle age it is severe, progressive, and very liable to be fatal. After that period precisely similar symptoms often appear, especially in stout and gouty persons, but are much less dangerous, and much more easily controlled. All diabetics are subject to progressive emaciation, and they often become subject to skin diseases like eczema and boils, and to consumption.

The first fact observed in cases of diabetes is usually the increased flow of urine, when it becomes so great as to amount to a practical inconvenience; and also a considerable increase of the appetite, and an unquenchable thirst, which rarely fail to accompany the disease from the beginning, but often do not attract attention, or at least suggest the idea of anything wrong, till an advanced stage of the disorder. When the patient demands medical assistance he is usually somewhat thin; the pulse is quiet, the skin cool, the heat of the surface, indeed, habitually rather low and easily depressed. There is often a complete absence of perspiration, which gives a peculiar feeling of harshness to the surface, especially of the palms of the hands. Owing to the withdrawal of fluid from the bowels constipation is often a troublesome symptom. With these symptoms the first approaches of pulmonary disease may concur. In the very last stages there is sometimes dropsy of the feet; and the urine may be natural in quantity, or even diminished. For the other characters of diabetic urine, see **URINE**. Diabetic persons bear excitement and fatigue, either mental or bodily, extremely badly; and imprudence in this respect is not unfrequently followed by sudden or rapid collapse and death.

Treatment consists mainly in removing from the diet, as far as consistent with comfort and due nourishment, everything which easily turns to the formation of glucose in the system, and at the same time in preventing the onset of acidosis. The complete suppression of sugar-forming food, however, as recommended long ago by Rollo, has not been found possible, nor is it desirable, since acidosis is more apt to develop on a completely sugar-free diet. Bread composed of gluten of wheat without starch, or bran-cakes baked with eggs, or biscuits made of almonds, have been strongly recommended; and in most of the great capitals, as London and Paris, bakers may be found who regularly furnish bread suitable for diabetics. An oatmeal diet, consisting of a daily allowance of half a pound of oatmeal made into gruel with three ounces of butter and white of eggs, has been strongly recommended. The starvation method of treatment consists in withdrawing all food for one, two, three or more days till the urine becomes free from sugar, then putting the patient on a strict sugar-free diet to which farinaceous and other foods are gradually added till the amount that the patient's system can assimilate without producing sugar is discovered. This amount of farinaceous and sugary material is then allowed in the regular diet. Saccharin (q.v.) has lately been of great service to diabetics, as it supplies the flavour of sugar without its objectionable properties. There is no specific medicine, and the unguarded use of strong remedies is to be condemned. Careful dieting is the main feature in treatment, and the

recent discovery of insulin, a substance extracted from the pancreas of oxen and other animals, has proved of great help. Injected beneath the skin before meals it checks waste of sugar, and is of especial use in the severest cases. The action of the skin should be aided by warm clothing and frequent hot baths, and the bowels must be carefully regulated.

**Diablerets**, a remarkable mountain of the Bernese Alps, Switzerland, on the frontier of Bern and Valais, with a height of 10,651 feet above the sea. The Diablerets, with their four main peaks, are composed of limestone strata, the lower beds of which are so soft and shaly that they are easily disintegrated, and masses falling down into the valley from above cause the most terrible catastrophes, as in 1714 and 1749.

**Diacoustic.** See CAUSTICS.

**Diachylon.** See PLASTERS.

**Diadochi.** See GREECE.

**Diæresis** (Gr., from *diæreō*, 'I divide'), a term used in Grammar to signify the resolution of a diphthong, or of a contracted syllable, into two syllables; as Lat. *auræ* into *aura*. The name is also given to the mark  $\cdot$  placed above a vowel letter to indicate that it is to be independently pronounced, and not in conjunction with a preceding vowel; as in the above example, or in the word *aerial*. See UMLAUT.

**Diagnosis** (Gr., from *dia*, 'through,' and *gnōsis*, 'knowledge'), in Medicine, the discrimination of diseases. It includes the study of all the vital phenomena of diseases, and also of their appearances after death, in so far as this can aid their discovery during the life of the patient. It is usual to speak of rational or physiological diagnosis, or diagnosis by symptoms—i.e. changes chiefly functional, observed by the patient; and of physical diagnosis, or diagnosis by signs—i.e. objective phenomena appreciable by the senses of the observer. The latter method of diagnosis has been much enlarged in scope and increased in importance by the modern methods in medicine of Auscultation (q.v.) and Percussion (q.v.), and also by the great advances made in physiological chemistry, and by the use of the microscope. Skill in diagnosis is one of the highest gifts of the physician, and nothing distinguishes the man of long experience from the tyro more than this unerring insight into some unseen disease. See STETHOSCOPE, LARYNX, OPHTHALMOSCOPE, &c.

**Diagonal Scale.** See SCALES (MATHEMATICAL).

**Diagoras** (surnamed the 'atheist'), a Greek poet and philosopher, was born in Melos, an island of the Cyclades. He is said to have been a disciple of Democritus of Abdera, and he is alluded to by Aristophanes in the *Clouds* (424 B.C.). He seems to have been witty and fearless, and probably treated the superstitions of the popular religion with contempt. He was formally accused of impiety in 411, and only saved his life by flight to Pallene, and afterwards to Corinth, where he died. He wrote lyrics and a philosophical work, none of which have been preserved.

**Dial and Dialling.** A *sun-dial* is an instrument for measuring time by means of the motion of the sun's shadow cast by a stile erected on its surface. It is an instrument of very great antiquity, and before clocks and watches became common, it was in general use as a time-keeper. Some old sun-dials are very elaborate—e.g. that at Glamis Castle, Fife-shire; and many bear quaint mottoes (cf. *Leisure Hour*, 1870, p. 413; and Mrs Gatty's *Book of Sun-Dials*, 4th ed. 1900). Dial-making was

then an important branch of mathematical study; now it is more an object of curiosity than utility. A dial consists of two parts—the *style* or gnomon, usually the edge of a plate of metal, always made parallel to the earth's axis, and pointing towards the north pole; and the *dial-plane*, which may be of any hard substance, and on which are marked the directions of the shadow for the several hours of the day, their halves, quarters, &c. Dials receive various names, according mostly to the positions which they are constructed to occupy. When the dial-plane is on the plane of the horizon, the dial is called a horizontal dial; when perpendicular to that plane, a vertical dial. An equinoctial dial is one whose plane is parallel to the equinoctial plane. The south dial, north dial, east dial, west dial, polar dial, declining dial, are named from the position of the dial-plane. The cylindrical dial is a dial drawn on the curved surface of a cylinder. The ring dial is an ingenious small portable dial, but rather a curious toy than a philosophical instrument. A *night* or *nocturnal dial* is an instrument for showing the hour of the night by the shadow of the moon or stars. Moon-dials may be constructed relative to the moon's motion; or the hour may be found by the moon's shadow on a sun-dial. But because of the irregularity of the moon's motion, due to its varying speed at different parts of its orbit, the time so found is subject to considerable error.

**Dialling.**—The *style* of a dial being parallel to the earth's axis, those familiar with spherical trigonometry will readily see that the problem of constructing a dial resolves itself into that of ascertaining where the hour-lines cut a given circle, with a view to the graduation of the dial-plane. Suppose *Pep* (fig. 1), a hollow and transparent sphere, as of glass, to represent the earth; and suppose its equator divided into 24 equal parts by the meridians *a, b, c, d, &c.*, one of them passing through a given place, say London (see HORIZON), at the point *a*. If the hour of twelve be marked at the equator, both on the latter meridian and that opposite it, and all the rest of the hours in order on

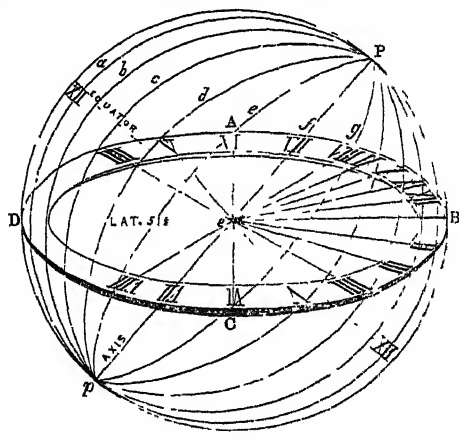

Fig. 1.

the other meridians, those meridians will be the hour-circles of London, because, as the sun appears to move round the earth in 24 hours, he will pass from one meridian to another in one hour. Then, if the sphere has an opaque axis, as *Pep*, terminating in the poles *P* and *p*, the shadow of this axis would fall, in the course of the day, on every particular meridian and hour, as the sun came to the plane of the opposite meridian, and would thus show the time at London, and at all other places

on the same meridian as London. If the sphere were cut through the middle by a plane ABCD, in the rational horizon of London, and if straight lines were drawn from the centre, E, of the plane to the points where its circumference is cut by the hour-circles of the sphere, those lines would be the hour-lines of a horizontal dial for London; for the shadow of the axis would fall upon each particular hour-line of the dial, when it fell upon the like hour-circle of the sphere. Similarly, if we suppose the sphere cut by *any* other plane facing the meridian, the hour-circles of the sphere will cut the edge of the plane in those points to which the hour-lines must be drawn straight from the centre; and the axis of the sphere will cast a shadow on these lines at the respective hours. The like will hold of any plane, whether it face the meridian or not, provided it do not coincide with it, or do not coincide with a plane through the poles, and perpendicular to the plane of the equator. In the latter case, the axis would have no elevation above the plane of the dial; in the former, the shadow would not move circularly.

The *universal dialling cylinder*, an invention of Ferguson's, is represented in fig. 2. ABCD is a

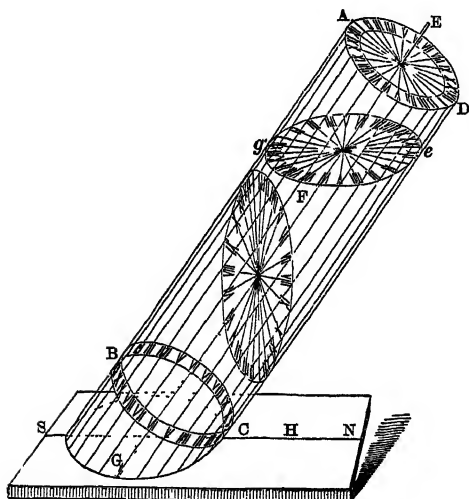

Fig. 2.

glass cylindrical tube, closed at both ends with brass plates, on the centres of which a wire or axis, EFG, is fixed. The tube is either fixed to a horizontal board, H, at an angle equal to the latitude of the place, or moves on a joint, so that it may be elevated till its axis is parallel to the earth's at any latitude. The 24 hour-lines are drawn on the outside of the glass, equidistant from one another, and parallel to the axis. The XII next B stands for midnight; the XII next B stands for noon. When the axis is adjusted for the latitude, and the board levelled, with the line HN on the meridian, and the end towards the north, the axis EFG, when the sun shines, will serve as style, and cast a shadow on the hour of the day among the parallel hour-lines. As the plate AD is parallel to the equator, and EFG perpendicular to it, right lines drawn from the centre to the extremities of the parallels will be the hour-lines of an equinoctial dial, and the axis will be the style. A horizontal plate, *ge*, if put into the tube, with lines drawn from the centre to the several parallels cutting its edge, will be a horizontal dial for the given latitude; and similarly a vertical plate fronting the meridian, and touching the tube with its edge, with

lines drawn from its centre to the parallels, will be a vertical south dial, the axis of the instrument in both cases serving for the stile; and similarly for any other plate placed in the cylinder. If, instead of being of glass, the cylinder were of wood, any of these dials might be obtained from it by simply cutting it in the planes of the plates, and drawing the lines on the surface of the section.

Dialling sometimes occurs as a term for surveying by help of a compass with sights, such as is called a 'miner's dial,' and is used especially in underground surveys.

**Dialects.** The word dialect is rather loosely applied in popular usage to certain local or provincial forms of speech which exist in all countries, side by side with the more important form which is known as the standard language. The latter type of speech is considered as the *Language* proper, and the other, less widely-spread forms are often conceived to be mere offshoots and 'corruptions' of it. So far as the genuine provincial dialects are concerned, this view cannot be supported.

Among students of philology the term *dialect* is generally applied to all closely related varieties of speech, whether these be confined severally to small and obscure communities of peasants, or current among larger groups of population, such as great industrial communities; whether they be the linguistic instruments of highly educated circles, of the most cultivated and refined classes, or whether they pass muster only among the rougher, less instructed, and less distinguished sections of the nation. It is immaterial to the conception of a dialect in this special sense, whether the form of speech so designated is or is not commonly used in writing, or whether it is the vehicle of a literature or not.

There is no essential difference between dialects and languages; both exist as means of social intercourse between members of certain communities, large or small; that is, both are forms of human speech, and are modified by the changing habits of those who speak them. But while this essential identity of character must be borne in mind, it is often useful to apply the term *language* to those forms of speech which acquire importance and prestige by having a wide currency, not only over a large area, but also among all sections of a nation—so that a national language may be used alongside of other, purely local, varieties—a form of speech which is the recognised medium of official, diplomatic, and commercial communication throughout a country, which is the traditional vehicle of a people's culture and of its main literary productions. Such a form of speech, the national language of a great community, is, and can only be, in its origin, one among many varieties, or dialects, which, owing to geographical, social, and political conditions, has gradually attained a degree of importance above other dialects and risen to the dignity of a standard language.

Every civilised country, whose people possess an ancient culture, some degree of unity based upon political constitution, or upon religion, and a national literature, evolves in time, from among its forms of speech, often highly differentiated, one central language which is usually at once the medium of government and the more refined types of its social life, and the means of expression for its best thought and its literature.

The problem which concerns us immediately is how do varieties first arise in a language which, as we must assume that of primitive communities to be, was originally homogeneous?

The conditions which make for unity of speech are those under which the unity of a community is preserved; that is, conditions under which the

greatest possible facilities exist for frequent and intimate social intercourse between all the members of a community. This intensity of social intercourse is chiefly possible when a community is small, when the members live together in a comparatively restricted area, and when there is the minimum of diversity in occupation, and in standing between them. The existence of a system of highly developed occupational specialisation, tending to give rise to different castes or classes, would impair the unity of social intercourse. Another disturbing factor is the scattering of a community over a wide area, in conditions under which the various families dwell some distance apart from each other, and tend, with their households and dependents, to form, in time, so many separate hamlets, or villages.

So long as social unity and actual contiguity of individuals and families are maintained, the dialect of such a community will remain uniform and homogeneous among all the members. There will be, it is true, changes of various kinds which will continue from generation to generation, but such changes will affect equally the speech of every member of the community. The speech of all will change in course of time, but that of each individual will change in the same way. Thus, in spite of natural development, the dialect remains one and homogeneous. The reason for this is that under the conditions described, those tendencies to change which exist among a minority of the speakers only are eliminated. Those tendencies, on the other hand, which exist among all the members of the community are fostered and encouraged. It is the social linguistic intercourse which, without the speakers being aware of it, eliminates the one and fosters the other set of tendencies.

The essential condition for the differentiation of a uniform dialect, and the rise of varieties of speech, is the existence of some factors which disturb the social unity and break up the community into several separate groups or sections. When once this happens, when what was formerly a single community is split into several, the process of linguistic differentiation is inevitable. Each of the new social groups develops its language on lines more or less different from the others, and we have the beginnings of new dialects. The reason for this is that among the new and smaller communities there will be a distribution of linguistic forces and tendencies different from that which prevailed in the original community. The old balance of tendencies of elimination and of preservation is upset. Variations in speech existing among a minority of individual speakers which formerly were suppressed, owing to the unconscious pressure of the general trend of development in the community as a whole, under the new conditions gain ground, find a larger public with whose tendencies they agree, and finally become established as characteristics of this or that new dialect. On the other hand, tendencies which before existed among a majority of the speakers under the old conditions, and were therefore preserved, may now exist among only a small proportion of speakers, and will therefore be suppressed. In each of the new communities a different set of individual tendencies gets the upper hand, and each will differ to a greater or less extent from those which prevailed before the breaking up of the old community took place.

It may be said, then, that dialects arise from the segregation of speakers into groups, and the isolation of these groups from each other. The factors which produce the separation or isolation of group from group may be classed under two heads—geographical factors and social factors.

The former class includes geographical and physical factors of separation generally, the natural features of the country—mountain-ranges, rivers, forests, tracts of desert or tundra. The second group includes whatever barriers to social intercourse and linguistic contact arise from the structure of society—differences of occupation, caste, and class. It is convenient to distinguish varieties in speech, caused severally by these two kinds of factors, as REGIONAL, and CLASS or SOCIAL dialects respectively. The former arise in a primitive condition of society, when, under stress of hunger, large portions of a community wander off to remote areas in search of food for themselves and pasture for their cattle. Migration is clearly a potent means of isolation, and the geographical barriers placed between communities as a result of this, form the completest possible separation between the speakers who compose the various tribes. Moreover, migration may bring about a complete change in the mode of life, difference of climate, food, and social structure, and, further, it may bring the nomads into relation with other tribes possessing a different civilisation, and speaking an entirely different language. All these things, which are incidental to geographical separation, bring in their train so many additional causes of linguistic differentiation. Climate was formerly held to be a powerful factor in determining the character of a language. It cannot be denied that climatic conditions operating over a considerable period must exercise considerable influence upon the physical and mental constitution of speakers, and that these must, in some way, react upon their language. At the same time, it appears at present impossible to say in what precise way language is affected by climate; we have not yet been able to show that this or that feature in a given language is the result of this or that climatic condition. The influence exerted reciprocally by races speaking different languages is more easily understood. No considerable influence of one language upon another is possible without prolonged social contact between the races. When this happens, there is first a period of bilingualism, and then usually the gradual disappearance of one of the languages. The surviving language, which may, according to circumstances, be that either of the conquerors or new-comers, or that of the original inhabitants of the area, cannot fail to be more or less modified by the other before it disappears, in vocabulary, pronunciation, and possibly also in grammatical structure. It must be borne in mind, that unless one of the races is practically exterminated by the other, a thing which perhaps rarely happens, the community is of mixed race, which means that a portion of it has adopted a form of speech which was once foreign to it. A foreign tongue thus acquired is variously altered by those who adopt it. Not only so, but it is started on lines of development to some extent different from those it followed before. The new, mixed community will possess fresh tendencies of change.

Some attribute the remarkable differentiation exhibited by the various branches of Aryan speech, in a large measure, to the influence of non-Aryan speakers. The effects of geographical isolation, and all that this entails, are seen not only in the various character of the principal branches of the Aryan language, but in the high degree of differentiation existing within the individual branches of this family. The Hellenic dialects arose under conditions of geographical dispersion which were ideally favourable to linguistic differentiation, and the same may be said of the innumerable Romance dialects which arose in the widely separated provinces of the far-flung Roman empire. Again, we may point to English, a branch of West Germanic, which has pursued very different lines of develop-

ment from its nearest speech-cousins on the Continent, as a result of centuries of complete geographical isolation from the main body of West Germanic speech.

We now pass to the social factors of isolation, the barriers set up by occupation, caste, or class. These arise in every community so soon as this attains to any complexity of structure. The factors of occupation and class are by no means so thorough in their action as the geographical factors; they do not involve a separation in distance of the various sections of society. On the other hand, social conditions undoubtedly do split a community up into various groups, which, while they often dwell side by side, and admit of much social intercourse between them, are nevertheless isolated from one another in many ways—by more or less different conditions of life, different preoccupations and interests, differences of education, different standards of taste, by the many circumstances which arise out of class distinction. Among these various social groups there exist varieties of dialect, different in degree, and often in kind, from those which obtain between different regional dialects.

An inevitable result of this differentiation is the rise of a standard language, that is, the dialect of a particular region, and a special variety of it spoken by a definite group of speakers, usually the upper class, and especially of an official class of courtiers and governing persons. The standard gradually dispossesses the regional dialects in most areas among the upper and educated classes. But it soon passes beyond the limits of a single class, and is acquired by many others—by all speakers, in fact, who have given up their old regional dialects. Now begins a fresh process of differentiation. By the side of standard type, a number of varieties developed from it spring up among different classes, and in different areas. These modifications of the standard are in part purely the result of social factors, but the existing regional dialects may also play a part in the process.

The modified forms of the standard may become definitely fixed and traditional, and undergo, independently of the standard, characteristic changes of their own. They are, in fact, separate dialects, each with its own tendencies to change. In course of time these new class dialects may react upon the standard itself, and in English, for instance, there is no doubt that for several centuries the spoken form of the standard language, and, through this, the written form also, has been greatly affected by the other class dialects. (See ENGLISH LANGUAGE)

The class dialects, which differ widely from the standard of a given age, are considered by speakers of this as VULGARISMS; features derived from the regional dialects, which are frankly popular forms of speech, when introduced into a form of speech which aims at being the standard, are called PROVINCIALISMS. The importance and interest of class dialects, both as illustrating a particular kind of speech differentiation, and on account of their influence upon the standard spoken and written language, are now recognised by philological students. The study of regional dialects, both in their oldest recorded forms and in their latest living developments, has long been pursued by philologists. In many European countries, notably in France, Scandinavia, and Germany, much learning and ability has been devoted to their investigation.

The special reasons for the study of living popular dialects are the following:

(1) Popular speech is, on the whole, free from arbitrary rules imposed by convention, in the interests of a supposed correctness. They therefore offer a better field than the more polished type of

speech in vogue in polite society, and in literature, for the observation of the actual processes of development which tend, in all ages, to affect human speech.

(2) Popular dialects often preserve old features of all kinds which have been lost in the standard language. They therefore often help to explain forms which occur in the standard itself in its earlier phases.

(3) Since the standard language of most countries is, in origin, rarely a completely pure regional dialect, but rather a combination which has grown up in an area where several regional types of speech are in contact, the study of living dialects often throws light upon the original sources of the standard.

(4) Apart from those types which were naturally mingled by actual juxtaposition in certain areas, a standard language may, at various periods, incorporate isolated forms from more or less remote regional types of speech. These forms appear in the standard as 'exceptional,' and seem at first sight to be out of harmony with the general trend of development. Their origin may often become clear from the study of living regional dialects, in which they are found to be normal. It is not always possible to explain how such isolated features have passed into the standard. The channel through which they have passed is in most cases a class dialect tinged with provincialism. See ENGLISH LANGUAGE (*Dialects*); GREEK (*Language*), &c.

Forschungen*, vol. iv. pp. 36-45; Wechsler, *Gibt es Lautgesetze?* H. C. Wyld, *Hist. Study of Mother Tongue*, chap. v., 'Differentiation of Language.'

**Dialectic** is a Greek word which signified originally 'the art of rational conversation,' but came to have a technical signification in the language of philosophy. At first it implied a regular and scientific method of treating general conceptions or general terms—a sort of anatomy of names, and through them of the things denoted. In the Socratic philosophy, and more especially in that of Plato, dialectic was thus the method of the highest and deepest kind of speculation. Aristotle gave another signification to the word. According to him, a scientific proof or deduction is different from a dialectic proof, which is only a probable deduction. After this, dialectic came round to imply a kind of fencing in words, the art of so using the forms of reasoning as to confound your opponent, and make fallacies pass for truth. Dialectic is sometimes used as synonymous with logic. The Hegelian philosophy regards dialectic as at once the method of knowledge and of the evolution of the universe itself.

**Diallage** (Gr. *diallage*, 'interchange;' so called from its changeable colour), a mineral nearly allied to Augite (q.v.), and by some regarded as a variety of it. Its chemical composition is essentially the same. It is seldom found perfectly crystallised, but usually massive, granular, or disseminated, and is characterised by its markedly laminated structure. It is brown, gray, or green in colour, but shows a kind of metallic lustre when broken across the cleavage. This is due to the presence of microscopic tubular inclusions or leaflets, which are disposed parallel to the cleavage-planes or laminae. Diallage is a rock-forming mineral of some importance, occurring as a primary constituent of normal Gabbro (q.v.).

**Dialogue**, a conversation between two or more persons, implying, however, greater unity and continuity of subject than an ordinary conversation. The ancient Greek philosophers were fond of this

way of conducting their investigations and conveying their instructions. The Socratic dialogue is a conversation in the form of question and answer, so contrived that the person questioned is led himself to originate those ideas that the questioner wishes to bring before him. The dialogues of Plato are, as it were, philosophical dramas, in which the Socratic method of investigation is brought to bear upon speculative subjects. One of the greatest masters in this form was Lucian, whose keen-edged and brilliant wit was especially adapted to it. The dialogue is but ill adapted to the exposition of modern science, although elementary hand-books in the form of question and answer are still useful as supplying the student with a series of concrete facts tersely expressed. Of the more eminent modern writers of the literary forms of dialogue, we may mention Erasmus in Latin; Lessing, Herder, and Wieland among the Germans; Petrarch and Machiavelli in Italy; Fénelon, Fontenelle, and Diderot in France; and in England, Berkeley, Swift, Hurd, Harris, Helps, and Landor in his *Imaginary Conversations*. Dialogue combined with action gives us the drama.

**Dialysis.** See OSMOSE, DIFFUSION.

**Diamagnetism.** Bodies such as iron, when placed in a field of magnetic force, tend to move from places of weaker to places of stronger force. The opposite is true of bismuth and other substances. Such substances are said to be *diamagnetic*. For further information, see MAGNETISM.

**Diamantina**, an episcopal town, of mean appearance, in the Brazilian province of Minas Geiaes. It is the centre of a rich diamond district, and has manufactures of cotton and goldware. Pop. 13,000.

**Diameter**, in Plane Geometry, is generally a straight line bisecting any system of parallel chords of a conic section. The lines which it bisects are termed its *ordinates*. In the circle, ellipse, and hyperbola, every diameter passes through the centre of the curve, and is there bisected; but it is only in the case of the circle that all diameters are equal. In the parabola, since the centre of the curve is at an infinite distance, all diameters are parallel to the axis.

**Diamond** is a natural form of crystallised carbon, highly valued as a precious stone, today of more value than the ruby. The diamond crystallises in the cubic or monometric system, its common forms being the regular octahedron, the rhombic dodecahedron, and the six-faced octahedron. The faces are often curved, and the general form of the crystal may be more or less rounded. Cleavage is perfect, parallel to the faces of the octahedron—a fact which is often taken advantage of in splitting off fragments for the purpose of removing flaws. The surface of the diamond frequently exhibits striae and triangular impressions, while the interior may contain microscopic cavities and various inclusions. A distinctly lamellar structure is by no means uncommon.

The lustre of the diamond is peculiar to itself, and hence termed 'adamantine.' In a natural condition, however, the surface often presents a dull lead-gray semi-metallic lustre. The high refractive and dispersive powers of the diamond produce, when the stone is judiciously cut, a brilliancy and 'fire' unequalled by any other stone. The mean index of refraction is 2.417, and the angle of total reflection about  $24^{\circ} 13'$ ; the latter accounts largely for the lustre, inasmuch as a large proportion of the incident light is in a well-cut diamond reflected from the inner surface of the stone. The diamond, especially when coloured, is highly phosphorescent, that is to say, after exposure to brilliant illumination it emits the rays which it has absorbed, and

thus becomes self-luminous in the dark. Under the electric discharge in a highly rarefied medium it exhibits beautiful phosphorescent phenomena, as pointed out by Sir W. Crookes. The diamond also phosphoresces under the influence of radium. It is very translucent to the X-rays, and may thus be distinguished from paste. Some diamonds are fluorescent.

The specific gravity of the diamond is about 3.52, and its degree of hardness greater than that of any other mineral, being indicated by 10 in the ordinary scale. The excessive hardness serves to distinguish the diamond from other gem-stones: any stone which readily scratches ruby and sapphire must be a diamond. Notwithstanding its hardness the diamond is brittle, and hence the absurdity of the ancient test which professed to distinguish the diamond by its withstanding a heavy blow struck by a hammer when placed on an anvil.

Regarded formerly as a peculiar kind of rock-crystal, the chemical composition of the diamond remained for a long time extremely obscure. It was shown by the Florentine academicians Averani and Targioni, about 1695, that the diamond could be volatilised at a high temperature, their experiments having been made at the cost of the Grand-duke Cosmo III.

Newton in 1704 expressed the opinion that the diamond, from its high refrangibility, was probably an unctuous body coagulated. In 1751 the Emperor Francis I. performed an experiment which showed that diamonds strongly heated in a furnace completely disappeared. Lavoisier demonstrated in 1772 that while the diamond is extremely refractory if heated with total exclusion of air, it is readily combustible at a moderate temperature in the presence of air or oxygen, with production of carbonic acid gas. In 1797 Smitson Tennant showed the identity of diamond with carbon. The researches of Dumas, Stas, Roscoe, and Friedel all tended to prove that the diamond is practically pure carbon. Chemists have generally experimented, for sake of economy, with impure specimens, or pieces of board, and have thus obtained on combustion a considerable amount of ash; but the purer the diamond the smaller is the proportion of ash left. Gustav Rose subjected diamonds, inclosed in a vessel free from air, to the intense heat of the voltaic arc, when the gems became gradually incrustated with a dark coating of graphitic matter; and in some cases triangular depressions were developed on the faces, like those often observed in the South African diamond.

Hence it was hoped that carbon might be induced by artificial means to assume the characters of the gem. In 1880 J. B. Hannay of Glasgow produced artificial diamonds by inclosing a mixture of paraffin spirit and bone-oil distillate, with metallic lithium, in a strong wrought-iron tube, and exposing it to prolonged heat in a reverberatory furnace. Specimens of diamantoid carbon were thus obtained, but of small size, and it was found that these, when placed on the wheel, immediately crumbled. Moissan obtained diamond, though in crystals of only microscopic size, by dissolving pure charcoal in pure metallic iron, melted in a powerful electric furnace. On the molten mass being suddenly cooled by plunging into water the carbon separated from solution in the liquid iron, and solidified under intense pressure within the solid crust. The diamond was then separated from the iron in which it was embedded by the tedious process of dissolving away the metallic matrix. J. Friedländer showed that diamond may be obtained, without great pressure, by crystallisation from solution of graphite in fused olivine. R. von Hesslinger and J. Wolf obtained it from a solution of graphite in a fused mixture of silicates, resembling those of the South African matrix.

It is notable that the occurrence of diamonds has been recorded in certain meteorites; one that fell in the Russian government of Penza in 1886 contained 1 per cent. of diamantoid carbon. Diamond was also found in meteoric iron from Canyon Diablo in Arizona.

An imperfect variety of diamond known as *bort*, or *bourt*, occurs in the form of small spherical concretions with crystalline texture. Although unfit for use as an ornamental stone, it is employed when ground as an abrading agent; and the powder mixed with oil serves to feed the lapidary's wheel when cutting hard stones. Much of the bort of commerce is not the mineralogical variety, but consists of splinters, rough fragments, and imperfect crystals of ordinary diamonds. The diamonds used by the glazier for cutting glass are ordinary crystals with rounded faces, and are known as *vitré* diamonds. The cut, though only to the depth of about the  $\frac{1}{16}$ th of an inch, is sufficient to determine with precision the direction in which the glass shall break. Round pieces of bort are of most value.

*Carbon*, or *carbonado*, is the name applied to an opaque, black, granular, or imperfectly crystallised variety of diamond found only in Brazil, where it was discovered in 1843. While its density is less than that of crystallised diamond, its hardness is greater, and hence it is used in the arts, especially for mounting in the steel heads or crowns of the rotary diamond drills for rock-boring.

The art of cutting and polishing the diamond is said to have been discovered in 1456 by Louis de Berquem of Bruges. As formerly practised, the stone was first, if necessary, cleaved or split, and then 'bruted' or rubbed into shape. The faces of the stone thus 'cut' were ground and polished on flat metal discs, fed with diamond dust and oil, and revolving with great rapidity by steam-power. In recent years the process has been greatly modified, and the stone, instead of being subjected to cleaving and bruting, is now usually sawn into the most profitable shape. The saw is a piece of

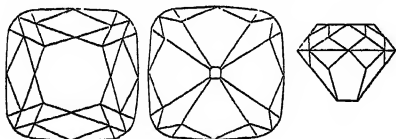

Fig. 1.—Square-cut Brilliant.

very thin steel, supplied with oil and diamond dust, and revolving at great speed by electricity. This process enables the table of the gem to be produced at once, and effects a saving of one-half of the crystal, inasmuch as the piece sawn off is available as another stone, whereas in the older process it was reduced to

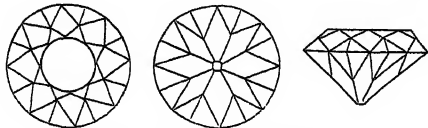

Fig. 2.—Round-cut Brilliant.

dust or practically lost. Amsterdam is the chief home of diamond cutting and polishing, but the trade is also carried on in London, Antwerp, &c. The common form of the diamond is either the *brilliant* or the *rose-cut*. The brilliant resembles two truncated cones, base to base, the edge of the junction being called the *girdle*, the large plane at the top is the *table*, and the small face at the base the *culet*; the sides are covered with symmetrical

facets. Fig. 1 shows a square-cut brilliant, and fig. 2 a round-cut brilliant. The rose has a flat base, with sides formed of rows of triangular facets rising as a low pyramid or hemisphere; but this form of diamond is daily becoming less fashionable. It is illustrated by fig. 3.

India was formerly the only country known which yielded diamonds in quantity, and thence were obtained all the great historical stones of antiquity. The chief diamond-producing districts are those (1) in the Madras Presidency, on the Kistna and Godavari rivers, commonly though improperly termed the Golconda region; (2) in the Central

Fig. 3.—Rose-cut Diamond.

Provinces, including the mines of Sumbulpur; and (3) in Bundelkhand, where the Panna mines are situated.

At present the diamond production of India is insignificant. It is notable, however, that in 1881 a fine diamond, weighing 67½ carats, was found near Wajra Karur, in the Bellary district, Madras. The stone was cut into a brilliant weighing 24½ carats, and is known as the 'Gor-do-Noir.'

Brazil was not regarded as a diamond-yielding country until 1727, when the true nature of certain crystals found in the gold washings of the province of Minas Geraes was first detected. Diamonds occur not only in this province, but in Bahia, Goyaz, Matto Grosso, and Paraná. The geological conditions under which the mineral occurs have been carefully studied by Professors Derby, Gorceix, and Chatrian. The diamonds are found in the sands and gravels of river-beds, associated with gold, specular iron ore, rutile, anatase, monazite, topaz, and tourmaline. In 1853 an extraordinary diamond was found by a negress in the river Bogagem, in Minas Geraes. It weighed 254½ carats, and was cut into a brilliant of perfect water, weighing 125 carats (see fig. 4, b). This brilliant, known as the 'Star of the South,' was sold to the Gaikwar of Baroda for £80,000.

Both the Indian and the Brazilian diamond-fields have been eclipsed by the remarkable discoveries of South Africa (see CAPE OF GOOD HOPE). Although it was known in the 18th century that diamonds occurred in certain parts of South Africa, the fact was forgotten, and when in 1867 they were found near Hopetown, the discovery came upon the world as a surprise. The principal mines are situated in Griqualand West, but diamonds are also worked in the Orange Free State and in the Transvaal. They occur near Gwelo in Rhodesia, and in South-west Africa. The 'river diggings' in the Vaal and Orange rivers have occasionally yielded large stones; one found in 1872 on the Vaal weighed 288½ carats, and yielded a fine pale yellow brilliant, known as the 'Stewart.'

It was soon found that the diamonds of South Africa were not confined to the river gravels, and 'dry diggings' came to be established in the so-called 'pans.' The principal mines are those of Kimberley, De Beer's, Du Toit's Pan, Bultfontein, and Wessleton. At these localities the diamonds occur in a serpentinous breccia, filling pipes or 'chimneys,' generally regarded as volcanic ducts, which rise from unknown depths and burst through the surrounding shales. The 'blue ground,' or kimberlite, is a volcanic breccia containing fragments of various rocks cemented by a serpentinous paste: this ground becomes altered by meteoric

agents as it approaches the surface, and is converted into 'yellow earth.' At Kimberley the neighbouring schists, or 'reefs,' are associated with sheets of a basaltic rock, which are pierced by the pipes. In the early days of the diamond industry in South Africa the blue earth was worked in huge open pits, but about 1889 this quarrying gave place to mining by deep shafts and tunnels. The earth when raised is spread over great distributing floors, where it is disintegrated by weathering, and the friable material is then washed in pans and concentrated in the pulsator. The diamonds are separated by adhesion to grease spread over the percussion tables across which the material travels.

The great number of large stones found in the mines of South Africa is a striking peculiarity. The largest diamond hitherto yielded by South Africa is the famous *Cullinan* diamond, which was found on 25th January 1905 at the New Premier mine in the Transvaal, about 20 miles WNW. of Pretoria. This limpid stone, apparently part of a large octa-

tion, and reappeared a century later cut into three stones. The greater portion, 41½ carats, turned up as the Hope Blue Diamond, while about 11 carats was purchased at the late Duke of Brunswick's sale, and the writer of this article bought in Paris 1½ carats for £300. The Hope Diamond realised £32,000, but brought ill-luck to its purchasers, all of whom came to violent ends.

Of all the great diamonds, the 'Koh-i-nur' is perhaps the most interesting (see fig. 4, c). While tradition carries it back to legendary times, it is known from history that the Sultan Ala-ed-din in 1304 acquired this gem on the defeat of the Raja of Malwa, whose family had possessed it for many generations. In 1526 it passed by conquest to Humayun, the son of Sultan Baber. When Aurungzebe subsequently possessed this stone, he used it as one of the eyes of the peacock adorning his famous peacock throne. On the conquest of Mohammed Shah by Nadir Shah in 1739 the great diamond was not found among the Delhi

treasures, but learning that Mohammed carried it concealed in his turban, Nadir, on the grand ceremony of reinstating the Mogul emperor on the throne at the conclusion of peace, offered to exchange turbans, in token of reconciliation, and by this ruse obtained possession of the gem. It was when Nadir first saw the diamond on unfolding the turban that he exclaimed, 'Koh-i-nur,' or 'Mountain of Light,' the name by which the gem has ever since been known. At Nadir's death it passed to his unfortunate son, Shah Rokh, by whom it was given to Ahmed Shah, the founder of the Durani Afghan empire. By Ahmed it was bequeathed to his son, Taimur Shah; and from his descendants it

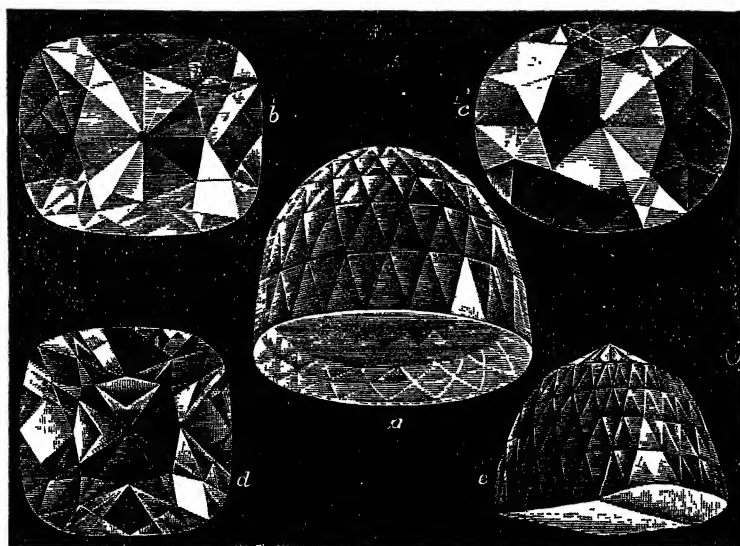

Fig. 4.

hedral crystal, weighed 3025½ carats, or about 1½ lb. avoidupois. It was presented by the Transvaal Government, at the instigation of General Botha, to Edward VII. upon his birthday in 1907. The following year it was cut in Amsterdam by Messrs J. Asscher & Co., and yielded nine large brilliants and numerous small stones. The largest of the cut stones weighed 516½ carats and 309½ carats.

Next to the Cullinan, the largest South African diamond is the *Excelsior*, a stone which in its rough state weighed 971 carats, and was found in 1893 at the Jagersfontein mine in the Orange Free State.

The Australian stones are small and harder than other diamonds. Victoria, Queensland, and South Australia have yielded diamonds, but only in New South Wales have the drifts been worked, Bingera being the first notable working. The tin-gravels of Inverell were afterwards worked for diamonds.

A few special diamonds from their size, colour, and history deserve notice. The first blue diamond of value heard of in Europe was considered unique. In the rough it weighed 112½ carats, and was described as *d'un beau violet*. It was bought by Louis XIV. in 1668, and was then cut into a brilliant of 67½ carats. This was stolen during the revolu-

tion, after a series of romantic incidents, to Runjit-Singh. On the death of Runjit, in 1839, the diamond was preserved in the treasury of Lahore, and on the annexation of the Punjab by the British in 1849, when the property of the state was confiscated to the East India Company, it was stipulated that the Koh-i-nur should be presented to the Queen of England. It was consequently taken in charge by Lord Dalhousie, who sent it to England in 1850. After the Great Exhibition of 1851, where it had been exhibited, it was injudiciously re-cut in London by Voorsanger, a skilful workman from Messrs Coster's factory at Amsterdam. The re-cutting occupied 38 days of 12 hours each, and the weight of the stone was reduced from 186½ to 106½ carats. The form is that of a shallow brilliant, too thin to display much fire. According to Lady Burton, it is believed to bring ill-luck to its possessor.

Another famous Indian diamond is the 'Great Mogul' (fig. 4, a), which appears to have been found about 1650 in the Kollur mine, on the Kistna. It was seen by the French jeweller Tavernier at the court of Aurungzebe in 1665, and is described as a round white rose-cut stone of 280 carats. Its sub-

sequent history is unknown, and it is probable that at the sacking of Delhi by Nadir Shah in 1739 it was stolen and broken up. Some authorities have sought to identify the Great Mogul with the Koh-i-nur, and others with the Orloff.

The 'Orloff' (fig. 4, e) is an Indian stone which was purchased at Amsterdam in 1776 by Prince Orloff for Catharine II. of Russia. The stone at one time formed the eye of an idol in a temple in the island of Seringham, in Mysore, whence it is said to have been stolen by a French soldier. It weighs 193 carats, and was mounted in the imperial sceptre of the Tsar.

The 'Regent' is a famous diamond preserved among the national jewels in Paris. It was found in 1701, at the Partael mines, on the Kistna, by a slave, who escaped with it to the coast, where he sold it to an English skipper, by whom he was afterwards treacherously killed. Thomas Pitt, grandfather of the first Earl of Chatham, at that time governor of Fort St George, purchased the stone, and had it re-cut in London, whence it is often known as the 'Pitt.' Its original weight was 410 carats, but it was reduced in cutting to 136½; the result, however, was a brilliant of fine water and excellent proportions. Pitt sold it in 1717, through the financier John Law, to the Duke of Orleans, then Regent of France during the minority of Louis XV.

The large 'Sancy' is an historical diamond, about which many contradictory stories have been told. It appears that the Sancy was an Indian stone, purchased about 1570 by M. de Sancy, French ambassador at Constantinople. It passed temporarily into the possession of Henry III. and Henry IV. of France, and was eventually sold by Sancy to Queen Elizabeth of England. By James II. it was disposed of to Louis XIV., about 1695, for £25,000. At the beginning of the 19th century it passed to the Demidoff family in Russia, and by them it was sold in 1865 to Sir Jamsetjee Jeejeebhoy.

Of coloured diamonds there are a few possessing historical interest. Diamonds occur of all tints, and when the colour is well pronounced, they are prized as fancy stones. A pale green diamond, weighing 48½ carats, is preserved in the Green Vaults at Dresden. But one of the most superb coloured diamonds at present known is the sapphire blue brilliant termed the 'Hope' diamond, which formerly belonged to Mr H. T. Hope, and weighs 44½ carats. It is believed to have been cut from the large blue diamond, weighing in the rough 112½ carats, sold by Tavernier to Louis XIV., which disappeared amid the troubles of 1792.

For further information on the blue diamond, see *Precious Stones and Gems*, page 139; and on historical diamonds, see *The Great Diamonds of the World*, by E. W. Stieler; French works by Jacobs and Chatrain (1884) and Boutan (1886); and Kunz, *Gems and Precious Stones* (New York, 1900). For South Africa, see Gardner Williams, *The Diamond Mines of South Africa* (1906), and Sir William Crookes, *Diamonds* (1909).

**Diamond Beetle.** See WEEVIL.

**Diamond Harbour,** a port and telegraph station on the Hûghl, 38 miles SSW. of Calcutta by rail, 41 by river. Formerly, the Company's ships anchored here.

**Diamond Necklace,** THE, a wonderful piece of jewelry, made in Paris about the year 1775, and intended for Madame Dubarry, the favourite of Louis XV. She, however, was excluded from court on the death of Louis (1774), before the necklace was finished. After being made, this beautiful ornament, adorned with 500 diamonds, was found to be so costly that no one could purchase it. It was valued at 1,800,000 livres, equal to about £80,000 of modern money.

The Prince Cardinal de Rohan, a wealthy, vain,

and profligate man, persuaded by an adventuress named De Lamotte, who waited about court, that the queen (Marie Antoinette) regarded him with favour, became completely infatuated with the idea. One night in August 1784 the poor dupe had the happiness of a moment's interview in the groves around Versailles with the queen in the person of a girl who closely resembled her. De Lamotte had stated to the cardinal that the queen was desirous of obtaining this glorious necklace, and that not having sufficient money just then, she would sign an agreement to purchase it if the cardinal would become security. The cardinal consented. The agreement was approved of and signed with the royal signature, as also with that of the cardinal, who, on the 1st February 1785, carried off the treasure from the maker to Versailles, where it had been agreed the queen should send for it. In a few days De Lamotte and her husband, having disappeared from Paris, were busily engaged in selling the separate diamonds in the necklace. The whole transaction had been a trick; the messages from the queen, oral and written, were without foundation, the latter, indeed, being forged by a *soi-disant* valet, who was skilled in imitating handwriting. The plot was discovered by means of the maker of the diamond necklace, who, not receiving any money when the period of the first instalment had arrived, went to court, demanding to know if the necklace had been delivered to the queen. In a few months the cardinal found himself in the Bastille, where some of those by whom he had been duped had already been lodged. In May 1786 the trial of the prisoners was brought to a close. De Lamotte was branded on each shoulder with the letter V (for *voleuse*, 'thief'), and was sentenced to perpetual imprisonment. Her husband, who had fled to England, was sentenced in his absence to the galleys for life. The cardinal and the girl who had personated the queen were dismissed without punishment. The queen was falsely supposed by the populace of Paris to have had a part in the plot, and the odium resulting from it was heaped upon her, even at the last, when she sat on the tumbril that bore her through a raging and cursing mob to the guillotine.

See Carlyle's study, in his *Essays*; Vizetelly's *Story of the Diamond Necklace* (new ed. 1880); and French works by Campardon (1863), D'Este Ange (1889), and Brentano (trans. 1902).

**Diamper.** See THOMAS (CHRISTIANS OF ST.).

**Diana,** an ancient Italian divinity, identified by the Romans with the Greek Artemis. She was a goddess of light, and represented the moon. It is said that Servius Tullius was the first to introduce her worship at Rome, and apparently she was first worshipped by patricians only. See ARTEMIS.

**Diana** (1) OF POITIERS, a favourite of Henry II. of France, was born in 1499, the eldest daughter of Jean de Poitiers. Married at thirteen, she became a widow at thirty-two, and ere long attached the affections of the nineteen years younger dauphin strongly to herself. On his accession as Henry II. (1547) Diana enjoyed great influence, did much to reform the court, and brought its influence to bear strongly against the reforming party. She was made Duchess of Valentinois in 1548, retired from court to her castle Château d'Anet on the king's death in 1559, and died in 1566. The splendid Château de Chenonceaux (q.v.) was given her by the king, but after her death was taken by Catharine de' Medici. It still contains many memorials of its most famous mistress.—(2) **DIANA OF FRANCE**, Duchess of Angoulême, was born in 1538, natural daughter of Henry II. and

a Piedmontese (according to others, of Diana of Poitiers), was formally legitimised, and married first to a son of the Duke of Parma, next to the eldest son of the Constable de Montmorency. She enjoyed great influence at court under Henry IV., superintended the education of the young prince, afterwards Louis XIII., then retired from court, and died without issue in 1619.

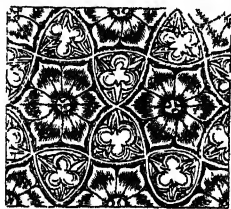

**Dianthus.** See CARNATION, PINK.

**Diapa'son** (Gr.), a term in music by which the ancient Greeks designated the octave. The French use the term as equivalent to *pitch*. Diapason is also the English name given to the fundamental stops of the Organ (q.v.).

**Diaper**, a term applied to certain forms of flat or slightly relieved ornament. Any pattern formed of a floral, leafy, geometric, or other device, repeated over a flat surface, is called *diaper* or *diaper work*; but according to some authorities the device should be free from bounding lines forming squares, as a pattern of this nature should rather be called *checker* or *checker work*.

In *textile fabrics* the term appears to have been given at one time to silk fabrics with almost any kind of repeated pattern upon them. It is an older name for figured silk than Damask (q.v.). The Byzantine Greeks seem to have called a silk with both pattern and ground of one colour *diaspron*, and the Latins, following the Greeks, named such a fabric *diasper*, which through Old French became the English word *diaper*. Chaucer refers to 'cloth of gold diapered wele' (*Knight's Tale*). Any kind of textile fabric, paper, or leather, with a more or less enriched geometrical pattern is, in a general way, said to be diapered. But as regards textiles the term diaper nowadays is almost confined to undyed linen with a woven diamond pattern, although cotton imitations are made. According to the size of this pattern the stuff is called bird's-eye, pheasant's-eye, fish-eye, or Russia diaper.

In Architecture, diaper-work, or diapering, is a kind of decoration applied to plane surfaces, and consists of a small repeated pattern either of conventional flowers, leaves, or other devices, carved or painted. The flower, or other object, is generally inclosed by lines, fillets, or slender mouldings, which constitute in themselves a sort of geometrical diapering. When the pattern is carved, it is generally sunk; and when painted, it consists of a darker shade of the same colour as the plane surface, by which the effect of shadow is communicated to it. The accompanying illustration, from Bloxam's *Gothic Architecture*, exhibits a very beautiful example of Decorated English diapering. It is taken from Canterbury Cathedral.

Diaper.

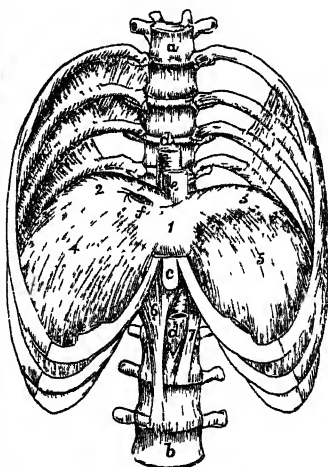

**Diaphony**, a primitive form of Descant (q.v.), in which the parts progressed in similar motion.

**Diaphoretics.** See SUDORIFICS.

**Diaphragm**, or MIDRIF (Gr. *diaphragma*, 'a partition'), is the name applied in anatomy to designate the musculo-tendinous partition which in man and the mammalia generally separates the cavity of the thorax from that of the abdomen. Its general form is that of a *dome* directed towards the chest, the lower part and sides being muscular, while the central or highest portion consists of an expanded tendon. The muscular fibres have an extensive origin from the circumference of the

visceral cavity—viz. posteriorly, a *vertebral* portion arising from the lumbar vertebrae by two pointed processes, or *crura*, of unequal length, and from two fibrous bands, or *arched ligaments*, on each side of the bodies of the vertebrae: laterally, a *costal* portion arising from the cartilaginous and adjoining osseous parts of the lower six ribs; anteriorly, a

*sternal* portion arising from the ensiform cartilage of the sternum, or breast-bone. From these various points the muscular fibres converge to the *central, trefoil*, or *cordiform tendon*, which forms the highest part of the diaphragm, and as its name indicates, consists of three *lobes*. The diaphragm presents three large perforations or *foramina*; one, *quadrilateral*, placed in the highest part of the tendinous centre for the upward passage of the inferior vena cava; one, *oval* in form, surrounded by

The lower part of the Thorax, opened to show the upper side of the Diaphragm from before:

a, sixth dorsal vertebra; b, fourth lumbar vertebra; c, ensiform cartilage; *dd*, aorta; e, oesophagus; f, opening for inferior vena cava. 1, 2, 3, trefoil tendon; 4, 5, central portions of diaphragm; 6, right, and 7, left crus of diaphragm.

muscular fibres derived from the *crura*, for the passage of the oesophagus and pneumogastric nerves; the third, situated in front of the vertebrae and bounded by tendinous fibres of the *crura*, transmits the aorta, thoracic duct, and large azygos vein.

The upper surface of the diaphragm is in relation to the pleural membranes which inclose the lungs, and the pericardium which incloses the heart. The latter membrane is intimately connected with the central tendon, which thus forms a fixed floor for the support of the heart. The lower surface, deeply concave in form, is lined by peritoneum, and has in apposition with it the stomach and spleen on the left side, the convex upper surface of the liver on the right side, and the kidneys, supra-renal capsules, and duodenum posteriorly.

When the diaphragm contracts, the arched portion becomes flatter, and the cavity of the chest being thereby enlarged, air rushes in to fill the vacuum, and expands the lungs during the act of inspiration. It is thus an inspiratory muscle, and in ordinary quiet breathing the central tendon on which the heart rests takes no share in this movement. Every contraction of the diaphragm must diminish the abdominal space and compress the abdominal viscera, and hence it aids in the expulsion of the feces and urine.

Spasmodic action of the diaphragm produces hiccough and sobbing. Stoppage of the action of the diaphragm, whether from great external pressure or from paralysis, is very speedily fatal.

DIAPHRAGM, a partition with a hole in it, employed not only in landscape and portrait lenses for photography, but also in telescopes, microscopes, and other optical instruments, for the purpose of cutting off the superfluous rays of light,

and producing greater intensity or sharpness of the image, as well as to correct aberration.

**Diarbekir**, a town of Asiatic Turkey, capital of a province of the same name, is situated on the right bank of the Tigris, 390 miles NW. of Bagdad. The town is surrounded by high strong walls, and commanded by a citadel built on a high basalt rock, against which the flat-roofed houses rise above each other in terraces. The population has dwindled to about 40,000, mostly Kurds and Armenians. The city is the seat of a Greek bishop, as also usually of the Jacobite patriarch of Antioch. It has numerous mosques and churches, bazaars, fountains, baths, and caravanserais, although the last are now falling into decay. Indeed, only in the centre of the town are any of the buildings handsome; elsewhere ruins meet one at every step. Stagnant pools, weeds, and filth combine to produce fevers. Diarbekir had formerly extensive manufactures of silk and cotton goods, which it still produces, and an active commerce with Aleppo and Bagdad; and it still has considerable trade in raw products. The roads to the coast are equally bad and insecure, and the traffic with Bagdad is mostly by raft. The principal exports are wool, mohair, sheep and goats, copper ore, butter, gall-nuts, goat and kid skins, and furs; the imports include cotton and woollen goods, indigo, coffee, sugar, buffalo-hides, petroleum, and soap. Diarbekir occupies the site of the ancient *Amida*, which was fortified by the Emperor Constantine. It was captured by the Persians in 359, and retaken by Justinian; but in 502 the Persians once more became masters, and put 80,000 of the inhabitants to the sword. In 640 it fell into the hands of the Arabs of the Bekr tribe, whose name became identified with the district; but the Turkish official title remained *Kara Amid* ('Black Amid,' from the colour of its basaltic walls). After many vicissitudes, the town passed into the hands of Sultan Selim in 1515.

**Diarrhœa** (Gr. *dia*, 'through,' and *rhœō*, 'I flow') is the name applied to an increase in the discharges from the bowels, which are usually unduly liquid, sometimes overcharged with bile, and sometimes with mucus. It is, properly speaking, a symptom rather than a disease. Thus it often occurs in the course of diseases of the liver and spleen, of some forms of heart-disease, of many fevers and other acute diseases, and is a common complication of the advanced stage of consumption. Frequently, however, it is the most prominent, perhaps the only symptom of ill-health; and it may then take rank as a disease, or rather as the generic name of a group of diseases. In this aspect the subject will be discussed here.

Diarrhœa is either simple, bilious, or choleraic; the last form has already been discussed (see CHOLERA). The ancients applied the name *lentery* to a diarrhœa in which the dejections consisted of matters not digested, or very partially so; this form is, however, very unusual, at all events in Britain. Dysentery (q.v.) is also a form of diarrhœal disease; as is the group of Fevers (q.v.) called typhoid, enteric, and paratyphoid fevers. Simple and bilious diarrhœa probably often differ only in degree; they are both distinguished from the advanced stages of cholera and dysentery by the presence of abundance of biliary colouring matter in the stools, and by the absence of the distinctive features of the other two diseases as described elsewhere. Diarrhœa is almost always accompanied at first by pain in the abdomen, sometimes severe or even agonising in character. According to its cause and treatment, it may pass off in a few hours, or may persist for a few weeks or months; or it may even prove fatal.

Diarrhœa has many varieties and many causes; but the whole class of more or less epidemic diarrhœal diseases is due to the spread of various kinds of bacteria, and has been studied of late years from the bacteriological and sanitary points of view. It is observed of all of these diseases, without exception, that they are more apt to prevail during summer and autumn than during the earlier seasons of the year; and their prevalence is to a great extent dependent on the height of the summer temperature. The crowding together of people with an absence of first-class sanitary arrangements for the disposal of refuse and excreta, as, for example, in camps, also favours its occurrence. The development of flies in large numbers also greatly conduces to the spread of epidemic diarrhœa when it has once broken out. It has been noticed that cold and wet seasons are the least favourable to the production of diarrhœa. Infants are especially apt to suffer from diarrhœa, and a large number of the infantile deaths in many English towns are caused directly by this disease.

Besides these epidemic diarrhœas, isolated cases of simpler and more obvious origin are very frequent. In some persons diarrhœa is the usual result of catching cold—i.e. they suffer from catarrh of the digestive, instead of, as is most usual, the respiratory organs. But far more frequently diarrhœa results from unwholesome or indigestible food or drink, or from excessive indulgence even in what would otherwise not be hurtful. In all such cases the diarrhœa is to be regarded as beneficial; in fact, it is the natural effort of the intestines to rid themselves of their objectionable contents, and should be encouraged rather than arrested. Diarrhœa occurring as an incident in prolonged constipation is to be explained in the same way, as due to irritation of the intestines by their hardened contents. The diarrhœa which affects infants, apart from epidemic outbreaks, is of this nature, and is usually an indication that their food is unsuitable. A rough guide to the nature of the bacterial changes that are in progress in the child's intestines, and that are responsible for the diarrhœa, is obtained by examination of the stools. When the stools are alkaline, fermenting and offensive, milk and starchy foods form the best diet; and when the stools are acid, sour in smell, and green in colour, albuminous fluids, like barley-water and meat-juice, suit best.

Acute diarrhœa should almost always be treated first by an aperient, as the unaided action of the intestines is often insufficient to expel irritating material. A full teaspoonful of Gregory's powder, or a tablespoonful of castor-oil with ten or fifteen drops of laudanum is especially useful. The food taken should be small in amount, and as easily digestible as possible. Milk, arrowroot, &c., beef-tea, toast, plain biscuits, are among the most suitable articles of diet. Complete abstinence from food for a day or more, which has the effect of resting the bowels and preventing the presence of putrefactive material, is, when combined with rest in bed, one of the most satisfactory methods of treating diarrhœa. Pain may be alleviated by poultices or fomentations sprinkled with laudanum. A small dose of brandy often checks both the pain and the diarrhœa. Should the disease not yield to these measures, opium, carminatives, and astringents should be administered. In some cases, especially of febrile diarrhœa, an emetic of ipecacuanha at the very beginning will sometimes remove the disease with remarkable rapidity; and in most forms of diarrhœa it may be alleged that this medicine (in doses of from one to five or even ten grains) is well borne. Sometimes it is combined with opium in the form of Dover's powder. In chronic diarrhœa (not the consequence of serious

organic disease) careful regulation of the diet is of prime importance, and is generally accompanied by the administration of astringents. But such cases are often very intractable, and no rules can be laid down that would apply to all. In a very large class of cases, especially of infantile diarrhoea, depending upon a too acid state of the intestinal contents, the leading remedy is chalk, either in powder or in the very serviceable form of the *mistura cretæ* (mixture of chalk) of the *pharmacopœias*, from one to three dessert-spoonfuls of which may be given after every disturbance of the bowels. Lime-water, mixed with milk in the proportion of one to four or five, is easily given to very young children, and serves nearly the same purpose.

The astringents useful in diarrhoea are very various. Those of vegetable origin are usually first employed, alone or in combination. The most important are tannic and gallic acids, kino, catechu. The mineral astringents are chiefly salts of the heavier metals, iron, bismuth, copper, lead, &c.; but also chalk and lime, and alum. Opium, one of the most powerful remedies, owes its usefulness to other than astringent properties, and is very frequently given in combination with astringents—e.g. in chalk and opium powder, compound kino powder, lead and opium pills. In many states of the system in which diarrhoea occurs, however, it is dangerous. It must never be given to young children, or in large doses to any one, without medical advice. In some forms of diarrhoea, especially in children, antiseptics are very useful—e.g. grey powder, creasote; and it is probably to its antiseptic properties that corrosive sublimate (bichloride of mercury) owes its value when administered in minute doses.

**Diary** (Lat. *diarium*, 'a daily allowance for soldiers,' 'diary,' from *dies*, 'a day') means simply a daily record of events or observations made by an individual. In it the man of letters inscribes the daily results of his reading or his meditations; to the mercantile man it serves the purpose of an order or memorandum book; while the physician finds it indispensable as a register of engagements. Diaries in many forms and sizes are issued every year, containing also so much miscellaneous information that in one book we have at once a diary and an almanac. The *Ephemeris* of the ancients was originally a military record or journal, a day-book or account-book, also a collection of tables showing the position of the heavenly bodies, but passed into literature to mean a collection of records of what has happened on the same day in various years, or a mere general name for any form of periodical books or magazines.

Diaries have often furnished the historian with invaluable material, supplying the absence of public records, and furnishing minute and intimate details of manners and of motives that do far more to help us to understand the past than more formal records. Such documents as Robert Baillie's *Journals*, the *Diaries* of Pepys and Evelyn, and the *Journals* of Greville are among the most valuable sources of real history. Bacon says 'in sea-voyages, where there is nothing to be seen but sky and sea, men make diaries; but in land-travel, wherein so much is to be observed, they omit it,' but unhappily this no longer holds of modern travellers.

**Diastase**, or **AMYLASE**, is the enzyme which converts starch into sugar (see **FERMENTATION**). It is found chiefly in germinating seeds, in which its function is to convert the insoluble starch stored up in the seed into soluble sugar, which is available for the needs of the growing seedling. It also occurs in the green leaves and other parts of plants. The best-known diastase is that which

occurs in malt (see **BEER**), by the aid of which, in the process of brewing, the starch of the malt is saccharified, and thus rendered capable of being fermented by yeast. Malt extract, prepared by extracting the ground malt with cold or lukewarm water, contains the enzyme, and finds many medicinal and dietetic applications. Malt diastase is precipitated, along with other substances, when alcohol is added to malt extract, and can thus be obtained as a dry, white powder. It converts starch first into a mixture of dextrins and the sugar maltose, and finally into maltose. A similar enzyme, known as *takadiastase*, is obtained from a mould (*Aspergillus oryzae*), and has a more energetic action than malt diastase on starch, which it converts finally into grape sugar, not maltose. It has long been used by the Japanese in the brewing of their national drink, saké, from rice. See **GERMINATION**, **COOKERY**, **DIGESTION**, **FERMENTATION**.

**Diathermancy.** See **HEAT**.

**Diathesis** (Gr. *dia*, 'through,' and *tithēmi*, 'I place or arrange'), a Greek word signifying a disposition or arrangement, and applied by the old medical authors to the predisposition or constitution of the body which renders it prone to certain diseased states. By recent writers the term is applied to the general constitutional tendency of an individual, to indicate not merely the class of diseases to which he is most likely to be liable, but also in many cases the manner in which his normal functions, both bodily and mental, are carried on; and is thus opposed to Cachexia (q.v.), an unhealthy condition associated with actual disease. Though the study of diathesis apart from existing disease is very apt to lead to over-refinement and the pursuit of intangible abstractions, yet a proper appreciation of a person's constitutional proclivities or diathesis often enables a medical man to advise him how to regulate his life and habits to the best advantage—what to do and what to avoid—and may furnish important guidance as to his treatment in disease. The diatheses most usually recognised are the sanguine, the nervous or neurotic, the bilious, the lymphatic, the strumous, and the hæmorrhagic. Numerous mixed varieties are also described by some writers.

**Diatoms** (*Diatomaceæ* or *Bacillariaceæ*) are a group of about 10,000 species and varieties of *Algae* abounding in water or wet places in every part of the world, and although of varied form, they possess unique characteristics. The individuals are microscopic, but their presence is often revealed to the unaided eye by the brownish hue which they frequently impart to submersed or wet objects, on which they grow in enormous numbers. Each individual consists of protoplasm, nucleus, cell-sap in special cavities of the protoplasm, chromatophores, and oil-globules. The chromatophores, which may occur as tiny granules, or as one or more larger bodies of varied shape, contain the chlorophyll, which, however, is usually masked by a yellow-brown pigment (diatomin), for which reason they are not termed chloroplasts. The oil-globules answer to the starch grains of many other plants in that (1) they are the product of carbon assimilation carried on by aid of energy derived from the sun; and (2) they form a reserve of food material for the life, growth, and reproduction of the diatom. The organs just enumerated constitute the active portion of the individual or energid, and differ in minor degree only from those of other plants. They are, however, enclosed and protected by a cell-wall of such peculiar composition, and unique form and structure, as to constitute the characteristic feature by which diatoms are distinguished from all other organisms. This cell-wall consists of an organic substance allied to

cellulose more or less impregnated with silica, and the unique peculiarity lies in the fact that each energid is usually enclosed by two of these siliceous shells of nearly equal size, known as valves. The margin, called the girdle-band, of the older and usually slightly larger valve fits over the girdle-band of the younger like lid and body respectively of an ordinary pill-box, the pair being held together by their overlapping girdles. The complete organism thus composed of energid, two valves, and two overlapping girdles is termed a frustule. The siliceous valves in valve or face view may in the different species be discoid, elliptical, lanceolate,

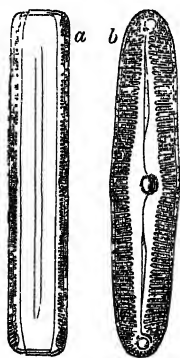

Fig. 1.

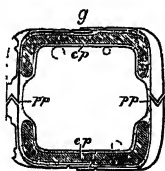

Fig. 2.

An elliptical fresh-water diatom—*Pinnularia viridis*, magnified 470 diameters: 1, a, Girdle view of a frustule, showing overlapping girdle-bands of the two valves, the transverse markings of which are seen on either side; b, valve view, showing central and polar nodules between which runs the median cleft or raphe, its ends being curved in the polar nodules, while a longitudinal area of clear silic runs along each side of it. The transverse striae or markings seen at the sides are really elongated chambers in the silic, each having a tiny pore opening into the interior of the frustule.

2, Diagrammatic transverse section of a frustule; pp, clear protoplasm (lightly shaded) lining the interior of the frustule and containing the large chloroplasts cp (darkly shaded); g, girdle-bands. Opposite pp the raphe is shown as a cleft in the clear siliceous valves which, on the left, exhibit a chamber on each side of the raphe, while on the right the section has passed between the chambers.

linear, triangular, quadrangular, polyangular, or of almost any shape imaginable. Each valve may consist of two or more layers of silic with a complex intermediate structure, or it may be of one somewhat thicker layer provided with minute cavities of very varied size, form, and complexity of structure usually placed in rows, the rows being generally arranged in geometrical designs of extraordinary beauty. Other markings also are of frequent occurrence, such as ribs, bosses, depressions, &c., often placed symmetrically with the cavities. Some species possess spines, horns, or similar processes; others have large protuberances with clear areas at the apex, termed ocelli. Others, again, have minute granules of siliceous matter resembling hoar-frost or tiny spicules scattered over, or almost completely covering the valves.

Besides the internal protoplasm, there is a delicate external protoplasmic mucus either covering the frustule or occurring merely as bands or cushions. In some species this substance is elongated and hardened into a stalk, fixing the organism to the substratum. The same material in other species forms amorphous gelatinous masses, or somewhat firmer gelatinous tubes, in which innumerable individuals are enclosed. In some colonial forms these tubes are much branched, and, being attached by the base to the substratum, resemble in size and shape such filamentous Algae as *Cladophora*. A more common colonial form occurs by the indi-

viduals adhering to one another, by means of tiny mucus cushions on their valves, forming curved, straight, or zigzag filaments of variable length fixed at one end, or floating entirely free.

In the greater number of species the individuals are separate from one another, and certain of the elongated forms may by their own energy be endowed with a small power of locomotion, enabling them to glide over the substratum, while others by floating are transported vastly greater distances by currents. The mechanism of the gliding movement just mentioned has never been satisfactorily demonstrated, but it seems to be due, in some species at any rate, to the protusion of protoplasm through a longitudinal fissure, called the raphe, conspicuous in the valves of those species endowed with that power (fig. 1, b).

The inflexible nature of the siliceous valves when completed usually inhibits their further growth or division; multiplication occurs, therefore, in a remarkable way. The division of an individual into two is initiated by mitosis of the nucleus followed by bipartition of the protoplasm as in the cell division of most other organisms. This takes place within the siliceous shell, the valves of which become slightly separated. Each new energid forms one new valve, the margin of which fits inside that of the pre-existing valve, so that two valves, each with a new girdle-band, are formed within the old girdles of the original frustule. Each individual diatom consists, therefore, of an old and a new valve, the girdle-band of the old overlapping that of the new (fig. 1, a). As the two new valves are formed within a pre-existing frustule they are generally somewhat reduced in size at every division, to which may be ascribed the well-known variation in size of the individuals of a species. This method of bipartition may continue from about twenty-five to fifty or more generations in one season, and such fecundity accounts for the prodigious numbers that occur in every suitable spot; for, in the first case, nearly 17 millions will arise from a single individual, and in fifty generations almost 563 billions. In the cycle of generations, however, numerous losses doubtless occur through enemies or accident, reducing the theoretical limit of progeny from a single original. The restriction in the number of generations limits the diminution in size of the frustules, and when the smallest has been attained for any particular species the largest size is regained by the formation of certain spores called auxospores. These are usually produced after partial or complete conjugation of two of the micro-frustules, and the process may occur in five different ways. The auxospores ultimately germinate and give rise to a sporangial frustule, which moults its temporary shell and soon becomes an individual diatom of the maximum size for the species; it then multiplies by bipartition as previously explained.

Recent investigations on the Diatomaceae of the North Sea reveal the fact that these organisms occur in prodigious abundance; of *Nitzschia delicatissima*, for example, 1½ millions occurred in one quart of water from the open sea, besides many other species in less abundance. Bearing in mind these figures, along with the rate of multiplication previously mentioned, one can the more readily imagine how the vast deposits of these shells, known by geologists to occur in various parts of the world, have been rendered possible. Among such deposits, formed originally at the bottom of seas or lakes by the gradual accumulation of shells of dead diatoms falling from the upper photic stratum of the water where they lived, the following may be mentioned: The soft and friable berg-mehl of Norway, Lapland, Siberia, and other parts of the world, often forming strata 10 to 30 feet

thick. The harder and even more extensive deposits at Richmond, Monmouth, Virginia, and elsewhere in U.S.A. The extremely hard polishing-slates of Tipoli. The well-known deposits at Moir and Nykjöbing in Jutland, Simbirsk in Russia, St Peter in Hungary, Morón in Spain, Sendai in Japan, Oamaru in New Zealand, are all noted for the beauty of the specimens obtainable from them. In various other parts of the world occur deposits of guano, marl, clay, kieselguhr, cement-stone, Turkey-stone, polishing-slates, &c., containing a large proportion of diatoms, and frequently enriched with extraordinary forms. At home we have many deposits of diatomite, but on a smaller scale; those at Lough Moune, Toome Bridge, and Dromore in Ireland, Glenshira, Kinnord, Skye, Mull, Ballateer, and Loch Leven in Scotland, are, among others, well known to diatomophiles. Similar deposits, some even on a more gigantic scale than those already mentioned, are being laid down in all parts of the world at the present time. Although so abundant now, and in the more recent geological times, there is no exact evidence of diatoms in rocks older than those of the Cretaceous epoch, and the great deposits mentioned above are mostly in Tertiary rocks.

Regarding their phylogeny, some thinkers imagine the diatoms to have originated from certain forms of the Peridineales now represented by such species of that group as *Euxivallea marina*, while others associate them with Desmids.

The literature on diatoms is enormous, and a complete bibliography dating from, say, 1830, would contain, at least, 4000 titles—a tribute to the interest they awaken in microscopical and other scientific circles. Of these works some of the following may be found in large libraries: Smith, *British Diatomaceae*, Pritchard, *Infusoria* (4th ed.); O'Meara, *Irish Diatomaceae*; Wolle, *Diatoms of North America*; Van Heurck, *Treatise on Diatoms*; and *Synopsis des Diatomées de Belgique*; Cleve, *Synopsis of Naviculoid Diatoms*; Tempère, *Le Diatomiste*; Schmidt, *Atlas der Diatomaceen-Kunde*; Pantocksek, *Beiträge zur . . . fossilen Bacillarien*; Castracane, *Report on Diatoms* ('Challenger' Expedition); Griffith and Henfrey, *Micrographic Dictionary* (3d and 4th ed.); and all the larger works on the microscope. See ALGÆ, DESMIDS, DYNAMITE, OOZE.

**Diatonic** (from the Greek) means 'by tones,' or 'from tone to tone.' The diatonic species of the ancient Greeks—as distinguished from their chromatic and enharmonic species—formed the foundation of their whole system of music, and was arranged in tetrachords (embryo *scales*) composed of one semitone and two whole tones. In modern music, the term is applied to (1) the natural or normal scale, major or minor, which proceeds mainly by whole tones; (2) the different species of intervals (usually reckoned as fourteen in number) occurring between the various notes of that scale; and (3) music written wholly or for the most part in that scale.

**Diaz**, or DIAS, BARTOLOMEU, a Portuguese navigator of noble birth who flourished during the latter half of the 15th century. His residence at the court of King John II. brought him into contact with many scientific men, among others the German cosmographer Behaim (q.v.). Diaz took a great interest in geographical discovery, and in August 1486 the king gave him the command of two vessels with a view to following up the discoveries already made by Portuguese adventurers on the west coast of Africa. Diaz soon reached the limit which had been attained in South Atlantic navigation, and first touched land in 26° S. lat. Driven by a violent storm, he sailed round the southern extremity of Africa (see CAPE OF GOOD HOPE) without immediately realising the fact, and discovered Algoa Bay. The discontent of

his crew compelled him sorrowfully to return; and arriving in Lisbon, December 1487, he was at first greeted with enthusiasm, but soon saw Vasco da Gama preferred before him, and was compelled to act under the latter in the grand expedition of 1497. Vasco da Gama even sent him back to Portugal after they had reached the Cape Verde Isles. Three years after, he joined the expedition of Cabral, the discoverer of Brazil, but was lost in a storm, 29th May 1500.

**Díaz**, PORFIRIO, born at Oaxaca, 15th September 1830, President of Mexico 1877–80, was repeatedly re-elected, but his administration being felt to be too autocratic, a revolutionary movement compelled him to resign in 1911. He died in Paris 2d July 1915. See Life by D. Hannay (1917); and the article MEXICO.

**Díaz de la Peña**, NARCISO VIRGILIO, painter, was born at Bordeaux in 1807, of Spanish parentage, and, left an orphan at the age of ten, was educated by a Protestant clergyman at Bellevue, where a snake-bite occasioned the amputation of a leg. At the age of fifteen he was apprenticed to a porcelain-painter, but he was ambitious of working in oils, and about 1831 began to exhibit in the Salon. Abandoning his unsuccessful efforts in the direction of history and *genre*, he in time won fame by his landscapes, which he peopled with nymphs, loves, and satyrs. These figures are badly drawn, but as a colourist Diaz ranks highly among the painters of the Romantic school in France, and to colour he was content frankly to sacrifice form. He was also an exquisite painter of flower-pieces. He died at Mentone, 18th November 1876.

**Díaz del Castillo**, BERNAL, the historian of the conquest of Mexico, was born about 1492, and was one of the handful of heroes who accompanied Cortés to Mexico in 1519. He fought through the whole struggle, and afterwards accompanied the heroic young Sandoval on his expedition northwards, and Cortés himself in his expedition to Honduras to punish the defection of his trusted lieutenant, Cristóbal de Olid. He died in Mexico about 1560. His *Historia Verdadera de la conquista de la Nueva España* (1904), written at the age of eighty-four, is invaluable to the historian as a sincere narration by an eye-witness and sharer in the events narrated. With all the ignorance and superstition of its age, it reveals great powers of observation and of vivid and vigorous description; while the rare romantic interest of the story itself, the heroism of Cortés and his companions, and their wonderful deeds, make the book a real epic. See Maudslay's translation (1908–16), and the Life by Cunningham Graham (1915).

**Dibdin**, CHARLES (1745–1814), song-writer, born at Southampton, early attracted notice by his singing, and, still a boy, composed an operetta, *The Shepherd's Artifice*, which was produced at Covent Garden in 1762. He subsequently lived an unsettled life as an actor and composer of stage-music. In 1788 he began a series of musical entertainments, which acquired great celebrity. He retired in 1805 with a pension of £200 granted him two years before; it was withdrawn in 1807, and Dibdin returned to public life with unfortunate financial results. He wrote nearly a hundred songs—among the best *Poor Jack* and *Tom Bowling*—and about seventy dramatic pieces.—Two of his sons, CHARLES (1768–1833) and THOMAS JOHN (1771–1841), wrote songs and dramas. See Dibdin's Autobiography (4 vols. 1803) and *The Dibdins*, by E. R. Dibdin (1888).

**Dibdin**, THOMAS FROGNALL, the bibliographer, was nephew of Charles Dibdin, the writer of sea-songs, and was born at Calcutta in 1776. He lost

both parents when hardly four years of age, his father's death at sea having given Charles Dibdin the subject for his famous song, *Tom Bowling*. He was brought up by a maternal uncle, studied at St John's College, Oxford, tried law, but took orders in 1804. He proceeded D.D. in 1825. Of his precepts the chief were the vicarage of Exning near Newmarket, and the rectory of St Mary's, Bryanston Square, London. He died 18th November 1847. His first contribution to bibliography was an *Introduction to the Greek and Roman Classics* (1802), which was followed by an unfinished new edition of Ames and Herbert's *Typographical Antiquities* (4 vols. 1810-19); *Bibliomania* (1809); *The Bibliographical Decameron* (1817); *Bibliotheca Spenceriana* (1814-15); *Bibliographical, Antiquarian, and Picturesque Tour in France and Germany* (1821); *The Library Companion* (1824); *Bibliophobia* (1832); *Reminiscences of a Literary Life* (1836); and *Bibliographical, Antiquarian, and Picturesque Tour in the Northern Counties of England and Scotland* (1838). All Dibdin's books are valuable and interesting, but whimsical and flippant in style, and unhappily abounding in errors. Dr Dibdin was one of the founders of the 'Roxburgh Club' (1812).

**Dibranchiata.** See CEPHALOPODA.

**Dice** (plural of die), small cubes of ivory marked on their sides with black dots, from one to six. The *points* on the opposite sides of the dice should always sum seven—i.e. ace should be opposite to six (pronounced *six*); deuce to cinque (pronounced *sink*); and trey to quatre (pronounced *later*). Two dice are called a *pair*.

By 13 Geo. II. chap. 19, 'all games invented or to be invented with one or more die or dice' were prohibited, except backgammon and games played on a backgammon board. Hence hazard is illegal, and also raffles with dice, the latter being also forbidden as lotteries even if dice are not used. By 9 Geo. IV. chap. 18 (1828), a duty of twenty shillings was imposed on every *pair* of dice; in 1862 the duty was abolished.

The invention of dice is attributed to Palamedes (circa 1244 B.C.). But the use of cubes with numbered sides for gambling purposes is probably much earlier. See HAZARD.

**Dicentra**, a genus of Fumariaceæ, of which one species, the 'Chinese lantern plant,' *D. spectabilis* (described by Linnaeus in 1753, but only introduced from Asiatic into British flower-gardens in

*Dicentra spectabilis*.

1846), has become a universal favourite on account of its long racemes of drooping, delicate, rosy-pink flowers. In America it is commonly known as 'Bleeding Heart.' It is a herbaceous perennial of

easy propagation. There are several other North American species, one of which *D. formosa* is a favourite and very showy garden-plant. Owing, in the first instance, to a misprint, *Dicentra* has been as frequently called *Dielytra*, the original mistake having become consecrated by habit.

**Dicey**, ALBERT VENN (1835-1922), English jurist, spent his early years at Claybrook, near Lutterworth, and was educated in London and at Balliol College, Oxford. Called to the bar in 1863, he soon gained a reputation as a student of the constitution. He was Vinerian Professor of Common Law at Oxford from 1882 till his retirement in 1909. His chief books, classics in their sphere, are *Law of the Constitution* (1885), *Conflict of Laws* (1896), *Law and Public Opinion in England* (1905). See his *Memorials*, ed. Rait (1925).

**Dichlamydeus**, a term in botany applied by De Candolle to distinguish those dicotyledonous flowers possessed of both calyx and corolla from his *Monochlamydeæ*, in which not more than one floral envelope is present.

**Dichogamy.** See FLOWER (*Fertilisation*).

**Dichotomy** (Gr., 'divided into two equal parts'), a term formerly vaguely used in botanical description to designate any appearance of branching by forking. Thus the stems of some phanerogams—e.g. mistletoe, dum palm, and many inflorescences—e.g. Caryophyllaceæ, Begonias—appear forked, while an ordinary fern-frond has no such appearance. The progress of morphological research has, however, shown that true dichotomy—i.e. complete division of the growing point into two lateral apices, is really as characteristic of the development of the fern-frond as of such obviously dichotomous vegetation as that of *Selaginella*; while conversely the appearance of forking in phanerogams comes about simply by the suppression of the growing point, and the development of two new axes from opposite lateral buds. Outside the cryptogams, indeed, no case of true dichotomy has been described, except perhaps the roots of cycads.

**Dichroism** (Gr. *dis*, 'twice,' *chrōma*, 'a colour') is a term chiefly used in Crystallography to designate the property which many doubly-refracting crystals possess of exhibiting different colours when viewed in different directions. It, or the allied term *Dichromatism*, has also been applied to those fluids which appear of different colours when viewed by reflected and refracted light; when seen in thick or thin layers, &c. For example, venous blood, or any blood impregnated with carbonic acid, hydrogen, or nitrogen, appears, when seen in moderately thin layers, to be of a purple colour; while in extremely thin layers it appears green.—For *Dichroite*, see CORDIERITE.

**Dick**, JAMES (1743-1828) a West Indian and London merchant, who was born at Forres, Morayshire, and left over £113,000 to promote higher learning among the parish schoolmasters of Elgin, Banff, and Aberdeen shires.

**Dick**, SIR ROBERT, major-general, was born at Tulliemet, in Perthshire, about 1785, fought in Sicily and Egypt, held a command at Busaco, Torres Vedras, Ciudad Rodrigo, Salamanca, and Burgos, at Quatre Bras and Waterloo, and fell heading the assault at Sobraon, 10th February 1846.

**Dick**, ROBERT (1811-66), a self-taught geologist and botanist, born at Tullibody, Clackmannanshire, was from 1830 a baker in Thurso.

**Dick**, THOMAS, a popular religious and scientific writer, was born 24th November 1774, near Dundee. At a very early age he became devoted to the study of astronomy, and at twenty went to the university of Edinburgh with a view to the ministry in the Secession Church. Licensed in 1801, he preached

some time; next kept school for ten years at Methven, and for ten years more at Perth. Meantime he laboured laudably to promote popular education by 'Literary and Philosophical Societies' corresponding closely to the Mechanics' Institutes of later days. His first book was *The Christian Philosopher* (1823), which quickly became popular. Its success led Dick to devote himself to astronomy and literary work in a cottage near Broughty-Ferry, where he set up an observatory. His many books brought him great popularity both in England and America, but very little pecuniary return. In 1847 he received a crown pension of £50, supplemented by a local subscription. He died at Broughty-Ferry, 29th July 1857. His degree of LL.D. was given him by Union College, New York. Other works were *Celestial Scenery* (1837), *The Sidereal Heavens* (1840), and *The Practical Astronomer* (1845).

**Dickens, CHARLES**, was born at Landport, now a great town, but then a little suburb of Portsmouth or Portsea, lying half a mile outside of the town walls. The date of his birth was Friday, February 7, 1812. His father was John Dickens, a clerk in the navy pay-office, and at that time attached to Portsmouth dockyard. The familiarity which the novelist shows with seaports and sailors is not, however, due to his birthplace, because his father, in the year 1814, was recalled to London, and in 1816 went to Chatham. They still show the room in the dockyard where the elder Dickens worked, and where his son often came to visit him. The family lived in Ordnance Place, Chatham, and the boy was sent to a school kept in Gibraltar Place, New Road, by one William Giles. As a child he is said to have been a great reader, and very early began to attempt original writing. In 1821, Charles being then nine years of age, the family fell into trouble; reforms in the Admiralty deprived the father of his post and the greater part of his income. They had to leave Chatham and removed to London, where a mean house in a shabby street of Camden Town received them. But not for long. The unfortunate father was presently arrested for debt and consigned to the Marshalsea, and Charles, then only ten years of age, and small for his age, was placed in a blacking-factory at Hungerford Market, where all he could do was to put the labels on the blacking-bottles, with half a dozen rough and rude boys. The degradation and misery of this occupation sunk deep into the boy's soul. He could never bear to speak of this time; it was never mentioned in his presence. Not only were his days passed in this wretched work, but the child was left entirely to himself at night, when he made his way home from Hungerford Market to Camden Town, a distance of four miles, to his lonely bedroom. On Sundays he visited his father in the prison. Of course such a neglected way of living could not continue. They presently found a lodging for him in Lant Street, close to the Marshalsea, where at least he was near his parents, and his father shortly afterwards recovering his liberty, they all went back to Camden Town, and the boy was sent to school again. It was to a private school in the Hampstead Road, where he remained for three or four years of quiet work. It must have been then, one suspects, rather than at Chatham, that he became so great a devourer of books. But he was never a scholar in any sense, and the books that he read were novels and plays. That the family fortunes were still low is proved by the fact that when he was taken from school no better place could be found for him than a stool at the desk of a solicitor. Meantime his father had obtained a post as reporter for the *Morning Herald*, and Charles, feeling small love for the hopeless drudgery of a lawyer's office, resolved also to attempt

the profession of journalist. He taught himself shorthand with the resolution—even the rage—which he always threw into everything he undertook; and he frequented the British Museum daily in order to supplement some of the shortcomings of his reading. In his seventeenth year he became a reporter at Doctors' Commons. At this period all his ambitions were for the stage. He would be an actor. All his life, indeed, he loved acting and the theatre above all things. As an actor one feels certain that he would have succeeded. He would have made an excellent comedian. Fortunately, he was saved for better work.

It was not until he was two-and-twenty that he succeeded in getting permanent employment on the staff of a London paper as a reporter. In this capacity he was sent about the country to do work which is now mainly supplied by local reporters. It must be remembered that there were as yet no railways. He had to travel by stagecoach, by post, by any means that offered. 'I have been upset,' he said years afterwards, speaking of this time, 'in almost every description of vehicle used in this country.'

About this time he began the real work of his life. In December 1833 the *Monthly Magazine* published his first original paper, called 'A Dinner at Poplar Walk.' Other papers followed, but produced nothing for the contributor except the gratification of seeing them in print, because the magazine could not afford to pay for anything. However, they did the writer the best service possible, in enabling him to prove his power, and he presently made an arrangement with the editor of the *Evening Chronicle* to contribute papers and sketches regularly, continuing to act as reporter for the *Morning Chronicle*, and getting his salary increased from five guineas to seven guineas a week. To be making an income of nearly four hundred pounds a year at the age of two or three and twenty, would be considered fortunate in any line of life. At that time such an income represented a much more solid success than would now be the case. The sketches were collected and published in the beginning of the year 1836, the author receiving a hundred and fifty pounds for the copyright. He afterwards bought it back for eleven times that amount. In the last week of March in the same year appeared the first number of the *Pickwick Papers*; three days afterwards Dickens married the daughter of his friend George Hogarth, editor of the *Evening Chronicle*; and his early struggles were finished.

No article, however short, treating of Charles Dickens, can avoid entering into the details of his early history with a fullness which would be out of all proportion to what follows, but for the remarkable fact that the events of his childhood and his youth impressed his imagination and influenced the whole of his literary career so profoundly, that to the very end of his life there is not a single work in which some of the characters, some of the places, are not derived from his early recollections. Many other writers there are who have passed their childish days among the *petites gens*, but none who have so remembered their ways, their speech, and their modes of thought. The Marshalsea prison of *Little Dorrit* is the place where for two years he went in and out. The Queen's Bench and its Rules were close to the Marshalsea; Bob Sawyer's lodgings in Lant Street were his own; David Copperfield, the friendless lad in the dingy warehouse, was himself; the cathedral of Edwin Drood was that in whose shadow he had lived; Mrs Pipchin is his old landlady of Camden Town; the most delightful features in Mr Micawber are borrowed from his own father; the experiences of Doctors' Commons, the solicitors' clerks, the

life in chambers, are all his own; while of individual characters the list of those which are known to be portraits more or less true to nature might be indefinitely extended. And yet, while he was always drawing on these early recollections, while they constantly furnished him with scenes and characters, he could not bear to speak of them, and no one except his friend and biographer, Forster, ever knew that he was, himself, with all the shabby, mean surroundings in early life, exactly such as David Copperfield.

The rest of Dickens's life has the interest which belongs to success after success. It was a long triumphal march. He had no failures; he suffered no defeats. There were times when his hand was not at its best, but never a time when his hand lost its power. This indeed seems the crowning happiness of a successful and singularly happy life, that when he was cut off—he died 9th June 1870—after fifty-eight years of continuous work, his brain was still as vigorous, his eye as keen, his hand as sure as in the first fresh running of his youth. It was indeed more than literary success which he achieved; he conquered the whole English-speaking world. This world, which now numbers one hundred and sixty millions, loves him; all who can read his books love him, and shall continue to love him. This love cheered him in his life, and will keep his memory green. Of the solid wealth which he acquired, the honour he enjoyed, the friends who gathered round him, and the brave and resolute front which he always showed, there is no space here to speak.

The following is the list of Dickens's works in their order of appearance, omitting certain farces and pamphlets which belong to a more extended notice: *Sketches by Boz* (1836), *The Posthumous Papers of the Pickwick Club* (1837), *Oliver Twist* (1838), *Nicholas Nickleby* (1839), *The Old Curiosity Shop* (1840-41), *Barnaby Rudge* (1841), *American Notes* (1842), *Martin Chuzzlewit* (1843), *The Christmas Tales*—viz. A Christmas Carol, The Chimes, The Cricket on the Hearth, The Battle of Life, The Haunted Man, and The Ghost's Bargain (1843, 1846, and 1848); *Pictures from Italy* (1845), *Dombey and Son* (1846-48), *David Copperfield* (1849-50), *Bleak House* (1852-53), *The Child's History of England* (1854), *Hard Times* (1854), *Little Dorrit* (1855-57), *A Tale of Two Cities* (1859), *The Uncommercial Traveller* (1861), the Christmas numbers in *Household Words* and *All the Year Round*, *Great Expectations* (1860-61), *Our Mutual Friend* (1864-65), *The Mystery of Edwin Drood* (unfinished). This long roll by no means represents the whole work of this most active of mankind. Public readings both in this country and in America, private theatricals, speeches, letters innumerable, journeys many, pamphlets, plays, the conduct of a popular magazine—first called *Household Words* and then *All the Year Round*—and an ever-present readiness to enjoy the society of his friends, fill up the space when he was not actually writing. That he could do so much was mainly due to his orderly and methodical habits, to his clearness of mind, and to a capacity for business as wonderful as his genius for fiction. He knew no rest from the day when he first attacked shorthand to the day when he fell from his chair in the fit from which he never recovered. He was incomparably the most active man, the hardest-working man of his age. In the history of letters there are many who have produced more work in bulk; there is not one who led a life so varied, so full, so constantly busy, so active and so rich.

It is as yet too early to speak with certainty as to the lasting popularity of his work as a whole. Very much of it owed its general success to the faithful delineation of manners already passed away.

He was the prophet of the middle class, and the manners of that great section of the community have greatly changed since the days when Charles Dickens lived among them and observed them. With the decay of these manners some part of present popularity must certainly pass out of his work: already a generation has appeared to whom a great deal of Dickens's work proves of no interest, because it portrays manners with which they are not familiar. They do not laugh with those who laughed fifty, forty, twenty years ago, because the people depicted have vanished. But when the second quarter of this century shall belong so truly to the past, that not one survives who can remember it, then these books will become a precious storehouse for the study and the recovery of part, and that a large part, of its life and manners.

Again, it is the essential quality of genius to create the type. In this Dickens has been more successful than any other novelist, ancient or modern. With him every leading character stands for his class. Squeers is the representative of the schoolmaster, then too common, ignorant, brutal, and grasping; Winkle is the Cockney sportsman; it is impossible to think of red tape without naming Mr Tite Barnacle; and so on through all the books. If he sometimes too plainly labels his characters with their qualities and defects, it is a fault caused by his own clearness of conception and of execution. It is another note of genius to suffer every character to work out its own fate without weakness or pity, and though Dickens deals seldom with the greater tragedies of the world in his domestic dramas, necessity pursues his characters as grimly and certainly as in real life. The villain Quilp and his tool make us forget, in the amusement which they cause, their own baseness. But their creator is not deceived. He makes them bring their own ruin upon their heads. To be true, not only to the outward presentment and speech and thought of a character, but also to the laws which surround him, and to the consequences of his actions, is a rare thing indeed with those who practise the art of fiction. Further, in this art there are permissible certain exaggerations, as upon the stage. There is exaggeration of feature, exaggeration of talk, exaggeration of action. There are degrees of exaggeration, by which one passes through tragedy, comedy, farce, and burlesque; but in all there must be exaggeration. Dickens was master of exaggeration—if he sometimes carried it too far, he produced farce, but never burlesque. As for selection, which is perhaps the most important point after exaggeration, it came to him by instinct; he knew from the very outset how to select. It is by selection that the novelist maintains the interest of his story and develops his characters. There are countless things that are said and done in the progress of the history which have little interest and small bearing on the things which have to be told; and it is the first mark of the bad novelist that he does not know how to suppress irrelevant scenes. In the constructive branch of his art Dickens continually advanced. His earlier stories seem, like the *Pickwick Papers*, to be made up of scenes. *Nicholas Nickleby* is a long series of scenes brilliantly drawn, in which new characters are always appearing and playing their disconnected part and disappearing. But as he grew older his conception of the story itself grew clearer, and his arrangement more artistic. It is however in description that Dickens proved himself so great a master. He laid his hand by instinct upon the salient and characteristic features, and he never failed in finding the right—the only—words fit for their illustration. In description he is never conventional, always real, and yet he allows himself, here as in his scenes of character and dialogue, a certain

exaggeration which produces the happiest effects. In the hands of his imitators it becomes grotesque and intolerable.

As to his great and splendid gallery of portraits it is difficult to speak briefly. The whole of London life—the life of the streets, of the city, of the middle class—seems at first sight depicted in this gallery. Here are merchant, shopkeeper, and clerk, lawyer and client, moneylender and victim, dress-maker, actor—one knows not what. Yet there are great omissions. The scholar, the divine, the statesman, the country gentleman are absent, partly because Dickens had no knowledge of them, and partly because he forebore to hold them up to the ridicule which he loved to pour over his characters. His methods imposed upon him certain limitations; he aimed at commanding his readers' attention by compelling laughter and tears, but especially laughter. He who can command neither the one nor the other is no true artist in fiction. But in his laughter and in his tears one feels always the kindly heart as well as the skilful hand. It is for the former—for the deeply human heart—even more than for the latter that the world will continue to love the memory of Charles Dickens.

See his *Letters*, ed. his daughter (1880-82); his *Life* by Forster (1871-74); books by Sir A. W. Ward (1882), Marzials (1887), F. G. Kitton (1889-1905), Fitzgerald (1903), T. Shore (1905), Chesterton (1906), Dibels (1920); Sir A. Quiller-Couch (1925); *The Childhood of Dickens*, by Langton (1891); his *Letters to Walkie Collins* (1892); *My Father as I Recall Him*, by Miss Mamie Dickens (1897); and the study by G. Gissing (1898). See articles CRUIKSHANK, BROWNE (HABLOT K.).

**Dickinson, EMILY** (1830-86), was born at Amherst, Mass., where she spent all her days. A strict recluse, she yet found 'ecstasy in living,' absorbed in the world of the mind and the soul. Introspection led to verse-writing, and with no thought of publication, she accumulated little poems which were not issued till after her death (3 series: 1890-96). Later volumes edited by her niece appeared in 1914 and 1925. Tense, terse, delicate, vivid in imagery, her work proved a beacon of growing brightness to poets of the century that followed her own.

**Diclinous**, a Linnean term for flowers possessing stamens or pistils only—*Monœci*, *Diœcia*, and *Polygamia*.

**Dicotyledons**, one of the two great divisions of the Angiosperms (q.v.), the other being the Monocotyledons. Probably the latter are derived from the dicotyledonous order Polycarpiceæ, which includes Nymphæaceæ, Magnoliaceæ, Calycanthaceæ, Ranunculaceæ, Lauraceæ, &c. The embryo of dicotyledons possesses, with rare exception (usually due to parasitic degeneration—e.g. Dodder, q.v.)—two cotyledons facing each other, and more or less embracing the plumule, while there is generally less endosperm than in monocotyledons, and, in fact, it is frequently absorbed altogether (see OVULE, SEED). The cotyledons usually develop equally, but one may be arrested.

The fibro-vascular bundles of dicotyledons are open and collateral, with few exceptions arranged in a reticulated cylinder, which thus presents a single circle in transverse section. The parenchyma in which they lie is thus divided into two main regions—the cortical layer or cellular envelope, and the pith; while the intermediate spokes of parenchymatous tissue connecting the pith and cortex through the meshes of the cylinder are the medullary rays. While the fibro-vascular bundles of dicotyledons arise like those of cryptogams and monocotyledons, by the differentiation into wood and bast of a special strand of primitive embryonic tissue continuous with that of the growing point, they differ in a marked

tendency to embryonic persistence of a central layer of this as the Cambium (q.v.), and hence in so many groups of dicotyledons there arises that association of perennial habit and continuous growth of stem to which we owe our familiar shrubs and trees. See PHYSIOLOGY (VEGETABLE), WOOD, BARK, BAST. Since the cambium lies between the wood and bast, the new layers of wood are external to the older ones, but those of bast internal to their predecessors: hence Lindley's name *exogens* was apt to be misleading. The softness and delicacy of the cambium layer leads, when force is applied, to the easy separation of the bast elements of the bundles, along with the cortical parenchyma and epidermic layer, as the *bark*.

The reticulated character of the bundles of the stem is similarly present in the Leaf (q.v.), which thus presents a marked contrast to the usually parallel venation of the monocotyledons. It also shows far greater variety of form and adaptation.

The flower has most frequently its parts arranged in whorls of five, although four is also a not uncommon number; hence another very obvious distinction from monocotyledons, in which a timorous symmetry prevails. The outer perianth whorl is most frequently green, as a calyx. See FLOWER, PHANEROGAMS, and VEGETABLE KINGDOM; also ANGIOSPERMS, and MONOCOTYLEDONS.

**Di'cranum**, a genus of mosses, of which some are among the commoner British forms. See MOSSES.

**Dictean Cave**, on Lasithi, in Crete, the birthplace of Zeus, was excavated by Dr Hogarth in 1900.

**Dictamnus**. See DITTANY.

**Dicta'tor**, in the earliest times, was the name of the highest magistrate of the Latin Confederation, and in some of the Latin towns the title was continued long after these towns were subjected to the dominion of Rome. In the Roman Republic the dictator was an extraordinary magistrate, irresponsible and endowed with absolute authority, whose original name was *magister populi*. The frequency of crises, or critical periods, in the quick, aggressive growth of the Roman state, necessitated such an office. The first dictator (T. Larcus or M. Valerius) was appointed 501 B.C., nine years after the expulsion of the Tarquins. According to Livy, the immediate cause of this dictatorship was a formidable war with the Latins. In general, no one could be appointed dictator who had not been previously consul, and this condition was very rarely dispensed with. Niebuhr was of opinion that the dictator was originally created or elected by the curia, like the kings, but it is more probable that the senate passed a decree ordering one of the consuls to name or proclaim (*dicere*) a dictator. Originally, of course, the dictator was a patrician; the first plebeian who filled the office being C. Marcus Rutilius, 356 B.C., who was nominated by the plebeian consul M. Popilius Lænas. The dictatorship could not *lawfully* be held longer than six months, nor was it ever so, except in the cases of Sulla and Cæsar, which were altogether peculiar. It must not be supposed that during a dictatorship the functions of the other magistrates were positively suspended. The consuls and other regular authorities continued to discharge their proper duties, but in subordination to the dictator; being for the time simply his officers. The superiority of his power, when compared with that of the consuls, appears chiefly in these three points: he was far more independent of the senate; he had a more extensive power of punishment, without any appeal; and he could not be called to account after his abdication of the dictatorship for anything he had done during the period of his office. The

*limits* of his power were as follows: he could not touch the treasury; he could not leave Italy; and he could not ride through Rome on horseback without previously obtaining the permission of the people. While the consuls had only twelve lictors, the dictator was preceded by twenty-four, bearing the *secures* and *fascēs*. To him also belonged the *sella curulis* and the *toga praetexta*. The last legally elected dictator was M. Junius Pera, who entered on his office 216 B.C. From this time *nominal* dictators were frequently appointed for the purpose of holding the elections, but even these finally disappeared 202 B.C. See HORSE (MASTER OF); and for modern dictators, FRANCIA and ROSAS.

DICTATORSHIP OF THE PROLETARIAT is a phrase used by Marx in a letter of May 1875. 'Between capitalist and communist society,' he says, 'lies the period of the revolutionary transformation of the one into the other. This requires a political transition stage, which can be nothing else than the revolutionary dictatorship of the proletariat.' This has been variously interpreted. The Russian Bolsheviks and those who agree with them take it to mean a mode of government by force to be adopted by a ruling proletarian party from the time of its gaining political power to the time, at least, when a socialist economic and social system is fully established. By this government democracy is suspended, and suffrage, freedom of the press and of organisation and the like, are to be denied to opposition, even to socialist opposition. Socialist opponents hold that social revolution must adapt its pace to the advance of socialism among the majority, and cannot otherwise be made permanent.

**Dictionary** (late Lat. *dictionary*), a book containing the words of a language alphabetically arranged, with their definitions and significations set forth more or less fully, and often their etymologies and illustrative quotations from literature.

Dictionaries may be divided into two classes—(1) those whose object is to explain words and phrases; and (2) those that aim at giving information about things.

(1) Dictionaries of language are, again, divided into various sub-classes or species. The most common kind—what, indeed, is understood by the term dictionary (and the equivalent Greek term *Lexicon*) when used by itself—is an alphabetical list of the words composing any language either explained in the same language, or interpreted by the corresponding words of one or more other languages. To indicate that all the words of the language are included, the name *Thesaurus* ('Treasury') is sometimes used, as in the great Hebrew dictionary of Gesenius. The words used by particular authors or classes of authors are often explained in *special* dictionaries or lexicons, such as those to Livy, Cicero, Tacitus, Homer, Sophocles, Shakespeare, and the like. A *Glossary* is a dictionary of unusual terms, as archaic, provincial, or technical terms. An *etymological* dictionary is one in which the derivation of words is the sole or a prominent object.

(2) Dictionaries of things (Ger. *Realwörterbücher*), or of information, are also of various kinds. When the whole field of human knowledge is embraced, we have an alphabetical Encyclopedia or Konversations-Lexikon. The name Encyclopedia or Cyclopaedia is sometimes given to dictionaries of special departments of knowledge, as *Anatomy and Physiology*; but in all such cases dictionary seems the correcter term, as in the well-known dictionaries edited by Sir William Smith, which cover the whole ground of Bible terms, Greek and Roman biography and mythology and antiquities, Christian antiquities, and Christian biography.

There is no kind of information, within wide or

narrow bounds, that may not be thrown into the dictionary form. Dictionaries of apt quotations from the classics, the Scriptures, or the fathers were not unknown in the 17th century. There are dictionaries of biography, of geography, of music, of gardening, of dates, of architecture, of cookery, of political economy, of heraldry, of fortification—in fact, of every object of human knowledge and practice.

Dictionaries of language, in our sense of the word, are of modern origin. The Greeks and Romans had no idea of a book embracing all the words of their own or any foreign tongue. Glossaries, however, of unusual words and phrases were early current. The earliest work of the kind extant (though much interpolated) is the Homeric Lexicon (Gr. *Lexicon Homērikon*) of Apollonius, an Alexandrine grammarian of the time of Augustus. Compilations, such as the Lexicon of Suidas (q.v.), and the *Etymologicum Magnum* (see ETYMOLOGY) were made in the middle ages. A real dictionary became first possible after the invention of printing. A broad and sure basis for Greek lexicography was laid by Henry Stephens (q.v.) in his *Thesaurus* (1572), on which the school of Hemsterhuis built further, and which has been greatly extended by the labours of Schneider, Passow, Seiler, Jakobitz, Rost, and Pape. The well-known work of Liddell and Scott (8th ed. 1897) is based on the great German one of Passow. The *Thesaurus* (1531) of Robert Stephens inaugurated Latin lexicography, which has been extended by Joh. Matth. Gesner, Forcellini, Ducange (medieval Latin), Scheller, Freund, Georges, Muhlmann, and Vaniček, and is well represented in English by Riddell and White, Andrews, Smith, and the Americans Lewis and Short. The earliest standard dictionaries of modern tongues were the Italian *Vocabolario della Crusca* (1612); the Dictionary of the French Academy (1694; new ed. 1878 *et seq.*); and that of the Academy at Madrid (1726–39). The great German Dictionary, begun in 1854 by the brothers Grimm, is still unfinished. Littre's French Dictionary (4 vols. and supplement) appeared in 1863–78. The materials collected by the Philological Society formed the main foundation for the great New English Dictionary, edited by Sir J. A. H. Murray, Dr Henry Bradley, Professor W. A. Craigie, and Mr. C. T. Onions, with much assistance from outside. This splendid work follows a strictly historical method, and aims to give all the significations of every English word during the last seven hundred years, with a series of quotations illustrating its usage. English dictionary-making in its larger sense began with Dr Johnson (q.v.), the basis of whose work was an interleaved copy of Nathan Bailey's Dictionary (1721–27).

See for Scots words, Jamieson (1808–25; ed. Donaldson, 1879–87); for etymology, Wedgwood, Edw. Müller (German), Skeat, and Weekley. The great *English Dialect Dictionary* (6 vols. 1898–1905, ed. Jos. Wright) supersedes Halliwell, T. Wright, &c. For older English words, the chief are Elfric's *Glossary* (about 975), Way's edition (1843–65) of the *Promptorium Parvulorum* (about 1440), Bosworth's *Anglo-Saxon Dictionary* (ed. Toller), Sweet's *Student's Anglo-Saxon Dictionary*, Stratmann's *Middle-English Dictionary* (ed. H. Bradley, 1891), Grein's *Sprachschatz der Angelsächsischen Dichter*, and Mätzner's *Altenglische Sprachproben*, &c.; as well also the English words in Cotgrave's *French-English Dictionary* (1611), Minshew's *Guide into Tongues* (1617), &c.—See BIOGRAPHY, ENCYCLOPEDIA, and articles on the various languages; also Vater's bibliography of dictionaries; Murray's *English Lexicography* (1900); and Lindsay, *The Corpus, Epinal and Erfurt Glossaries* (1921).

**Dictynna**, a Cretan nymph, known also as Britomartis and as Aphaia. Pursued by Minos, she leapt into the sea, and became the patron goddess of fishermen.

**Dictys of Crete**, a follower of Idomeneus in the Trojan war, whose name is attached to a professed journal of the leading events of the contest, which has come down to us in Latin prose, under the title *Ephemeris Belli Trojani*. An introduction relates how the narrative, inscribed in Phœnician characters on bark-paper, was found in a coffer of tin in Dictys's tomb, which had been burst open by an earthquake in the reign of Nero, and how the emperor caused it to be translated into Greek; this is accompanied by a letter from one Quintus Septimius, who claims to have prepared the condensed Latin version that follows. This dates probably from the 4th century A.D., and though of no intrinsic value, was a chief source of the romances of the middle ages. The best editions are those of Dederich (Bonn, 1832 and 1837) and Meister (Leip. 1872). See TROY; DUNGER, *Dictys-Septimius* (1878); FARRER, *Literary Forgeries* (1907); and GRIFFIN, *Dares and Dictys* (1907).

**Dicuil**, Irish geographer, wrote in 825 *De Mensura Orbis Terræ* (ed. Parthey, Berlin, 1870), and a lost treatise on grammar.

**Dicyemidæ**, a family of very lowly multicellular organisms, parasitic in habit. They are found in cuttle-fishes, while related organisms known as Onchocnecida occur in a brittle-star and in a Nemertean worm. Professor E. van Beneden has included them all under the title Mesozoa in contrast to the lower (single-celled) Protozoa on the one hand, and the higher (many-celled) Metazoa on the other. The largest species of the genus *Dicyema* measures 5-7 millimetres; the smallest is ten times less. These organisms hardly rise above the level of the embryonic gastrula, and some seem hardly to attain it, but it is still uncertain how much of this simplicity is primitive, and how much the result of degeneration. See E. van Beneden and C. Julin, *Archives de Biologie* (1882); Whitman, *Mitth. Zool. Stat. Neapel* (1883); Braun, *Bronn's Thierreich*, vol. iv.

**Dicynodon**, an important type of Triassic reptile, usually included in the order Anomodontia. They have been unearthed in Africa, India, and the Ural region, and more recently remains have been found in the Elgin Trias of Scotland—e.g. *Gordonia* and *Geikia*. They seem to have been purely terrestrial animals, and exhibit a most interesting combination of reptilian and mammalian characters. See REPTILE.

**Didache**. See APOSTLES (TEACHING OF THE TWELVE).

**Didactic Poetry**, that kind of poetry which aims, or seems to aim, at instruction as its object, making pleasure entirely subservient thereto. It has been disputed whether or not the existence of a kind of poetry especially entitled to the name didactic is consistent with the very nature and object of the poetic art. For it is held that, to point out instruction as the peculiar object of one kind of poetry, is to overlook the high aim of all poetry; and that a poem may be in the highest sense didactic, which yet is epic, dramatic, or lyric in its form; and the Book of Job, the Psalms, and other poems contained in the Sacred Scriptures, are quoted as examples. In the poems generally called didactic, the information or instruction given in verse is accompanied with poetic reflections, illustrations, and episodes. The *Georgics* of Virgil has been the model for most didactic poems, and no subject is so unpromising that it has not found some one to select it as a poetic theme. Examples of admirable success as combinations of argument and poetry are the *Ars Poetica* of Horace and the *Essay on Criticism* of Pope. The great poem of Lucretius, again, stands the masterpiece of the philosophical poem, which is represented in our

own language by poems like the *Nosce Teipsum* of Sir John Davies, and the *Essay on Man* of Pope. See POETRY.

**Didelphia**. See MARSUPIALS.

**Didelphis**. See OPOSSUM.

**Diderot**, DENIS, was born on October 15, 1713, at Langres, in Champagne, where his family had for two centuries been engaged in the manufacture of cutlery. An eldest son, he was intended for the church, and received his early training at the Jesuit school in his birthplace. After studying at the Collège d'Harcourt in Paris, he offended his father by refusing to become either a lawyer or a physician, and was in consequence flung upon his own resources. From 1734 until about 1744 he led a life of haphazard, ill-paid toil as a tutor and a bookseller's hack. In 1743 he married Annette Champion, a young sempstress, against the wishes of her friends, and without the knowledge of his family. After she had borne him a son, he persuaded his wife to remove with the child to Langres, where she brought about a reconciliation between Diderot and his father. His marriage, however, did not prove a happy one. During his wife's absence in Champagne he formed a liaison with a Madame Puisieux which lasted for several years; and later in life he became attached to a financier's daughter, Mademoiselle Voland, to whom he remained devoted until her death in 1774. His *Pensées Philosophiques* were burned by order of the Parliament of Paris in 1746, and three years afterwards he underwent imprisonment for the opinions expressed in his *Lettre sur les Aveugles*. His appointment to the editorship of an encyclopædia which the bookseller, Le Breton, had resolved upon publishing, assured him of a regular income, and gave him a commanding position in the world of letters. Le Breton's intention had been merely to issue an expanded version of the English *Cyclopædia* of Ephraim Chambers, which had appeared in 1727. But in Diderot's hands the character of the work was transformed. He enlisted nearly all the important French writers of the time as contributors, and in place of a storehouse of useful information, produced an engine of war for the *philosophe* party (see ENCYCLOPÆDIA). For some twenty years he stood at his post in spite of dangers and drawbacks, before which even a strong man might pardonably have flinched. The book was again and again threatened with prosecution; its sale was more than once prohibited; its editor ran a constant risk of imprisonment or exile. D'Alembert, at one time co-editor with Diderot, forsook him in despair at the obstacles to be overcome. But his marvellous energy, his varied knowledge, above all, his faculty of rallying and inspiring his fellow-workers, enabled Diderot to carry his vast undertaking to a successful conclusion. The first volume appeared in 1751; the last, in 1765. In his later years Diderot fell into pecuniary difficulties from which he was rescued by Catharine II. of Russia, who purchased his library, but allowed it to remain in Paris, and installed him at a salary as its caretaker. In 1773 he paid a visit to his benefactress, by whom he was most cordially received. He returned to Paris after spending five months in the palace of the empress at St Petersburg, and four months at the Hague as the guest of Prince Galitzin. During his old age he lived principally in his study at the corner of the Rue Taranne, spending his days in reading and meditation, in directing the studies of his daughter—the only survivor of his four children, in the giving of good counsel, and the doing of good works. He died from a stroke of apoplexy on the 30th July 1784.

One of the most prolific and versatile, Diderot was also one of the most careless of writers. He

worked in almost every department of literature. He was a novelist and a dramatist, a satirist, a philosopher, a critic of pictures and books; while as a letter-writer he was surpassed by none of his contemporaries. His published works are far from embodying the results of his labours as an author. He was ever ready to contribute without reward, often without acknowledgment, to the writings of others; he has been well termed the munificent prodigal of letters. His efforts in fiction include a story in the manner of Crébillon, described by Carlyle as 'the beastliest of all past, present, or future dull novels'; *La Religieuse*, a powerful story written with the object of exposing the evils of conventual life; and *Jacques le Fataliste*, a collection of short tales of which some are good and others indifferent, while one of them is a little masterpiece. *Le Neveu de Rameau*, an imaginary conversation between the author and a parasite of the great, is probably the strongest as it is the most curious of all Diderot's works. In the course of this dialogue, which was translated by Goethe, the follies and corruptions of society are laid bare with sardonic humour and piercing insight. Diderot's plays were somewhat unsuccessful examples of what was then known as *tragedie bourgeoise*, or of what we should now term melodrama. His happiest dramatic efforts were two short pieces which were never acted, *La Pièce et le Prologue* and *Est-il Bon? Est-il Méchant?* The letters which he addressed to Mademoiselle Voland, and which were first published some fifty years after his death, form the most interesting section of his voluminous correspondence. They give an entertaining and wonderfully vivid picture of the life that was led in the Baron d'Holbach's country-house at Grandval, the headquarters of the most advanced members of the *philosophe* party. As a critic Diderot stood far in advance of his contemporaries, and anticipated the Romanticists in advocating a return to nature and in seeking to free the drama from the trammels which had been imposed on it by the classical school. His criticisms bear the marks of over-hasty production, but their originality, shrewdness, and abounding vivacity more than atone for the lack of literary finish. His *Salons*, remarks on pictures exhibited at different times in Paris, are the earliest example of aesthetic criticism in modern literature. His philosophical works include *Pensées Philosophiques*, *La Promenade du Septième*, *Lettres sur les Sourds et Muets*, *Lettre sur les Aveugles*, *Le Rêve de D'Alembert*, *Essai sur la Vie de Sénèque*, *L'Interprétation de la Nature*, and a long criticism on Helvétius's treatise *De l'Homme*. Diderot has been frequently described as an atheist; whether justly or not is a matter very hard to decide. He was at one time deeply influenced by the naturalistic religion of Shaftesbury, and that writer's influence upon his mind was never wholly effaced. In certain passages he appears to write as a pantheist. But he never set forth his philosophy in consistent and systematic form.

Diderot is so unequal a writer that his works must be read in the mass before a just estimate can be formed of his extraordinary gifts. His keenest sayings, his most pregnant thoughts, are frequently imbedded in dullness. An indefatigable worker, he yet never took his work seriously enough. He lacked the faculty of concentration and the artist's mastering sense of form. His prose is not sustained at a high level of excellence; he sins grievously against good taste; his thoughts are not seldom crude and shallow; his mannerisms—notably his abuse of apostrophe—his 'sensibility' and his *philosophe* cant are not a little trying to the reader. But with all their defects his writings are wonderfully alive—fertile in original ideas—racy with a stimu-

lating flavour which is all their own; abounding in careless felicities of phrase and in sayings which flash a new light into human nature; rich with the sap of a humour which resembles the humour of no other Frenchman, and which Carlyle has likened to the humour of Cervantes. Inferior to Voltaire and Rousseau as a literary craftsman, he was a deeper thinker than either; his knowledge of men was profound, and his learning was truly encyclopædic. Ardent and generous, though lacking in self-restraint, he was one of the best of friends and the most charming of companions. In the opinion of his contemporaries his powers as a conversationalist eclipsed his gifts as a writer. He appears to have possessed an unrivalled faculty of improvisation; to judge from the testimony of shrewd critics who listened to him, his talk was as pointed and pregnant in its substance as captivating in its eloquence. 'He who knows Diderot only in his writings,' said Marmontel, 'does not know him at all.'

The most complete edition of his works is that by Assézat and Tournoux (20 vols. 1875-77). See the study by Rosenkranz (Leip. 1866); Lord Morley's *Diderot and the Encyclopædists* (2 vols. 1878); E. Scherer's study (1880); Sainte-Beuve's *Portraits Littéraires*, Carlyle's *Miscellanées*; and French monographs by Reinach (1894), Colignon (1895), Ducros (1895, 1900), and Tournoux (1899).

**Dido**, or ELISSA, the legendary founder of Carthage, was the daughter of the Tyrian king Belus or Agenor, and the sister of his successor, Pygmalion. Pygmalion murdered her husband and uncle, Sicharbas or Zacharbaal, a priest of Hercules. With the treasures which Pygmalion had sought for in vain, and accompanied by many Tyrians, Dido escaped to sea. She landed in Africa, not far from the Phœnician colony of Utica, and built a citadel called Byrsa (Gr. *Bursa*, 'the hide of a bull'), on a piece of ground which she had bought from the Numidian king Iarbas. The meaning of the word Byrsa gave rise to the legend that Dido purchased as much land as could be encompassed with a bullock's hide. Once the agreement was concluded, she cut the hide into small thongs, and thus inclosed a large piece of ground, on which she built the city of Carthage. To avoid being compelled to marry Iarbas, she stabbed herself on a funeral pile, which she had caused to be erected, and after her death was honoured as a deity by her subjects. Virgil ascribes the death of Dido to her unrequited passion for Aneas; but many of the ancient writers conceived that the poet had committed an anachronism in making her contemporary with the Trojan prince. In the common chronology, more than three hundred years separated the fall of Troy (1184 B.C.) from the founding of Carthage (853).

**Didot**, the name of a celebrated family of French printers and publishers.—FRANÇOIS DIDOT (1689-1757) was the first of the family that attained eminence. His principal professional achievement was the publication of the *Voyages* of his friend the Abbé Prévost, a work in 20 volumes, perfect as regards the text, and enriched with a great number of engravings. Two of his sons, FRANÇOIS AMBROISE (1730-1804) and PIERRE FRANÇOIS (1732-1795), also acquired distinction as printers, the former publishing editions of the *Delphin* classics, while the latter improved the typefounding and paper-making arts.—HENRI (1765-1852), eldest son of Pierre François, made himself famous as an engraver and letter-founder, producing very beautiful 'microscopic' types.—PIERRE, eldest son of François Ambroise (1760-1853), still further increased the fame of the family. His Louvre editions of Virgil, Horace, Racine, and La Fontaine are magnificent; and he it was who published Boileau's works and Voltaire's *Henriade*.

He was himself an author.—His brother, **FIRMIN** (1764–1836), as a printer, and especially as an engraver and founder, raised the family name to the pinnacle of professional eminence. The perfect Roman characters, used in the Louvre editions printed by his elder brother, were engraved and cast by him. He revived and developed the stereotyping process, and produced singularly perfect editions of many classical, French, and English works. He became a deputy, and obtained some reputation as an author by his tragedies, *La Reine de Portugal* and *La Mort d'Annibal*, and several volumes of metrical translations from the classics.—Firmin's sons, **AMBROISE FIRMIN** (1790–1876) and **HYACINTHE FIRMIN** (1794–1880), aided by their sons, sustained the credit of the Paris house as Firmin Didot Frères.

**Didunculus.** See **SAMOA**.

**Didyma**, or **DIDYMOI**, 12½ miles SW. of Miletus, had a great temple of Apollo with an oracle.

**Didymium** is a very rare substance found in the minerals Cerite, Allanite, &c. It was supposed to be an element of atomic weight 142, and specific gravity 8.5. It is found associated with Cerium and Lanthanum, and as their salts have closely similar properties, their separation is very difficult. The supposed salts of didymium are generally soluble and rose-coloured. Auer von Welsbach showed didymium to be composed of at least two metals. Its constituents have been named neodymium (Nd) and praseodymium (Pr). The former, which preponderates, forms violet and pink, the latter green, salts. They are very much alike in their chemical properties. Their atomic weights are 144.3 and 140.6. Their spectra are characteristic.

**Diebitsch**, **JOHN CHARLES**, COUNT, a Russian field-marshal, was born in Silesia in 1785, and made the campaigns of 1805 and 1812–14. In the Turkish war of 1829 his forcing a passage of the Balkans (Kulevtscha, &c.) by dint of hard fighting was commemorated in the surname conferred on him of Sabalkanski ('crosser of the Balkans'). He died of cholera in February 1831, while endeavouring to suppress the insurrection in Poland.

**Diedenhofen.** See **THIONVILLE**.

**Diefenbach**, **LORENZ**, a great philologist, was born at Ostheim, in the grand-duchy of Hesse, 29th July 1806, studied theology and philosophy at Giessen, travelled much, and was twelve years pastor and librarian at Solms-Laubach. In 1848 he settled at Frankfurt-on-Main, where he was second city librarian 1863–76. He died at Daumstadt, 28th March 1883. His literary industry was enormous, embracing poetry and romances, as well as those more ponderous works by which his name will live. His greatest books—monuments of sagacity and learning—are *Celtica* (3 vols. 1839–40); *Vergleichendes Wörterbuch der Gotischen Sprache* (2 vols. 1846–51); *Glossarium Latino-Germanicum medicæ et infirmæ ætatis*, a supplement to Ducange's well-known Glossary (1857); *Origines Europææ*; *Hoch- und Niederdeutsches Wörterbuch* (with Wulcker, 2 vols. 1874–83).

**Diefenbach**, **JOHANN FRIEDRICH**, surgeon, was born at Königsberg, 1st February 1794, and in 1832 became extraordinary, in 1840 ordinary, professor of Surgery at Berlin, where he died, 11th November 1847. He was distinguished as an operator, especially in the art of forming by transplantation new noses and lips. He wrote several works of no great importance on surgery, being little more than a brilliant operator.

**Diego Garcia**, an island of the Indian Ocean, in 7° S. lat., and 72°–73° E. long., extends in an irregular horseshoe shape, and is 30 miles long, embracing between its extremities three minor

islets (the Chagos Islands). It contains a spacious bay, and exports coconut-oil. The group has about 500 inhabitants, and is a dependency of Mauritius.

**Diego Suarez**, the name of a fine bay at the north end of Madagascar (q.v.), ceded to France by treaty in 1885.

**Dielytra.** See **DICENTRA**.

**Diepenbeck**, **ABRAHAM VAN**, painter and draftsman, was born at Bois-le-Duc in 1607, or, according to other accounts, in 1596 or 1599. He studied under Rubens in Antwerp, and after a residence in Italy, returned to be an assistant of that painter. He first devoted himself to glass-painting; but he soon turned to oil-painting and designing. Examples of his work in oils are in Paris, Dresden, and Vienna. His plates to Marolles' *Tableaux du Temple des Muses* (1655), engraved by Cornelis Bloemaert, were much admired. He visited England in the reign of Charles I., where he painted some windows, and was much employed by the Duke of Newcastle, for whom he executed various portraits and views, and drew the plates for that nobleman's famous folio on Horsemanship (1657). These plates are valuable not only for their excellence, but for the number of portraits they contain. He was elected president of the Antwerp Academy in 1641, a post which he retained till his death in 1675.

**Dieppe**, a seaport in the French department of Seine-Inférieure, on the English Channel, 40 miles N. of Rouen by rail. It is situated among chalk cliffs, at the mouth of the river Arques, and is regularly built. It has a castle (1433), now occupied as barracks, commanding the town and the harbour, which has been recently extended. Dieppe has a college and a school of navigation, and there is a fine Gothic church of the 13th century, as well as a handsome bathing establishment and casino. Being one of the principal watering-places of France, the town has a great accession of visitors during the summer months. It manufactures clocks, lace, and tobacco; and its carved articles of horn, bone, and ivory have long been famous. There are also shipbuilding yards and distilleries; and the fisheries, which are important, employ almost the whole of the population of Pollet, one of the two suburbs of the town. In 1066 Duke William sailed from Dieppe to the conquest of England. It was then a mere village, but its importance steadily increased, until it reached the heyday of its prosperity in the period between the middle of the 14th century and the end of the 17th. Expeditions sailed hence for the west coast of Africa, where Petit Dieppe was founded at the mouth of the Gambia; and many of the early voyages to Canada were made from this port. A terrible bombardment by the English and Dutch, however, destroyed all but two or three buildings in 1694; and though rebuilt, the town never recovered its importance, and even before the rise of Havre had already sunk to a secondary port. Nevertheless, packets still ply regularly to New-haven. The town is a favourite landing-place of English tourists, and its import and export trade is chiefly with England and Norway. Pop. 24,000.

**Diesel**, **RUDOLF**, inventor of the Diesel oil-engine (see **INTERNAL-COMBUSTION ENGINE**), was born of German parents in Paris in 1858, studied at technical colleges in Augsburg and Munich, and managed engineering works in Paris. He disappeared from a steam-packet crossing from Antwerp to Harwich, 29th–30th September 1913.

**Die-sinking**, the art of engraving the die or stamp used for striking the impression on coin and medals, and for stamping thin plates of metal into various shapes. The method of sinking the dies used for coins or medals will serve to illustrate the

general method of die-sinking. Suppose the coin to be of the size of a shilling: a cylindrical piece of carefully selected steel, about three or four inches in length, and two in diameter, is prepared by slightly rounding one end of the cylinder, then turning and smoothing upon the middle of this a flat face equal to the size of the coin. This blank die, which is carefully softened by the process of Annealing (q.v.), is then engraved with the device of the coin in intaglio. This is a very delicate and artistic operation, and is effected by a great number of careful touches with small and very hard steel tools. The face of the die is now protected with a thin coating of lampblack and linseed-oil, and then placed with its face downwards in a crucible containing animal charcoal. In this position it is raised to a cherry-red heat, then taken out, and hardened by being plunged into water. When properly tempered, it is in a state to be used for stamping the coin; but dies of superior workmanship, from which many impressions are required, are not thus directly used, as the expense of engraving is very great, and the risk of breakage considerable. This first engraved die, called the matrix, is therefore reserved only for making other dies. An impression in relief is made from this matrix on a small block of soft steel, which is called the puncheon; this is retouched and hardened, and from it the dies directly used for striking the coins or medals are impressed. When the engraving is not very costly, a small number of impressions required, or a soft metal is to be stamped, as in livery buttons, for example, the work is stamped directly from the engraved die or matrix. See MINT.

Die-engraving is a very ancient art, and was perhaps first suggested by the closely allied art of engraving gems. Notwithstanding the great number of ancient Greek coins which have been preserved, very few of the many dies which were used for these have been found. The Greek coins struck between the years 415 and 336 B.C. show that the art of engraving dies had then reached the highest point of excellence which it ever attained either in ancient or modern times. As works of art, the Italian medals of the 15th and 16th centuries come next in merit to Greek coins, but none of these of the 15th, and only the smaller-sized ones of the 16th, century time were struck from dies. All the others were cast either from wax models or from patterns made in other materials. The art of cutting dies, in the comparatively deep intaglio required for medals, consequently dates from the beginning of the 16th century. Since then, or soon after it, Germany, France, Russia, and England, as well as Italy, have all had many more or less famous die-engravers.

The engraving of dies for medals is perhaps that branch of the art which gives the greatest scope for artistic skill, although the work on those required for coins is nearly identical in its character. Comparatively few dies of new design are, however, required for coins, while many hundreds of medal dies are annually made in England. The medals struck from these are used for such purposes as awards at exhibitions, colleges, and schools; for prizes at various games, and in commemoration of various events. Copper, bronze, and tin are the metals most commonly employed for medals, the copper being usually 'bronzed' on the surface. A copper medal with a head in moderately high relief requires half a dozen blows in the screw-press to bring up a sharp impression; but some in very bold relief require to be struck with as many as thirty blows. The medal requires to be frequently annealed during the process. Coins are finished at one blow, so that the devices upon them are only in slight relief. When a coin or a medal is being

struck, a steel collar, accurately fitted to the die, is used to prevent the metal from spreading.

Dies have been extensively applied to the manufacture of many kinds of objects in metal. These are of all sizes, from those required for parts of jewellery upwards. Large and heavy dies are, however, cast, and only in some cases finished with the graver. Dies for forgings are made by a machine which reproduces a model die. Dies have been used also in the stamping or pressing of solid pieces of wood into ornaments, in high relief, to imitate wood-carving. By the same process similar ornaments, in bas-relief, are made in pieces of wood formed of several layers of veneers.

**Dies Iræ**, the name generally given to the celebrated Latin hymn on the Last Judgment, from the first words of its first stanza:

Dies iræ, dies illa,  
Solvat sæculum in favilla,  
Teste David cum Sibylla.

This incomparable hymn consists of seventeen such stanzas, with an eighteenth of four lines, and is based on the prophetic passage, Zephaniah, i. 14-18. It is probably the work of the Franciscan, Thomas de Celano, who died about 1255. The sublimity and force of its thoughts are well matched with the impressive solemnity of the verse, its stanzas of three lines, each with the same double rhyme, making the inmost soul tremble, 'as with three blows of a hammer,' says Guericke. It is said to have first appeared in the missals made at Venice about 1250, and is one of the five 'Sequences' that have been universally used in the Roman Catholic Church since the Council of Trent. Its place is in the *Missa in commemoratione omnium fidelium defunctorum*. The Tridentine text, published in 1567, is somewhat different from that in the old missals, and another and considerably inferior version appears on a marble tablet of unknown date, in a Franciscan church at Mantua. The *Dies Iræ* has been the subject of musical compositions by Palestrina, Haydn, Cherubini, and Mozart, and no religious poem has been more frequently translated. There are English translations by Crashaw, Macaulay, Lord Lindsay, Isaac Williams, and others. The opening stanzas are paraphrased in the *Lay of the Last Minstrel*, canto vi.

See Julian's *Dictionary of Hymnology* (1892); 'Fifty Versions of the *Dies Iræ*' in the *Dublin Review* (1882); a list of ninety-two versions in the *Athenæum* (July 1890); and C. F. S. Warren, *The Dies Iræ* (1897).

**Diest**, a town and fortress of Belgium, in the province of Brabant, on the river Demer, 37 miles SE. of Antwerp by rail, with manufactures of woollen goods, beer, and gin. Pop. 8200.

**Diet**. The different classes of food-stuffs, and the value or potential of different foods, are described in the article FOOD. In the article DIGESTION the changes which the food undergoes in the alimentary canal are treated. It is here proposed to describe the quantity and quality of food which experience has shown to be required in order to preserve the body in health and vigour. Of course, no two individuals are alike, and the assumption will in the first place be made that an average healthy man of ordinary height and weight, and doing ordinary work, is alone under consideration.

In order to understand the requirements of the body in respect of food, it is necessary to bear in mind how complex the body is. Its chief activities are muscular and nervous, and not only have the brain and the muscular system to be fed, but in addition the various glands, cartilages, bones, and other tissues are all constantly requiring nourishment. If we examine all these tissues under the microscope, we see that although all are alike in some respects, yet that they differ one from another

considerably in others. Their work, too, is different; and we should expect, and experiment shows, that they require different food.

Just as the life of the whole body is the sum of the lives of the different parts (cells) of the body, so the food must contain that which is necessary for these parts. The body has frequently been compared to a steam-engine, but, as we have seen, the body is complex, and the comparison should rather be between it and a collection of steam-engines, each one differing from the other in its pattern, use, and the kind of fuel required to stoke it. A steam-engine requires a store of fuel (containing the potential-power), by the combustion of which it moves. It also requires its parts to be repaired, and sometimes a new boiler or piston is necessary. In addition, it requires other things, so that it may work well, such as oil, which is neither burned nor used to build up the machine. In the same way the body, and each part of it, requires first, a store of fuel, from the combustion of which its energy or activity is obtained; secondly, material by which its wasted parts may be repaired; and, thirdly, substances such as water, salt, &c., which are required by the body, but which are neither burned nor used entirely in forming tissue. The term 'food' may then be applied to all that the body requires from without; and following out our comparison, corresponds with the stoking, mending, and oiling of a number of steam-engines.

Let us consider in the first place the food, which, like the fuel for the engine, the body requires in order to manifest its own peculiar activities. The coal of an engine contains carbon and hydrogen, which become oxidised by the oxygen of the air. As a result of this oxidation, we have heat and mechanical motion. In like manner the body receives food containing large quantities of carbon and hydrogen. At the same time oxygen is absorbed by the blood as it passes through the lungs. The digested food and the oxygen are taken by the blood to the tissues—muscles, brain, &c.—and within these tissues a slow oxidation takes place, giving rise to the heat of the body as well as mechanical and other activities. Just as the steam-engine requires a sufficiency of coal, so the body requires a certain quantity of food. In both cases the supply of oxidisable material must have what may be termed a sufficient 'potential'—that is to say, it must have the power of producing a certain amount of heat and mechanical motion. Some coals and some foods burn better than others, and their potential in that case is greater. Fat among the food-stuffs has the greatest potential, carbohydrates and proteins have less. It is obvious, then, that one cannot speak of the body requiring a certain weight of food per diem. This would mean nothing, for the value of different food-stuffs varies considerably, a pound of one kind of food being equivalent in potential, say, to twenty pounds of another. In arranging a diet one must carefully consider not only the quantity of food given, but in addition one must calculate its potential. The steam-engine may be driven at full or at half power, and in the latter case the amount of fuel required will be diminished. In the same way an individual doing hard work requires food with more potential, or, as we say, more nutritious food, than another living an easy and uneventful life, and still more than one confined to the house or to his bed.

There is yet another important point to be considered. In a steam-engine the production of heat is not what is sought as a result of the combustion within the steam-engine; the engineer constructs the machine with a view to obtaining the result of the combustion not in heat, but in mechanical motion. In the best machines, one-tenth of the

potential is converted into work, while the rest, nine-tenths, is rejected into the atmosphere as heat. The human mechanism can convert as much as one-fifth of the potential of its food into work, and changes four-fifths into heat. In the case of the human machine, however, heat is very necessary, especially if the body be ill clothed or surrounded by a cold medium. The powerlessness of the hands when numbed with cold will illustrate the necessity of a requisite temperature. Warm clothing actually saves food. Not only is the temperature of the body maintained in a cold climate by preventing its conduction and radiation from the body by the use of warm clothing, but appetite prompts the consumption of a large quantity of food, and especially those kinds that contain great potential. The Eskimos devour great supplies of fat blubber, and they are even said to prefer the taste of rancid oil to that of the less combustible sugar.

It has been found by experiment that a man of average height and weight, well clothed, in a temperate climate, and doing a fair day's work, requires such quantity of food that the combustion of it, were it all converted into mechanical work, would raise 4000 tons one foot high, or, as it is expressed, 4000 foot-tons. This result has been arrived at by varying the diet until the minimum but sufficient quantity has been arrived at which will preserve the health and vigour. The potential of the diet can be calculated by an instrument called the calorimeter, which will give the heat produced during the burning of any combustible substance, and from the heat produced the potential in respect to mechanical work can be calculated. In the subjoined table the potentials of one ounce of each of three important food-stuffs are given:

	Foot-tons
Fats (beef fat) . . . . .	351.50
Proteins (albumen) . . . . .	105.2
Carbohydrates (starch) . . . . .	151.66

It will at once be seen how readily one could calculate the amount of food-stuff capable of furnishing the body with fuel for twenty-four hours. All that is necessary will be to divide 4000 by the number of foot-tons which correspond with the article selected; the quotient is the number of ounces required. Thus 11 ounces of fat, or 24 ounces of protein, or 26 ounces of starch would contain the necessary potential.

From what has already been said regarding the complexity of the bodily mechanism, it may be surmised that a single food-stuff (even if a quantity be taken which provides a sufficient potential) is incapable of stoking the body. Numerous experiments, such as those conducted by the Gelatine Commission, by Dr Hammond, and others, indicate that the body is unable to maintain its natural vigour on a diet consisting solely of gelatine, or of starch, or of protein, or of fat, &c. Animals fed on a single food-stuff waste rapidly, and will refuse their food after a few days with marked dislike, dying eventually of starvation. At least two staple articles of food must be given, mixed, even in this case, with many accessories, such as various salts, aromatic substances, &c., in order that health may be maintained.

Liebig taught that the muscular work of the body results from the oxidation of nitrogenous matter (protein, both animal and vegetable), but it is now known that all the classes of food-stuffs except the mineral matters are used by the muscles. Nevertheless proteins (nitrogenous food) are essential, as we shall see on experimental grounds, and from the fact that in the dietary of every nation protein matter is always present, combined at any rate with fat, generally with carbohydrates as well.

In many parts of the world man subsists with-

out the use of carbohydrates. The Eskimo and the North American Indian live entirely on the produce of the chase. The flesh of animals is rich in proteins and fats, but contains practically no carbohydrate. In the same way the Arab of the desert lives upon the flesh and milk of the camel, in districts where the date is not to be found. The use of carbohydrates is extensive in most temperate and tropical climates. Many of the inhabitants of India and Ceylon live chiefly on rice. Wheat, potatoes, and other vegetable foods, rich in carbohydrates, are staple articles of food both in Europe and America. In fact, within certain limits, man, like every other animal, is capable of adapting himself to the food produced by the district in which he lives. The French and Spanish peasants eat little meat, living on carbohydrates and vegetable proteins, and supplying necessary potential by an abundance of oil. The Sussex labourer consumes his beans, rich in vegetable proteins, and bacon, and does a good day's work on them. The Scottish labourer of a former generation lived on porridge and skimmed milk, with meat but once a week. The Arab of the Sahara, together with his family and his horse, subsists almost entirely on the date, while the Arab of the Nubian Desert hardly ever touches vegetable food. The diet of every man, under whatever circumstances, invariably contains proteins, although this may vary in its quantity. The universal use of protein matter in some form or other suggests its importance, and this is fully borne out by the evidence of direct experiment. If protein food be withdrawn from the diet altogether, nitrogenous matter continues to be eliminated from the body by the urine, although its supply is cut off. At the same time the body wastes, and death finally occurs. The experiments of Fick, Wislicenus, and Parkes show that during muscular exertion the body does not excrete any excess of nitrogen; and the writer's own researches show that urea—the most important excretion which contains nitrogen—is not found in abnormal extent in muscular tissue after exhaustive exercise. It would appear, therefore, that nitrogenous matter is not used by the tissues for fuel, and that when protein food is consumed, the muscles burn a non-nitrogenous substance which is formed from it. The nitrogen, in the form of urea, &c., is carried by the blood to the kidneys, and at once excreted. We must look elsewhere than in the ordinary combustion of a muscle or brain cell for a use for the nitrogen which, as we have seen, is so necessary an article of food in the form of a protein substance. In the child, the tissues which contain nitrogen in definite proportion are continually growing, and it will readily be seen that here, at any rate, we have an important use for protein diet—namely, to furnish the necessary nitrogen for the new tissue. Even during adult life we have tissue change and growth. The skin is continually growing in its deeper layers to replace its surface layers worn away by constant friction. In the same way the cells of the blood are always being broken down, and their places taken again by new ones continually forming. Although it is hardly probable that such complete changes take place in all the tissues of the body, yet, without the entire breaking down of individual cells, there are no doubt changes both integrating and disintegrating, which are constantly taking place. As a result of disintegrating changes nitrogenous matter in an effete form is being given off by the system, and it has to be replenished from without in a form which the body can use. The protein food-stuff provides nitrogenous pabulum for the tissues which they assimilate, and builds up new tissue material. For this reason protein matter is indispensable. At the same time the system obtains

from the protein food non-nitrogenous fuel to be burned by the tissues; this property of supplying tissue fuel is shared with the carbohydrate and fatty food-stuffs. It has been found by experiment that an ordinary diet should contain one part of nitrogenous matter (proteins) to about four of non-nitrogenous (fat and carbohydrates). If less nitrogenous matter be given, the tissue consumption of nitrogen will not be supplied, and the body will waste. If a much larger quantity of nitrogenous food be taken, a nitrogenous surfeit occurs, and the body is called upon to digest this excess, and to eliminate an unnecessary quantity of the useless nitrogenous compounds which result.

The following table from Dr Parkes shows the proper proportions of solid water-free food-stuffs in ounces required as daily food by an adult man:

	At Rest.	Ordinary Work.	Hard Work.
Proteins...	2.5	4.6	6 to 7
Fats .....	1	3	3.5 to 4.5
Carbohydrates.....	12	14.4	16 to 18
Total water-free food...	15.5	22.0	25.5 to 29.5

According to Professor Chittenden, who experimented with, amongst others, athletes and soldiers, we need only half the amount of protein suggested above. That is probably true, and is shown by the nature of the food amongst the Scottish and Irish peasantry of half a century ago, not to speak of the Hindu, the Chinese, and the Japanese. These people eat far less protein (meaty matter) than we do, and we must remember that owing to the increased cultivation of peas and beans, as well as the modern abundance of fresh meat, we eat far more protein than did our ancestors. We have got into the habit of eating too much protein, and we have to thank Professor Chittenden and the more moderate vegetarians for reminding us of this fact. It now becomes an easy matter to construct a diet table of articles of food. Most of these have been analysed.

TABLE FOR CALCULATING DIETS (Parkes).

Articles of Food.	Water.	Protein.	Fats	Carbohydrates	Salts.
Uncooked beef } and mutton..	75	15	8.4	..	1.6
Far pork.....	39	9.8	48.9	..	2.3
Dried bacon ..	15	8.8	73.3	..	2.9
Smoked ham....	27.8	24	36.5	..	10.1
White-fish.....	78	18.1	2.9	..	1.2
Poultry .....	74	21	3.8	..	1.2
White bread....	40	8	1.5	49.2	1.3
Wheat-flour....	15	11	2	70.3	1.7
Barley-meal....	11.8	12.7	2	71	3.0
Rye .....	13.5	13.1	2	69.3	2.1
Biscuits .....	8	15.6	1.3	73.4	1.7
Rice .....	10	5	.8	83.2	.5
Oatmeal .....	15	12.6	5.6	63	3
Maize .....	13.5	10	6.7	64.5	1.4
Macaroni .....	13.1	9	.3	76.8	.8
Arrowroot.....	15.4	.8	..	83.8	.27
Dry peas .....	15	22	2	53	2.4
Potatoes.....	74	2	.16	21	1
Carrots.....	85	1.6	.25	8.4	1
Cabbage .....	91	1.8	.5	5.8	.7
Butter .....	6	3.8	88	..	2.7
Eggs .....	73	13.5	11.6	..	1
Cheese .....	86.8	33.5	24.3	..	5.4
Milk .....	86.8	4	3.7	4.8	.7
Cream .....	66	2.7	26.7	2.8	1.8
Sugar .....	8	..	..	96.5	.5

Many articles of food owe their chief importance to their action as stimulants. Such are alcohol, tea, coffee, and beef-tea. Alcohol is no doubt burned within the body, and is a source of energy. Only a small quantity, however, can be so utilised, perhaps one ounce in every twenty-four hours in the case of an ordinary individual. As a source of energy, therefore, it is of little value, and such substances as fat, meat, bread, are capable of supplying the

potential at a very much smaller cost. Alcohol taken with other food stimulates the secretion of gastric juice, assisting in that way the digestive process. At the same time, however, the gastric juice is unable to act quite so readily upon the food, though this is hardly the case with diluted spirits, which form more wholesome beverages than strong wines or beer. No two individuals are the same, and while alcohol, in moderate doses, promotes digestion in most persons, others suffer from its use. See ALCOHOL (*Actions and Uses of Alcohol*). It should never be given in collapse and weakness without giving at the same time easily digested food when that is possible. It excites the body to great and often unnecessary activity, the potential for which it does not supply. Afterwards greater weakness ensues from want of the necessary fuel, which has not in the meanwhile been forthcoming. One should never drink without eating. Tea and coffee are both nervous stimulants, and at the same time they retard both gastric and salivary digestion.

Beef-tea is generally regarded as a food-stuff of high nutritive value. This is, however, not the case. It contains nothing besides salts and extractives, and has a very slight potential indeed. It has a stimulating effect, however, both on digestion and on the nervous system. From the mistaken ideas generally held as to the nutritive properties of this substance, thousands of invalids are annually starved to death (see BEEF-TEA). Beef-tea made by infusing the beef in *tepid* water is more nutritious, especially if the beef be finely minced and eaten as well.

In addition to the stimulants that we have already considered are many substances known as condiments, such as mustard, pepper, pickles, sauces. These are of utility in gratifying the palate, and in addition they probably stimulate the secretory juices. Sufficient information has not as yet been obtained as to their action on gastric and pancreatic digestion. They certainly stimulate the flow of saliva, although the acid condiments will prevent the perfect action of the salivary ferment.

Common salt is a condiment, and at the same time it plays many other important parts in the animal organism. So necessary is it that both man and animals suffer great hardships if it be not supplied in sufficient quantity. It is necessary for the formation of the gastric juice; it is present in the blood and in all tissues of the body.

Inorganic salts, such as sulphates, phosphates, are required for the formation of the skeleton, and salts of iron for the colouring matter of the blood. Organic salts, such as citrates and tartrates, are also of importance. That food should be easily digested is a matter of great importance. The rapidity of digestion will depend upon the amount and quality of the digestive juices, the kind of food, and the condition in which the food is eaten. Rice, tripe, whipped eggs, sago, tapioca, barley, milk, raw eggs, lamb, parsnips, potatoes, hashes of chicken, fish, are all easily digested substances. Beef, mutton, pork, roast fowls, bread, veal, oysters, are digested more slowly. Inasmuch as perfect digestion can only be accomplished when the digestive juices have acted for some time on all parts of the food taken, it follows that fine subdivision of food is very essential. On this account liquid food rapidly disappears from the stomach, which retains for a longer time solid masses upon which the gastric juice acts with greater difficulty. When food is cooked it swells, its fibres and solid particles are separated one from another, and it is more readily permeated by the gastric and pancreatic juices. In addition, starch becomes gelatinous, and in that form is easily digested by the

saliva and pancreatic juice. The diet of early infantile life differs from that of the adult, inasmuch as it should contain no starch. Milk, the natural food of the infant, is rich in fat, proteins, and a sugar called milk-sugar. There is in milk, however, an entire absence of starch, an article of food which the infant is destined to consume in such large quantities in later years. Moreover, during the first few months of its extra-uterine existence the child is unable to assimilate starch given with its food. On no account, therefore, must it be supplied with bread, potatoes, rice, or other vegetable food until the cutting of the teeth suggests a more solid diet. If the mother's milk be not in sufficient plenty, cow's milk diluted with one-third of water, with a pinch of sugar, may be given, or condensed milk diluted with twelve to twenty parts of water (see MILK). Condensed milk, owing probably to its very uniform composition, cannot be given alone for more than a few weeks together. It may, however, be given once or twice a day for months, and children thrive on it, when they in addition are supplied with good cow's, or still better, with their own mother's milk.

In conclusion, it may be well to consider the results which follow the neglect of the most obvious rules of dietetics. As the result of deficient food, one finds loss of muscular and nervous power, wasting of the tissues, and anæmia. If the deficiency be very great, feverish symptoms and great prostration result.

Many persons consume large quantities of food quite out of proportion to their size or activity. In this case, owing to a 'habit of digestion,' much of the food may pass through the digestive tract without being digested or assimilated. Under these circumstances the hearty eater is a wasteful eater, and is using for his own bodily needs only a fraction of the food he consumes. In addition, dyspepsia in various forms, constipation, and diarrhoea are apt to follow, indicating functional derangements of the digestive apparatus. There is often a tendency, especially in advanced years, to absorb more nourishment than is necessary for stoking the body and for replenishing ordinary tissue waste. The excess is stored up in the form of fat, which accumulates under the skin, chiefly under that of the abdomen. In addition, the muscles and internal organs are loaded with fat, the minute globules of which may be seen in the ultimate cells of which the tissues are composed. Hereditary tendency is well marked in cases of corpulency. In addition to corpulency, an excess of food is apt to engender various gastric troubles, engorgement of the liver, plethora, and an excess of effete extractions in the blood and urine. It is probable that humanity suffers more from an excess than from a deficiency of food. An excess of animal is more serious than an excess of vegetable food. The nitrogenous extractions, derived from the incomplete assimilation of meat, when present in large quantity, cause many symptoms, most of which are extremely obscure in their nature. These are provisionally spoken of as symptoms of gout. The ill effects which follow surfeit are more severe in those leading a sedentary and inactive life, bodily activity producing more efficient oxidation of the food taken. A healthy and abstemious man whose tastes have not been enslaved by the culinary art instinctively adapts his food to the requirements of his body. The cold of winter prompts the choice of substantial and energising food, while the heat of summer suggests a lighter dietary. After a country holiday, on returning to a sedentary life one at once reduces one's allowance of beef, or expects to pay the penalty that a disordered digestion is certain to exact. During the ages in which

humanity has been evolving, there has been a constant adaptation of taste and desire to the needs of the economy. The natural gustatory inclinations as a rule are a good indication of the bodily wants. As a rule wholesome things have a pleasant taste, and the reverse also holds good. It is all-important, however, that the satisfaction of mere gustatory pleasure be not allowed to monopolise too much of the energy of any individual. Under these circumstances a surfeit is certain to result. There is a well-known law in physiology to the effect that *greater and greater* stimuli have to be applied in order to produce a series of *equal* sensations. It follows that the excesses of the glutton and drunkard are out of all proportion to the actual pleasures these excesses produce, the wise man drinking and eating only in moderation. See COOKERY, FOOD, DIGESTION, INDIGESTION, VITAMINS.

**Diet**, a meeting of delegates or of dignitaries, held from day to day, for legislative or ecclesiastical purposes; the title was afterwards extended to such bodies themselves. The term is applied to the sessions of church assemblies in Scotland, and also to public worship, but its chief use is as the specific title of the assemblies of the German empire and some other Continental states (see GERMANY).

*Desertion of the Diet*, in Scots law. The proceedings under a criminal libel are in Scotland spoken of technically as a diet, and when the libel is abandoned by the public prosecutor, or where he fails to appear, he is said to desert the diet. The effect of a judgment of the court declaring that the diet has been deserted is to free the accused from prosecution under the particular libel or writ, but not to prevent a new process being raised on the same grounds.

**Diethylbarbituric Acid.** See VERONAL.

**Dietrich of Berne.** See THEODORIC.

**Dietz**, FEODOR (1813-70), historical painter, born at Neunstetten in Baden, died suddenly in France during the Franco-German war.

**Diez**, FRIEDRICH CHRISTIAN, the greatest of Romance philologists, was born at Giessen, 15th March 1794, and educated at Giessen and Göttingen, with one short interval in 1813 of campaigning as a volunteer. In April 1818 he saw Goethe at Jena, and was directed by the sage to the lectures of Raynouard and the study of the Provençal tongue. From 1822 he lived at Bonn as a *privat-docent*, and in 1830 was there appointed professor of the Romance Languages, and there he died, May 29, 1876. His first work, *Altspan. Romanzen* (1821), was followed by a series of valuable works on the Romance languages, of which the greatest are his *Grammatik der Romanischen Sprachen* (3 vols. 1836-38; 5th ed. 1882), and the *Etymologisches Wörterbuch der Romanischen Sprachen* (2 vols. 1853; 5th ed. by A. Scheler, 1887; Eng. trans. 1864). These works discussed these languages for the first time from the comparative historical standpoint, and thus formed a sound foundation for all subsequent Romance philology. See the books on Diez, his life and work, by Sachs (1878), Breymann (1878), and Stengel (1883-94).

**Difference**, CALCULUS OF FINITE DIFFERENCES Difference implies two quantities of the same kind, and means in arithmetic that quantity which must be added to the smaller in order to produce the larger, and in algebra that quantity which must be added to either to produce the other. Thus if the quantities be the numbers 5 and 7, their arithmetical difference is 2, while their algebraical difference may be either +2 or -2. The difference -2 arises from the fact that we may in algebra ask the question what must be

added to 7 to produce 5? and the answer to this is -2.

In certain groups of problems, chiefly relating to series, differences considered in a particular manner are of peculiar importance, constituting in fact a branch of higher algebra, which took its origin in Brook Taylor's *Methodus Incrementorum* (1715), and is now called the Method of Differences or the Calculus of Finite Differences. This method we shall briefly illustrate.

Suppose it were required to discover the law of formation, and thence to continue the series of numbers:

4, 3, 0, 1, 12, 39, 88, 165.

It would be wrong to assume that only one law of formation will produce these eight numbers, just as it would be wrong to assume that only one curve could be drawn through eight given points; but for the full discussion of the difficulty here raised the reader must be referred to the chapter on Interpolation in any text-book on the subject. We shall, however, show how to find one law of formation, and use our figures to illustrate the elementary notation of the subject. The process is to take the difference between each term and the succeeding one, and so get the first series of differences, or, as it is called, the series of first differences; the process is repeated on the first differences, and so on, as follows:

No. of term,	1	2	3	4	5	6	7	8
Given Series,	$u_1$	$u_2$	$u_3$	$u_4$	$u_5$	$u_6$	$u_7$	$u_8$
	4	3	0	1	12	39	88	165
1st Differences,	$\Delta u_1$	$\Delta u_2$	$\Delta u_3$	$\Delta u_4$	$\Delta u_5$	$\Delta u_6$	$\Delta u_7$	
	-1	-3	1	11	27	49	77	
2d Differences,	$\Delta^2 u_1$	$\Delta^2 u_2$	$\Delta^2 u_3$	$\Delta^2 u_4$	$\Delta^2 u_5$	$\Delta^2 u_6$	$\Delta^2 u_7$	
	-2	4	10	16	22	28		
3d Differences,	$\Delta^3 u_1$	$\Delta^3 u_2$	$\Delta^3 u_3$	$\Delta^3 u_4$	$\Delta^3 u_5$	$\Delta^3 u_6$	$\Delta^3 u_7$	
	6	6	6	6	6			

The line of third differences suggests a law of formation, and enables us to continue the series as follows:

	165	276	427	624
77	111	151	197	
28	34	40	46	
6	6	6	6	

It could further be shown that if  $u_x$  be the  $x$ th term of the series above, then

$$u_x = x^3 - 7x^2 + 13x - 3.$$

The operation indicated by  $\Delta$  is defined by the following equation, where  $u_x$  means any function of  $x$ :

$$\Delta u_x = u_{x+1} - u_x \quad (1)$$

or, if we denote the 1 added to  $x$  by  $\Delta x$ , by the equation

$$\frac{\Delta u_x}{\Delta x} = \frac{u_{x+\Delta x} - u_x}{1} \quad (2)$$

or with the appearance at least of greater generality by

$$\frac{\Delta u_x}{\Delta x} = \frac{u_{x+h} - u_x}{h} \quad (3)$$

As a final example let us suppose  $u_x = x^2$ . Then we have, using equation (1) above,

$$\Delta u_x = (x+1)^2 - x^2 = 2x+1$$

This is a case of the direct problem of the calculus, but there is also the inverse problem: Of what function is  $2x+1$  the difference? The solution to this is denoted by the symbols:

$$\Sigma(2x+1) = x^2,$$

or, strictly speaking, for reasons which we need not give, by

$$\Sigma(2x+1) = x^2 + C;$$

and  $x^2 + C$  is said to be the *integrate* of  $2x+1$ .

Between the Calculus of Finite Differences and the Differential Calculus (see CALCULUS) (a title which means the calculus of infinitesimal differences) there are many important points of contrast and of similarity, which would be not less clearly appreciated if the names were changed, as Boole all but suggested, the former to Calculus of Differences, the latter to Calculus of Limits.

The methods of the Calculus of Differences are in vogue among actuaries and others in dealing with statistics such as mortality tables; and from this calculus are derived many formulae of approximation of great practical value, such as the rules for finding the area of surfaces bounded by curved lines.

**Differentiation**, that organic progress which occurs when certain parts of a uniform whole become structurally different from the others, or when, in other words, the homogeneous becomes heterogeneous. Inequality in internal and external conditions of life brings about restriction of certain vital processes and the predominance of others, and as this division of function is established, diversity of structure results. Differentiation is the structural change which is associated with the physiological 'division of labour,' and the process is essentially the same whether it find expression in cells, tissues, organs, or entire organisms. See DIVISION OF LABOUR, EVOLUTION, VARIATION, &c.

**Diffraction**. In general, light is propagated in straight lines in a homogeneous medium; but, if it be caused to pass through an opening which is not large in comparison with the wave-length of the light, the law no longer holds. Such phenomena are said to be due to *diffraction*. This is further dealt with at INTERFERENCE and SPECTRUM.

**Diffusion**. The particles of all material bodies, except such as may be totally devoid of heat, are in rapid motion. In the case of solid bodies the excursions of any one particle are very limited; but in fluids a particle may move more or less freely throughout the whole space occupied. This intermixture of molecules may occur also when different fluids are placed in contact with each other, but it may be prevented by the existence of tension at the common surface (see SURFACE-TENSION and CAPILLARITY). When it does occur, the fluids are said to *diffuse* into each other. Diffusion has been observed in solids.

**Diffusion of Liquids**.—The diffusion of dissolved salts may obviously be considered under this heading. The phenomenon may be conveniently studied by introducing a strong solution of some highly-coloured salt, such as bichromate of potash, into the bottom of a tall glass cylinder nearly filled with water. The rate of diffusion varies with the nature of the liquids. Graham was the first to investigate the subject carefully. He filled a number of similar glass vessels with solutions of different salts. The mouths of these vessels were carefully ground so that they could be closed by means of glass plates. The different vessels were then placed in equal glass jars, and covered with water to a definite extent. Next the glass covers were cautiously withdrawn, and the diffusion was allowed to go on for a certain time. The rate at which each liquid diffused was thus obtained. Graham found that, for any one solution, the rate is proportional to the gradient of concentration—i.e. to the rate at which the quantity of salt dissolved per unit-volume varies per unit-length. Thus the law regulating diffusion of liquids is analogous to that which regulates the conduction of heat in a homogeneous solid. Hence the equations obtained by Fourier in his *Théorie de la Chaleur* apply to the problem under consideration.

Graham found also that rise of temperature

greatly increases the effect. He divided substances into two classes, *Colloids* and *Crystalloids*, the members of the first class diffusing very much more slowly than those of the second. His investigations have been much extended by more recent observers employing various methods of observation.

If two miscible liquids be separated by a membrane of bladder or of parchment paper, &c., diffusion takes place through the septum at rates which are usually very different for different liquids. This phenomenon is known as *Osmose* (q.v.). It was first shown by Nollet that, if a vessel filled with alcohol be closed by a piece of bladder and placed in water, the diffusion of the water is so much more rapid than that of the alcohol that the bladder is burst because of the increase of the contents of the vessel which it closes. By this means the various constituents of a mixture of colloid and crystalloid substances may be separated to any desired extent. The rate at which liquids diffuse into each other through a septum depends greatly upon the molecular action between them and the septum.

**Diffusion of Gases**.—If two flasks, each filled with a different gas at a given pressure and temperature, be placed in communication with each other, the gases will be found to interdiffuse. The rate of interdiffusion is shown by theory to be nearly in inverse proportion to the square root of the product of the densities of the two gases, and the experimental results are in accordance with the theory.

**Effusion of Gases**.—This is exhibited in the passage of a gas into vacuum under constant pressure through a small opening in a very thin plate otherwise impervious to it. The work done in the passage of a given volume of the gas is proportional to the pressure, and the equivalent kinetic energy is proportional to the product of the density and the square of the speed of effusion. Hence the speed for a given pressure varies inversely as the square root of the density. Graham showed that this result of theory is closely realised by experiment. He showed, further, that when a discrepancy exists, it is due to the finite thickness of the plate.

**Transpiration of Gases** is the term for the passage of gases under pressure through a fine capillary tube. This subject was also investigated by Graham, who found that the rate of passage is not affected by the material of the tube. This seems to indicate that the tube becomes coated internally with a thin film of gas, so that the opposition to the flow of gas is due to Viscosity (q.v.).

The rates at which different gases pass through fine unglazed earthenware are inversely as the square roots of their densities. Hence we have a means of separating gases the densities of which are different (see ATMOLYSIS). If the septum be made of caoutchouc, which is not porous, the passage of gases still occurs. The gas seems to combine with the matter of the septum on the one side, to diffuse through it, and finally to be given off on the other side. The passage of some gases, such as carbonic oxide, through hot cast-iron is analogous.

**Digamma** (literally 'double gamma') is the name given by the grammarians of the 1st century to the sixth letter,  $\Phi$  (see the article on  $\Phi$ ), of the early Greek alphabet, from its shape, which was that of a gamma,  $\Gamma$ , with the horizontal stroke doubled. The sound represented by this letter, approximately that of the English *w*, had disappeared from all Greek dialects some centuries before the Christian era; thus the original *woida*, I know, *newos*, new, are represented in classical Greek by *oida*, *neos*. The letter, in its proper

shape, was therefore known to the grammarians only from old inscriptions; but a corrupt form of it,  $\epsilon$ , was retained in the alphabet to serve as the numeral for 6, and, as this character had come to resemble the ligature for *st*, it received in this application the names *stau* and *stigmè*. The metre of the Homeric poems, as Bentley was the first to prove, indicates that they, or, at least, the oldest portions of them, were composed while the sound still existed in the language. The lists of words originally containing the digamma, given by Bentley and other scholars of a former day, were based partly on the testimony of ancient grammarians, and partly on the evidence of the metre of Homer and other poets; but comparative philology has now made it possible to determine with certainty (in most cases) whether any particular Greek word had originally this consonant or not. The letter, as used in modern works treating historically of the Greek language, is commonly printed  $\epsilon$ .

**Digby**, SIR KENELM (1603-65), was born at Gayhurst, near Newport Pagnell, son of Sir Everard Digby (1578-1606), who turned Catholic, and was hanged for his part in the Gunpowder Plot (q.v.). Kenelm himself was bred a Catholic, but in 1618, after a half-year in Spain, entered Gloucester Hall, Oxford (now Worcester College). He left it in 1620 without a degree, and spent nearly three years abroad, in Florence chiefly. At Madrid he fell in with Prince Charles, and following him back to England, was knighted, and entered his service. In 1625, after a singular courtship, he secretly married 'that celebrated beautie and courtezane, Venetia Stanley (1600-33), who had been his playmate in childhood. With two privaters in 1628 he vanquished a French and Venetian squadron off Scanderoon. On his wife's death he passed two hermit-like years, diverting himself with chemistry at Gresham College. In 1636 he announced his reconversion; and his tortuous conduct thereafter was dictated, it seems, by his zeal for Catholicism. He was imprisoned by the Parliament (1642-43), and had his estate confiscated; was at Rome (1645-47), where he finished by 'hectoring at his Holiness'; and thrice revisited England (1649-51-54), the third time staying two years, and entering into close relations with Cromwell. At the Restoration, however, he was well received, and retained his office of chancellor to Queen Henrietta Maria. He was one of the first members of the Royal Society (1663).

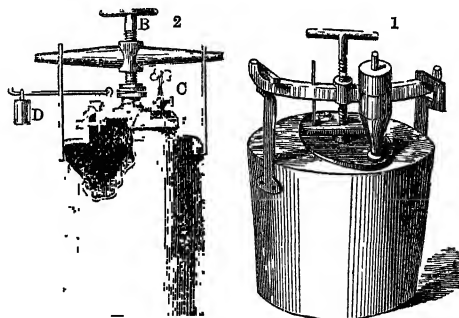

'The very Pliny of our age for lying,' said Stubbes of Digby, whom Evelyn terms 'an arrant mountebank.' Yet he was a friend of Descartes and Sir Thomas Browne; he could appreciate the discoveries of Harvey, Bacon, and Galileo. Sir Sidney Lee points out, that 'as a philosopher—an Aristotelian—Sir Kenelm undoubtedly owed much to Thomas White; and he questions whether his much-vaunted 'powder of sympathy' was not really invented by Sir Gilbert Talbot. Digby said he got the secret from a travelled Carmelite; and the specific was made of 'powder of vitriol' (copperas or some other sulphate), and was applied to a bandage, not to the wound. Digby's Discourse thereon (1658), like his *Treatise of Bodies and of Man's Soul* (1644), contains much that is curious, if little of real value. His *Discourse concerning the Vegetation of Plants* (1660) is the chief of his other twelve works.

See his bombastic *Memoirs*, dealing with his courtship (ed. Nicolas 1827); his *Scanderoon Voyage* (Camden Society, 1868); the Life of him 'by one of his descendants,' Le T. Longueville (1896); and H. M. Digby's *Sir Kenelm Digby and George Digby, Earl of Bristol* (his cousin, 1913).

**Digby**, KENELM HENRY, was born in 1800, youngest son of the dean of Clonfert. Having entered Trinity College, Cambridge, he took his B.A. in 1819, and three years later published the *Broad Stone of Honour*—'that noble manual for gentlemen,' as Julius Hare called it, 'that volume which, had I a son, I would place in his hands, charging him, though such admonition would be needless, to love it next to his Bible.' It was much altered and enlarged in the 1828 and subsequent editions (the latest 1877), its author having in the meantime turned Catholic. He died in London, where most of his long life was spent, on 22d March 1880. Of fourteen other works (32 vols. 1831-74) all the last eight were poetry.

**Digest**, a name often given to the Pandects (see JUSTINIAN) of the Roman law, because they contained 'Legalia præcepta excellenter digesta.'

**Digester**, PAPIN'S, is a strong boiler with a closely fitting cover, in which articles of food may be boiled at a higher temperature than 212° (100° C.). As its name implies, it was invented by Papin (q.v.), and a common form is the *Autoclave*, fig. 1, where the lid can be turned round under clamps or ears, and thus be rendered steam-tight. Another form is given in fig. 2, where a portion of the side

Papin's Digester.

is removed to exhibit the interior. The lid, A, is fastened down by a screw, B, and the steam generated in the boiler is allowed to escape at a stop-cock, C, or by raising the weighted valve, D. The increased pressure to which the contents of the boiler are exposed causes the boiling-point of the water to rise to 400° (204° C.), and occasionally higher. The digester is of great value as a means of preparing soups of various kinds, and especially in the extraction of gelatin from bones.

**Digestion** is the change which food undergoes in order to prepare it for the nutrition of the animal frame, and is carried on in the higher animals in the DIGESTIVE SYSTEM. In some of the lowest forms of animal life (amœbæ) particles of food may be drawn into the body (which possesses no special organs at any part of its surface), and may then be digested. In higher organisms, however, parts have become evolved, which serve more especially the function of digestion. Thus in the common sea anemone there is a simple pouch which leads inwards from the centre of the cluster of tentacles. Into this fish and other food are drawn and digested, while the undigested parts are afterwards voided through the same aperture by which they entered. In still higher organisms, man himself included, this simple pouch is changed into a complex and greatly elongated tube, which is provided with one aperture (the mouth) by which food enters, and another aperture (the anus) through which undigested matter leaves the body. The whole digestive system is lined with a soft mem-

brane, which is richly supplied with blood-vessels. This membrane is called the mucous membrane, and from it is secreted by the glands which it contains a viscid substance called mucus. If the finger be thrust into the back of the mouth, and the mucous membrane gently scraped, the fluid which will adhere to the finger is seen to be viscid: it is secreted by the glands of the mouth. Not only mucus, but many other substances useful in digestion are formed by little glands in the mucous membrane, so that the whole digestive system is bathed during digestion with fluid having a digestive action on the food. In addition there are other glands, such as the salivary, the liver, and the pancreas, which we may look upon as glands of the mucous membrane which have enormously developed. To so great an extent have they increased in size that they have got far outside the digestive system, and have become situated in neighbouring parts of the body, only connected with the digestive system by their ducts or elongated mouths.

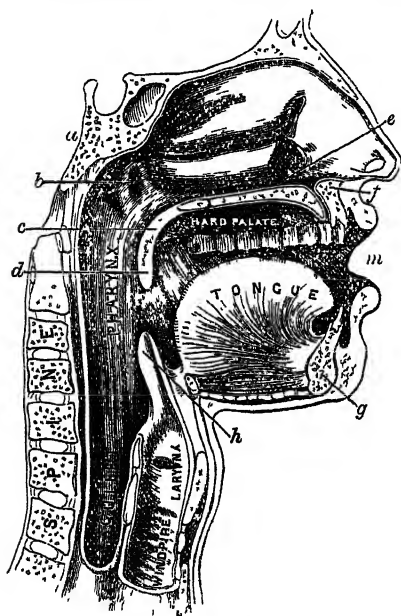

Fig. 1.—Section through Mouth, Nose, &c. :

*a*, sphenoid bone; *b*, Eustachian tube; *c*, soft palate; *d*, uvula; *e*, nasal passage; *f*, upper jaw; *g*, lower jaw; *h*, epiglottis; *m*, mouth.

Through these ducts their secretions, like that of the microscopic mucous gland, pour into the cavity of the digestive system. Outside the mucous coat we have the muscular coat, the function of which is to move the food onwards in its course, and to mix it with the digestive juices. In the mouth, throat, and the upper part of the gullet, the muscles which move the food onwards, as in swallowing, are, when examined by the microscope, seen to be transversely striped, and like other striped muscles their contraction is rapid. In other parts of the digestive system, however, the muscular coat consists of smooth muscle, and like all other smooth muscles this coat contracts slowly. On this account the food rapidly swallowed passes very slowly along the rest of the digestive system.

Having shown that the digestive system is a muscular tube, we may now consider it more in detail. The mouth (fig 1, *m*) is lined with mucous membrane, and into it is poured the secretion of three pairs of salivary glands—the parotids, situ-

ated in front of the ear; the submaxillary, within the angle of the lower jaw; and the sublingual, under the tongue. The mouth in most animals is provided with hard tissues—teeth, beaks—for the subdivision of food before it is swallowed. Vegetable feeders, eating tough grains, roots, and fibres, have large molar or grinding teeth, while the carnivora have these same teeth modified so as to present a cutting edge, with which and their pointed canines meat is torn and cut into pieces, which are then swallowed (see **TEETH**). The mucous membrane of the mouth is covered externally by the muscles of the cheek and lips. Into its cavity the muscular tongue projects. On looking into the mouth with a looking-glass, one sees back into the throat. The entrance to the throat will be observed to be bounded at the sides by two muscular curtains passing downwards obliquely to the sides of the root of the tongue. These are termed the anterior pillars of the fauces, and behind them, one on each side, are masses of lymphoid tissue, subject to enlargement, called the tonsils. Above, another curtain hangs down. It is called the soft palate, and separates the mouth from the hinder part of the nasal cavity. Projecting from its centre is a little cone called the uvula (fig. 1). The cavity of the pharynx, or the interior of the throat, is another cavity lined by mucous membrane, with muscular walls. These muscles constrict it (constrictors). Below, the cavity passes into the gullet or oesophagus, and in front of this tube runs the windpipe which communicates with the pharynx through the larynx, or organ of voice. Food will pass through the pharynx into the gullet; and air, during inspiration, passes through the pharynx on into the larynx and windpipe; a valve, called the epiglottis, partly closes the aperture of the larynx. The pharynx is common, therefore, both to the digestive system and the respiratory passages. Above, the pharynx communicates, as before described, with the mouth and also with the nose. One can demonstrate this latter fact by drawing smoke into the mouth, and expelling it by the nostrils. This communication is closed during the act of swallowing, and also during the singing of pure vowel-sounds, such as *ā*, *ō*, *ū*, and the closure is effected chiefly by the elevation of the soft palate, which acts as a valve. The pharynx communicates in addition with the mid-

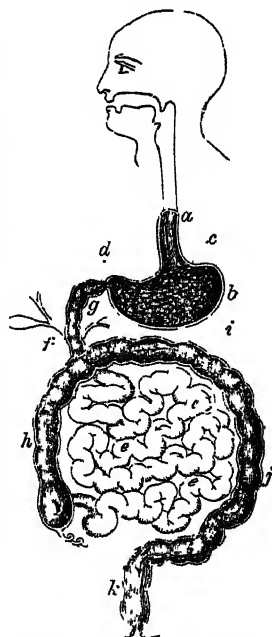

Fig. 2.—Human Alimentary Canal :

dle ear by the Eustachian tubes, and this may be rendered evident if the mouth and nose be closed, and a violent expiratory effort made at the same time. As the pressure of air within the throat is increased, the Eustachian tubes which

previously were collapsed now become distended, and a little wave of air at high pressure is forced into the middle ear, causing a buzzing sound. Occasionally the middle ear communicates with the external air through congenital or acquired apertures in the membrana tympani. In these cases smoke may be propelled from the throat out of one or both ears.

The gullet or oesophagus (figs. 1, 2, and 3) is a long tube passing from the pharynx to the stomach. Its mucous coat is loaded with very large mucous glands, which secrete a quantity of very viscid mucus. Its muscular walls contain striped fibres in the upper, unstriped in the lower part. The stomach itself is a greatly dilated part of the digestive system. Its shape is indicated in the fig. It may be said to consist of two parts, even in the human subject; a more complex arrangement is found in many animals, such as the ruminants. The large dilated portion into which the gullet opens is termed *cardiac*, and the opening the cardiac or oesophageal opening. The narrow part opening into the duodenum is the pyloric part, and the opening the pyloric opening. The whole is lined with mucous membrane, which, in the empty stomach, is thrown into projecting folds or rugae, but these folds are effaced when the organ is distended with food (fig. 3). In the

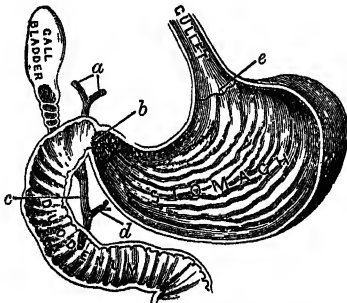

Fig. 3.—Section of the Stomach :

membrane are innumerable glands, which secrete the digestive juices of the stomach (fig. 4). If the surface of the membrane be examined with a strong pocket-lens, the apertures of these little glands may be seen. They run down from the surface into the deeper parts of the mucous membrane. They are lined by secreting cells. The greater number of glands situated in mucous membranes have the simple structure diagrammatically represented in fig. 4. Each gland has a mouth or short duct lined by cells. Below this the little tube is lined by cells which secrete the juice peculiar to the gland. This secreting part sometimes branches. Outside the gland blood-capillaries ramify, which supply the gland with nourishment, enabling it to manufacture the substances which it secretes. The gastric juice is acid, and the chief acid secreted is hydrochloric acid. This is formed at the cardiac, but not at the pyloric end. The substance called *pepsine*, which is necessary for digestion, is secreted by the whole of the glands. The cardiac glands therefore secrete both substances, and they possess two sorts of cells, those which form the hydrochloric acid being bigger and more granular than the other sort which secrete pepsine. The pyloric glands secreting pepsine have only one kind of cell similar to the pepsine-secreting cell of the cardiac end. Outside the vascular and glandular mucous coat, and united to it by a loose delicate

layer—submucous coat—is the muscular coat. This is similar to that of the rest of the alimentary canal, except that there are in addition to the circular and longitudinal fibres, many oblique fibres. The circular fibres are very thick indeed at the pyloric aperture, forming a circular sphincter band, which contracts and keeps back the food in the stomach until gastric digestion is nearly completed.

The food, now called the *chyme*, passes into the small intestine, a tube some 20 feet long. This tube, besides the muscular and mucous coats, possesses in addition an external coat of loose fibrous tissue, covered by a single layer of flat epithelial cells. This coat is prolonged into, and helps to form the mesentery, a membrane connecting the intestine with the abdominal walls, which are lined with a similar fibro-epithelial coat. This membrane is called the peritoneum, and is sometimes inflamed (peritonitis) as a result of cold, injuries, &c. The small intestine is somewhat arbitrarily divided into three portions—the upper (duodenum), the middle (jejunum), and the lower (ileum). In all parts the muscular coat is similar to that of the rest of the digestive system. The mucous coat contains glands very like the pyloric glands of the stomach, called Lieberkuhn's follicles. These, however, rarely branch. They secrete the intestinal juice. In the duodenum, one finds in addition highly-branched glands called Brunner's. These extend right down into the submucous coat. Little is known concerning their function. In both the mucous and submucous coats, and generally involving both layers, are found masses of tissue—lymphoid—similar to that found in a lymphatic gland (fig. 6). These are termed solitary glands, but it must be understood that they do not secrete any juice concerned in digestion. Their function is probably connected with the blood and the blood-corpuscles. Collections of these solitary glands,

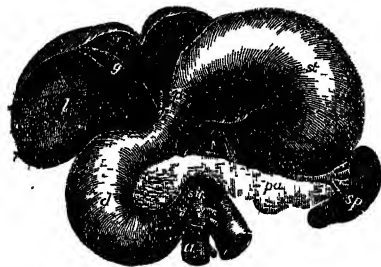

Fig. 5.—The under surface of the Stomach and Liver, which are raised to show the Duodenum and Pancreas: st, stomach; p, its pyloric end; l, liver; g, gall-bladder; d, duodenum, extending from the pyloric end of the stomach to the front, where the superior mesenteric artery, sm, crosses the intestines; pa, pancreas; sp, spleen; a, abdominal aorta.

forming oblong patches about two inches long, are called Peyer's patches. These are affected in typhoid fever. In addition to the follicles of

Lieberkuhn and the glands of Brunner, there are two very important glandular structures, the liver and the pancreas, which pour their digestive juices into the small intestine (fig. 5). The bile, which is the secretion of the liver, is formed continually by that organ, but the amount thus formed is greatly influenced by the kind and quantity of food taken. It passes out of the liver by the two hepatic ducts, and much of it passes by the cystic duct into the gall-bladder, where it is stored up.

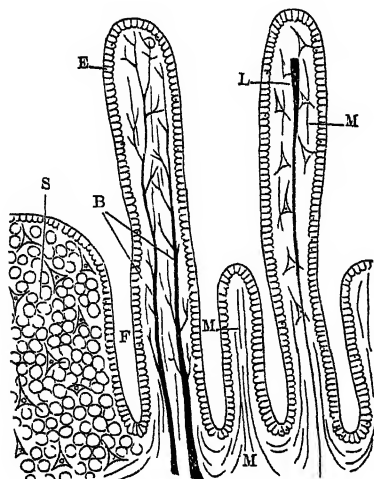

Fig. 6.—Section of Intestinal Mucous Membrane : L, lacteal in centre of villus; E, epithelium covering villus; B, blood vessels represented; F, follicle of Lieberkuhn; S, part of a solitary gland; M, muscular fibres.

From this the bile passes into the common bile duct, which joins the duct of the pancreas, and the two open into the duodenum by a common aperture. The bile is to be looked upon not only as a digestive juice, but as a drain or channel of excretion, whereby effete and useless matters are removed from the body. The flow of bile is easily restrained, as by inflammation of the duct, or the presence of a tumour pressing on the duct, or a gall-stone. In this case, the bile already formed is reabsorbed with the blood, through the lymphatics, and we have jaundice due to absorption of the colouring matter of the bile. The secretion of bile goes on before birth; the meconium of infants consisting chiefly of biliary matter. The pancreas is very similar in structure to a salivary gland. It secretes the pancreatic juice which pours with the bile into the digestive system. The mucous membrane of the small intestine contains, in addition to the structures already mentioned, little projections called villi (fig. 6). These are not, to any great extent at least, secretive, but they are important absorbents. This property they share with the whole of the digestive system, through any part of which, and especially through the walls of the stomach and small intestine, digested matter passes into the numerous blood-capillaries which form everywhere a dense network. The villi are peculiar, however, for each one contains, in addition to blood-vessels, a small lymph-vessel or lacteal. Nearly all the fat absorbed by the digestive system is taken up by the little cells of the villi, and passes on into the lacteals, and thence to the blood (fig. 7). If some osmic acid, which blackens fat, be poured into the intestine of a rabbit, killed during active digestion, and if the villi be examined with a microscope, they will be seen to have been blackened, especially at their

tips, while the rest of the intestine will have preserved its ordinary colour. On further examination it will be seen that the fat has been taken up in microscopic globules by the cells covering the villi, and that they are passing, in a way which is as yet not definitely settled, into the central lacteal.

The small intestine is a tube of great importance, and in order to increase its total area, the mucous membrane is elevated, in the upper part, into transverse folds (the valvulae conniventes, fig 8).

The unabsorbed food, mixed with the various secretions we have mentioned, now passes into the large intestine, when both digestion and absorption go on, although to a less extent. The large intestine is only 5 feet in length, but its girth is much greater than that of the small intestine. It commences with the caecum, a dilated part, into which passes a little blind canal (the vermiform appendix), a large and important structure in some animals. The food remnant (faecal matter) is prevented, under ordinary circumstances, from passing back into the small intestine, by a double fold of mucous membrane (the ilio-caecal valve, fig. 9). The large intestine ascends on the right side (ascending colon), crosses over to the left side (transverse colon), and descends again (descending colon), and makes a bend (sigmoid flexure), and finally terminates in a somewhat enlarged portion (rectum).

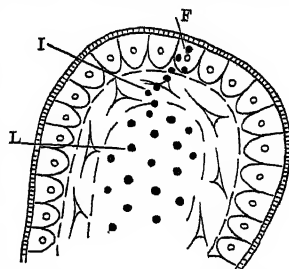

Fig. 7.—The Top of a Villus : Fat globules are represented as passing through one of the epithelial cells, F, on through the tissue of the villus, I, into the central lacteal, L.

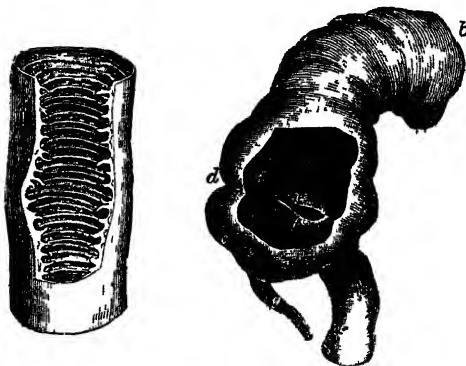

Fig 8—Small Intestine distended and hardened by alcohol, and laid open to show the valvulae conniventes.

Fig. 9.—Caecum inflated, dried, and opened to show the arrangement of the valve : a, termination of the ileum; b, ascending colon; c, caecum; d, a transverse constriction projecting into the caecum; e, f, lips of the valve separating the small from the large intestine; g, the vermiform appendix of the caecum

The anal aperture is closed by muscles, an internal sphincter of non-striped, and an external of striated fibre. The mucous membrane of the large intestine differs from that of the small intestine in containing no villi, or Brunner glands. Lieberkuhn's and solitary glands are present, but the aggregation of the latter into Peyer's patches is nowhere to be found.

*Movements of Food in the Alimentary Canal.*—When food is taken into the mouth it is at once swallowed, unless it is in the solid form. In this case it is chewed or masticated; the use of which is to divide the solid fragments taken into a convenient size for swallowing, for which purpose it, in addition, is mixed with the viscid saliva and juices of the mouth. The chewed food, moreover, is more easily digested, inasmuch as the gastric and other juices can act more readily upon finely divided than upon larger masses of food. Many animals can hardly be said to masticate; such are the carnivora (dog, cat, &c.), and they are not provided with grinding teeth. In most animals living on vegetable food, which frequently consists of hard grains, roots, and fibres, large flat grinding molars are found. In these animals, not only is the food finely divided in the mouth, but the food, largely consisting of starch, is partially digested by the saliva. In mastication, the head is firmly fixed by the powerful muscles of the neck, while the lower jaw is moved upon the upper. The lower jaw is approximated to the upper by powerful muscles (the temporal, masseter, and internal pterygoids), which pass upwards, and are attached to the side of the head and face. Their contraction may be felt by placing the hand in front of the ear and voluntarily contracting the jaws. The lower jaw is depressed by muscles which pass down the front of the neck. Most of these spring from the hyoid bone, which may be felt deep in the tissues of the neck above the 'Adam's apple.' Rotating movements and those of protrusion and retraction of the jaw are produced chiefly by the action of the pterygoid muscles. It is obvious that during mastication the food would naturally tend to escape from between the grinding surfaces of the teeth, and would collect within the mouth and outside the gums. This is prevented, however, by the muscles placed in the substance of the cheeks (buccinators) and lips (orbicularis oris). These keep the cheek and lip walls closely opposed to the outside of the teeth. On this account food will only escape from between the grinders into the interior of the mouth, from which it is collected and pushed back between the teeth by the muscular tongue.

The very complex muscular movements just described result from very perfectly co-ordinated nervous impulses, which pass from the brain to the muscles, and cause and regulate their contractions. One can masticate 'at will'—that is to say, one can consciously cause the muscles to contract. In order that the mastication may be effective, however, it is necessary not only to know the sizes, but also to be aware of the ever-changing positions of the particles of food. This is effected by sensory nerves, which pass to the brain from the mucous membrane of the mouth. Although mastication is frequently voluntary, yet, like most other voluntary actions frequently performed, it can be performed reflexly. In this case the sensory impulses pass from the mucous membrane to the brain, and initiate appropriate motor impulses which pass to the muscles, without exciting attention and special volition in their passage.

As a result of mastication, the food is gathered in the form of a round moist bolus on the upper surface of the tongue (see fig. 1). It is now ready to be swallowed. In the first place, it is pushed backwards by the tongue, and seized by muscles, many of which are attached to the hyoid bone, which can be felt to move during their contraction. According to the most recent investigation, the bolus is propelled with great rapidity through the pharynx and gullet into the stomach. If the finger be placed upon the hyoid bone, or Adam's apple, and the ear placed against the upper third of the back of a patient, the movement of the hyoid bone indicat-

ing the commencement of swallowing is almost coincident with the passage of food down the gullet, which produces a very audible sound. Following the propulsion of the food downwards, there is a wave of contraction, which, commencing in the pharynx, travels downwards through the gullet. This, however, is comparatively slow. It is seen then that swallowing is not due to the falling of liquids down the throat. A horse drinks 'up hill,' and the jugglers, or indeed any one, can drink or swallow with the head vertically downwards.

When the food has reached the back of the mouth, the rest of the act of swallowing occurs irrespective of the action of the will. The nerves, which commence in the mucous membrane of the pharynx and gullet (sensory branches of vagus), carry impressions to the brain, which disengage of themselves the appropriate muscular movements without necessarily involving either the will or consciousness. Thus, in alcoholic stupor, or fainting from drowning, in both of which conditions consciousness is suspended, food and liquid placed at the back of the mouth are at once swallowed.

There is a possibility that during swallowing the food may go the wrong way—i.e. it may pass into the larynx and windpipe. It will be seen from the diagram that the food in its passage to the gullet must actually pass over the aperture of the larynx. It is prevented from passing into it by the elevation of the larynx (this can be felt by the hand placed on the throat), which pushes its aperture against and under the back of the tongue, which at the same time is pushed backwards. In addition, there is a valve called the epiglottis, which is pushed down over the larynx by the movement just described, and by muscular fibres, which act upon it for that especial purpose. If the epiglottis be destroyed, as by ulceration, gun-shot wounds, &c., it is necessary for the patient to have the food he takes carried over the aperture of the larynx into the gullet by a feeding-tube. It is obvious that one cannot speak with the larynx shut, and with the larynx open we cannot safely swallow. Food is prevented from passing into the nose by the elevation of the soft palate which meets the constricting pharynx, and shuts off the cavity of the nose like a valve (fig. 1).

The walls of the stomach and intestine are, like the gullet, provided with muscular fibre. An external layer passes in the length of the gut, and within this is a circular layer. These muscles, unlike the muscles of the limbs, contract slowly on stimulation, and they are outside the domain of voluntary action. During digestion they contract peristaltically, urging the food towards the rectum. The peristaltic waves may begin in any part of the gut and pass slowly downwards, followed at varying intervals by other waves. It is probable that what is called antiperistaltic waves may occasionally occur, tending to bring the food back towards the mouth, for bilious matter is frequently vomited, the bile having in all probability passed upwards into the stomach by antiperistalsis from the duodenum.

Eruptions are frequently caused by antiperistalsis, and by a movement of this kind food is brought back into the mouth for further chewing in the ruminants (sheep, oxen, &c.). The peristalsis is particularly active during digestion, and is produced in great part by the food stimulating the mucous membrane. If a portion of the intestine or the stomach be removed from the body, peristalsis may continue or may be produced artificially, especially by irritating the mucous membrane. In the body the canal is under the influence of additional nerves (vagus), through which fibres the digestive processes are chiefly regulated among themselves.

The peristalsis in the stomach is combined with irregular churning movements.

The act of vomiting is a reflex nervous act. It can be excited by stimulating the branches of the vagus nerve, which are distributed to the stomach, as when indigestible and irritative food is taken; or emetics, such as mustard, hot water, or a hot saline solution, tartar emetic, ipecacuanha, sulphate of zinc, and alum are administered. By tickling the back of the throat with a feather, the glossopharyngeal nerve is stimulated, and vomiting may readily be produced. It is of frequent occurrence when painful irritation of the uterine nerves in pregnancy, of the nerves of the liver and kidneys during

the passage of a hepatic or renal stone, or indeed when irritation of any sensory nerves takes place. Nerve-impulses may pass to the brain through any one of these channels (fig. 10), or may be excited in the brain itself by the sight or smell or even the thought of anything disgusting, and they produce, if the person be conscious, a feeling of nausea. In any case there is a discharge of nerve-impulses, which, as a result of this stimulation, passes to the glands of the mouth through the chorda tympani nerve, and produces a rapid flow of saliva. In addition, motor nerves carry impulses to the muscular walls of the abdomen, and to the walls of the stomach itself. As a result of the muscular contraction which follows, the contents of the stomach are propelled upwards into the mouth. Just before vomiting an inspiration generally occurs, and the aperture of the larynx (glottis) is closed.

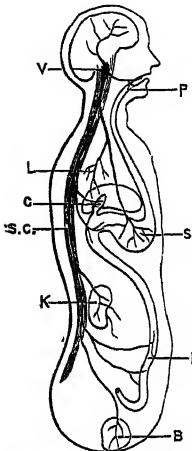

Fig. 10. — Sensory Nerves concerned in Vomiting:

Nerves come to vomiting centre V, through spinal cord SC, from pharynx P, lungs L, gall-bladder G, stomach S, kidney K, intestine I, and bladder B.

The diaphragm—the muscle which separates the thorax from the abdomen—then becomes pressed down upon the abdominal contents, and assists in the act of vomiting. Cases in which irritating or poisonous substances are swallowed are so frequent, that every one should be aware that a large quantity of hot liquid, especially if it contain much salt, or some mustard, forms a safe and speedy emetic. Ice is a valuable sedative, and often prevents vomiting. The undigested food when it reaches the lower part of the intestine (rectum), excites sensory nerves which carry impulses to the brain and spinal cord. A feeling of distension results, and voluntary contraction of the abdominal muscles and of the diaphragm—an inspiration usually taking place—expels the undigested matter. This voluntary effort is aided by the contraction of the bowel itself, and by the relaxation of the band of muscular fibres (sphincters) which, during the intervals between evacuations, remain contracted.

In many animals, such as the sheep, ox, and camel, the stomach consists of several cavities communicating with one another. In the ox and sheep both the cardiac and the pyloric portions are each subdivided into two compartments. The cardiac part consists of a very dilated cavity, the paunch (rumen), into which the food is passed as soon as swallowed. In addition there is a smaller part, the reticulum (honeycomb), so called from the folds of lining mucous membrane which intersect, forming a reticulum. The pyloric half is divided into two

parts. The psalterium (maniples), so called from the lamellated appearance of its mucous membrane, communicates with the last division, the rennet stomach (abomasum, fig. 11).

Fluid passes either into the first, second, or third parts of the stomach, and thence on into the fourth. Solid matter, such as grass, roots, &c., passes either into the paunch or reticulum. This is mixed with the saliva swallowed with it, and in addition it is mixed with juices formed by the mucous membrane of these cavities. When the animal has finished feeding, it lies down and rumination commences. Due in part to the contraction of the abdominal muscles and diaphragm, the food is propelled in the form of rounded pellets from the paunch and reticulum up into the mouth. The pellets are there thoroughly masticated, and are returned in a pulpy condition to the stomach. Now, however, the food passes into the psalterium, and finally into the rennet stomach. It will be seen, therefore, that the consistency of the food determines into which part of the stomach it passes. The walls of the stomach near the gullet are thrown into two folds

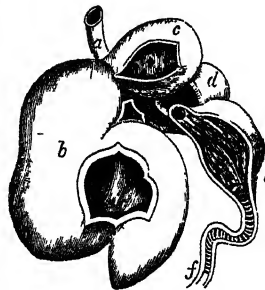

Fig 11.—Compound Stomach of Ox:

Fig. 12.—Alimentary Canal of Fowl:

a, cesophagus; b, crop; c, proventriculus, or secreting stomach; d, gizzard, or triturating stomach; e, intestinal canal; f, two long caecal tubes indicating the theoretical commencement of large intestine

or lips which, when in contact, form a tube leading from the gullet into the psalterium. Along this tube the masticated and fluid food can pass. The mouthfuls of grass which are first swallowed pass between their lips, and find their way at once into the paunch or reticulum.

In the bird some interesting modifications in the structure of the alimentary canal are seen (fig. 12). The gullet at about the middle of its course is provided with a pouch or crop. Into this the food passes, and is bathed by a secretion formed by its glands. It is then propelled onwards into a dilated cavity, the proventriculus, and is acted on by digestive juices. Thence it passes into the gizzard. This cavity is provided with muscular walls of enormous thickness in the case of birds that are vegetable-feeders. It is lined by thick and corneous epithelium, and in its interior are generally found pieces of stone, chalk, &c. The gizzard is a powerful mill, which grinds the food into a soft pulp, upon which the digestive juices can readily act (see BIRD).

*The Action of the Digestive Juices.*—By digestion is meant that process by which food is rendered capable of passing through the walls of the digestive system into the blood-vessels and lymphatics, in such a form that it may be of use to the economy. The most essential change which food undergoes is one of solution. Many proteins, starch, fat, and other food-stuffs are quite insoluble in the circulating fluids of the body, and were they injected into the blood they would simply block up the smaller blood-vessels. During digestion these pass either into nearly allied chemical substances which are readily dissolved in water, or in the case of fat partly into a soluble soap, and partly into a state of microscopically minute subdivision. It is not sufficient, however, merely to have a soluble food-stuff in order that it may be absorbed and used by the body. Cane (table) sugar is soluble in water, but it is of no use as cane-sugar to the body. If injected into the blood-vessels, it is at once secreted by the kidneys. During digestion it is converted into another sugar less soluble, but in a form which can be used by the economy.

It must clearly be understood that food introduced into the stomach is not received into the system. It is still 'outside the body.' It is only when it has become absorbed, and has passed in a suitable form, carried by the blood, to the tissues or the brain, muscles, &c., that it is made use of in so-called vital manifestations. The relief and stay that a meal gives is chiefly due to nervous action, the result of gastric distension. Clay and other non-nutritive matter may be swallowed, and will temporarily produce the same effect.

The digestion of food is brought about by the action of juices, the saliva, the gastric, pancreatic, intestinal, &c. These are mixed with the finely divided food by the movements of the alimentary canal. The digestive juices are in all cases secreted by the microscopic cells which line the various glands opening into the digestive system. The digestive juice, whatever be its source, contains either an acid substance or an alkaline one, and in addition a substance termed an unorganised ferment. These ferments differ in many particulars from the organised ferments (bacteria, micrococci), found in putrefaction, diseases such as anthrax, scarlet fever, cholera, &c. The latter are whole living cells, having definite parts or organs. They live and multiply, consume, and excrete in the fluid they inhabit. The digestive ferments are not whole cells, they are the *products of cells*. They are not the broken-down useless substances, such as carbonic acid, water, &c., which all cells give out, and which an animal, like man (an aggregation of cells), excretes. They consist of very complex active matter, of which we know almost nothing, and which we class with some other substances of which we know little more, under the head 'albuminoids.' These ferments in fact possess many of the qualities of cells themselves. They are killed by the temperature of boiling water, like all other living things. They have a certain range of temperature, within which alone they evince activity, and within the limits of that range they are more active the higher the temperature. Then again they require the presence of water, in which fluid they are soluble. In their action they seem to be hydrolytic, that is, they produce important changes in the substances they attach by, amongst other things, adding the elements of water. These digestive ferments, together with the other constituents of the digestive juices, are secreted by the cells of the digestive glands. If we study these glands and their cells with the microscope, they all present several points of similarity. Each gland has a duct, which, as in the case say of the salivary glands, divides into several branches. The duct,

or its branches in the latter case, terminate in the secreting tubules of the gland. These are little tubes, which are lined by the secreting cells, leaving only a small cavity in the centre of each tubule for the escape of the secretion into the duct. Outside the tubule there is a dense network of fine blood-capillaries, from which the liquor of the blood escapes, bathing the gland and the cells within it. These imbibe the liquor, and they have almost certainly the power of selecting such constituents of it as they require. The substances derived from the blood are used by the cells, which manufacture the juice which they excrete. The constituents of the excretion are not found, it will be observed, in the blood; they result from chemical processes which go on within the cells, which use blood as a raw material. The cells are very small, being about  $\frac{1}{1000}$ th to  $\frac{1}{100}$ th of an inch across. They have each a very thin envelope, within which the finely granular contents of the cell are seen. In the centre is a kernel or nucleus. During digestion the cell enlarges, and granules appear in it. These are the manufactured products: they are discharged into the duct of the gland.

We have now to consider how it is that the glands are regulated in their secreting powers, how it is that at certain times, and in sufficient quantity, the secreting juice is poured into the digestive system. This is brought about by the action of the nervous system. Although in some cases—e.g. the stomach, local nerve-cells placed in the walls of the digestive system itself, seem to regulate in part the secretion, yet in all cases nerve-cells placed in the brain are chiefly concerned. It was thought at one time that the brain acted by causing the blood-vessels of the gland to enlarge, and in consequence the food-supply and secretion of the gland to become greater. That this is not the whole truth, is shown by the administration of belladonna. If a rather large dose of this drug be taken, the mouth becomes very dry and unpleasant, and it is difficult to speak and to swallow. In other words, the cells of the salivary glands are paralysed, and the customary flow of saliva is for the time being at an end. It is found, however, that during this condition the blood-vessels are by no means contracted. This experiment, together with others, suggests that although during the secretion of a digestive juice the blood-vessels dilate, the activity of the secreting cells is not always associated with the condition of the blood-vessels. The latter are undoubtedly under the influence of nerves (vaso-motor) which regulate their condition, and it is probable that the secreting cells are themselves under the influence of other nerves, which are special secreting nerves. We have already seen that in the case of the movements of the digestive system, the motor-impulses which started from the central nervous system were called into action by sensory impulses starting from the mucous membrane of the digestive system. So in like manner the nervous impulses which pass to the blood-vessels and the glands are caused, in the first instance, by sensory impulses from the mucous membrane. If food be taken into the mouth, especially if it be 'tasty,' a secretion of saliva rapidly follows, and even the tickling of the mouth by a feather, or the stimulation of the mucous membrane with electricity, will produce the same result. In this case sensory impulses pass to the brain through such nerves as the lingual and glossopharyngeal, and reflexly excite the glands through the medium of the brain, the outgoing impulses passing through nerves such as the chorda tympani (fig. 13). See BRAIN. In the case of salivary secretion, the smell or sight of food may excite a secretion. In this case the sensory impulses pass from the nose or eye along the nerves of these organs to the brain. When the thought of food produces a flow,

this is due to the recalling of previous sight and smell impressions in the brain.

When food is passed into the stomach, secretion occurs. This too may result from mechanical irritation, as when through an opening (fistula) the mucous membrane is brushed with a feather. In all cases the stomach, pale before, becomes suffused with blood, and the gastric juice is poured out.

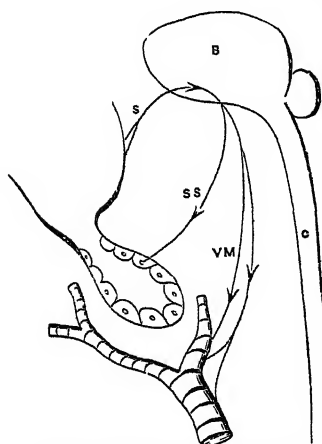

Fig. 13.—Nervous Mechanism of Secretion:

B, brain; C, spinal cord; S, nerve passing from mucous membrane of mouth to brain; SS, nerve passing to cell in salivary gland; VM, nerve passing to blood-vessels of gland.

various glands play in this important process. For our present purpose it is sufficient to speak of foods as belonging to four classes: (1) Proteins—albumens, globulins, &c.—e.g. the white of egg, the chief constituent of meat, the gluten of bread. (2) Carbohydrates—starches, sugars, gums—e.g. potato-starch, cane or grape sugar. (3) Fats and oils—e.g. suet, marrow, olive-oil. (4) Minerals—e.g. water, table-salt, iron, phosphates. See also DIET, FOOD, VITAMINS.

Some few substances are absorbed without being digested at all; they do not need to be. Such are water and the minerals, although even many of these undergo some change or other. Grape-sugar is absorbed, and probably proteins too are often absorbed to some extent at least. Fat is profoundly modified during digestion, although not necessarily as the result of any digesting ferment. It may be said, however, that the great mass of food-stuff which is classed under the heads of proteins and carbohydrates is all digested by the action of ferment-like bodies. The saliva, of which about 30 ounces are secreted during the 24 hours, contains a ferment termed *ptyalin*, which is capable of turning starch into a soluble sugar called *maltose*. This can easily be demonstrated in the following manner: Take a tiny pinch of ordinary starch powder, and shake it up with a tablespoonful of water. It will not dissolve. Then boil it, when the starch will swell up, forming a thin starch paste. Dilute a few drops of tincture of iodine with several volumes of water, and add a drop of this to a small quantity of the starch paste. It will become of a rich blue colour. This is the test for starch. Now add to some of the original starch paste about one-quarter of its volume of saliva from the mouth, and keep the mixture by the fire at a temperature pleasant to the hand. In a minute or so take out some of the starch in order to test it again. The iodine no longer gives a blue colour, but produces a beautiful mahogany brown.

This shows that the starch has disappeared, the brown colour being the reaction given by erythro-dextrine into which the starch has been converted. After a little time another portion tested in a similar way gives no reaction whatever, the erythro-dextrine having in its turn disappeared. The starch is now converted into sugar, mixed with a little unconverted dextrine. The *ptyalin* may be extracted from the saliva or from the salivary glands themselves. It does not appear to be much exhausted during its activity, and has the general characters already discussed of unorganised ferments. The saliva is alkaline, and the starchy food is no doubt partly converted into sugar during its sojourn in the mouth and gullet by its action. When the food has reached the stomach and the acid gastric juice has mixed with it, the saliva is unable to act, and is probably killed. This mixture does not take place until the gastric juice has been secreted, and until the churning movements of the stomach have commenced. As this does not take place for, say, a quarter of an hour after food has entered the stomach, the swallowed saliva has time to act, and to convert a large quantity of the starch into maltose. Any undigested starch is subsequently converted into sugar when the food reaches the small intestine by the pancreatic juice.

When the food reaches the stomach it causes a reflex secretion of gastric juice. This is but slowly produced when insipid heavy food, such as coagulated white of egg, boiled meat, sago, &c., is eaten, but flows readily when soups, broths, and fluids containing salts and extractions in abundance are taken. Thus we have a scientific reason for commencing a dinner with soup, preserving the *pièce de résistance* until the stomach has secreted gastric juice for its digestion. The gastric juice, several pounds of which are secreted daily, is acid in reaction containing free hydrochloric acid. In addition lactic and butyric acids are formed during the progress of digestion. The ferment peculiar to the stomach is termed *pepsine*, and it requires, unlike the *ptyalin* of the saliva, an acid medium for its action. Pepsine and hydrochloric acid convert proteins into substances termed *peptones*. The latter bodies are soluble in water, and are not coagulated by boiling like many of the proteins. In addition they pass readily through an animal membrane, and are therefore easily absorbed. The protein does not pass directly into the peptone, but like the starch is changed into at least one intermediate body. In the first case the protein becomes converted by the hydrochloric acid into what is called *syntonin*, or acid protein, and it is this *syntonin* which alone the pepsine has power to change into *peptone*. The *syntonin* becomes a *propeptone* which is intermediate in its properties between a protein and peptones itself. It is very probable that the whole change from protein to peptone consists in some simple change in the molecular character of the protein, together with the addition of water. A peptone may be termed therefore a hydrated protein, and the pepsine a hydrolytic ferment. Within the stomach, and capable of being readily extracted from the stomach of a calf, is a ferment called the milk-coagulating ferment (*rennet*). This causes milk to coagulate, and form a clot or curd. It subsequently contracts and squeezes out some fluid termed the whey. It is difficult to assign any use to this ferment, for the acid of the gastric juice would cause of itself the milk to curdle. Still more difficult is it to explain the existence of a similar ferment in the pancreatic juice, for we cannot suppose that any milk can even pass through the stomach to be subjected to its action. The milk indeed often forms dense clots which cannot afterwards be digested, and which cause

considerable gastric irritation. Milk when drunk is frequently found to disagree with some stomachs; but even in such cases it may often be 'sipped' with impunity. In this case the formation of large clots is prevented. Lime-water causes the milk to coagulate in small soft clots.

The products of digestion,  $\gamma$  ptone and sugar, together with water and many soluble salts, are absorbed into the blood-vessels which ramify in the gastric mucous membrane. When gastric digestion is over, the undigested food (chyme) passes through the relaxed pyloric sphincter into the small intestine. The chyme consists of some protein and starchy matter, together with fat and oil and indigestible substances, such as vegetable fibre, pure wax, cartilage, &c. mixed with gastric juice. Intestinal digestion is an alkaline one, and all the digestive juices of this part of the digestive system are alkaline in their reaction. They soon counteract the acidity of the chyme, which now becomes alkaline. The alkaline pancreatic juice, indeed, flows as soon as an acid is introduced into the duodenum, and the explanation of this flow is as follows: The secretion of the duodenum contains a substance called 'prosecretin.' This when acted upon by the acid gastric juice forms 'secretin,' which, when absorbed and carried by the blood to the pancreatic cells, causes them to secrete their juice. The proteins which remained undigested by the stomach are now acted upon by a ferment called trypsin found in the juice of the pancreas. This converts the proteins into peptones through an intermediate propeptone. The protein is said to be broken down by this trypsin into amino-acids, such as leucine and tyrosine, &c., in large amount. We must remember, however, that an experiment with a glass vessel—in which most of the experiments were made—is quite different from the digestion of an animal, where the products are being continually removed through the absorbing mucous membrane. It is, therefore, a question whether the peptone is absorbed at once, or whether it is further broken down in the intestine. We now come to a subject which has been elucidated during the last few years, chiefly through the labours of Pawlow and Starling. The fresh juice of the pancreas has a very slight action on proteins—so slight, indeed, that a careful experimenter like Claude Bernard overlooked its action. If fresh pancreatic juice and fresh intestinal be mixed together, the mixture has a most powerful action on proteins. The explanation of this is as follows: The intestinal juice contains a ferment which has been termed enterokinase, which is able to convert a precursor of trypsin, termed trypsinogen, into the active ferment trypsin. The trypsinogen has no action on proteins. The pancreatic juice contains other ferments which operate during digestion, notably a hydrolytic ferment, similar in its action to ptyalin, whereby the remaining starch is converted into sugar. The juice itself is thick and viscous. It is strongly alkaline and secreted in rather small quantity. It is said to possess a ferment capable of splitting oil and fat into glycerine and fatty acid, which it does by adding water to the fat, which is then decomposed. The fatty acid unites with the free alkali present, and a soap is formed which is subsequently absorbed. The alkaline contents of the alimentary canal also emulsify fat; i.e. they cause it to become very freely divided, forming a milky fluid. The minute microscopic globules which result pass readily through the walls of the alimentary canal into the lymphatics (lacteals). The emulsification of an oil can readily be shown by adding about half its volume of carbonate of soda (3 per cent.) solution to cod-liver oil.

The intestinal juice, the secretion of Lieberkuhn's follicles, is strongly alkaline. It assists in the digestion of starch and of protein matter. In addition an important ferment called 'invertin' is found. This has the power of changing cane into grape sugar and an allied substance, levulose. Both these bodies have the same formula, but differ from one another in their action on polarised light:

The importance of this ferment will be appreciated when we consider how large a quantity of food is taken in the form of cane-sugar, and that cane-sugar introduced into the blood is not of any use to the body, and is eliminated at once by the kidneys. The bile may be looked upon both as an excretion from the body and as a digestive juice. The colouring of the faeces and urine is due in part to a pigment hydrobilirubin (urobilin), which is an altered bile pigment. If bile is excreted rapidly, the faeces are dark in colour, and they may be white owing to deficient excretions. Many substances such as mucin, cholesterin, &c. found in the bile are excreted to form part of the faeces. On the other hand many bile constituents, such as the bile salts, are reabsorbed and used again in the economy. Bile has an important action in digestion, as may be shown by making biliary fistula in dogs, whereby the bile leaves the body at once through an aperture in the abdomen. In this case the animal loses flesh; the fat which it takes with its food passes unabsorbed through its digestive system, and its excretions are offensive. The bile seems then to assist in fat absorption, and to have some antiseptic action whereby putrefaction is prevented or lessened within the digestive system. Bile assists in the absorption of fat not only by assisting in its emulsification, but also by helping in some way or other the epithelial cells, covering the villi to take up the minute fatty particles. In addition it is supposed to stimulate minute muscular fibres within the villi, which by their contraction pump the absorbed fat on into the larger lymphatics.

Within the small intestine most of the food undigested by the stomach is rendered fit for absorption. This takes place through the tissue of the mucous membrane; much of the sugar and peptones find their way into capillary blood-vessels. Absorbed products, and notably fat globules, pass into the lacteals, and thence into the blood, circulating through the veins at the root of the neck. The contents of the lacteals during absorption are called *chyle*. The contents of the small intestine pass into the large intestine, where digestion occurs to a very slight extent. Absorption is, however, more rapid, and the contents become far more solid as they pass towards the rectum, due to the deprivation of water and soluble substances. The absorptive power of the large intestine is important to remember; for injections per rectum of liquid food, especially if it has already been artificially digested, may frequently sustain life for long periods.

*Artificial Digestion.*—The digestive juices are occasionally defective in amount or in quality, and in this case they may be supplied artificially. All the digestive ferments may be separated by very simple processes from the glands which secrete them, and many may readily be obtained in the market. Pepsine and hydrochloric acid, taken with or before a meal, are often of great service, the most reliable preparations of pepsine being the ordinary pepsina porci. Food may be digested *outside the body* before its administration. Beef-tea and milk-gruel may be prepared in the following

way: To bring the food to the proper temperature, boil half of it, mix it with the other half, and keep warm near the fire. To this add a preparation of the pancreatic ferments. The food should now be kept warm for an hour or so, and then boiled in order to prevent any further action of the ferment. It may be taken by the mouth or administered as an enema. Preparations of the pancreas are alone to be used in peptonising food outside the body, as pepsine preparations produce a bitter and unpleasant taste. Pancreatic preparations, on the other hand, are useless when taken with the food, as they are destroyed within the stomach.

See BLOOD, CHYLE, LYMPH, BILE, SALIVA, PEPSIN, ABDOMEN, GLANDS, DIET, FOOD, COOKERY, ALCOHOL, INDIGESTION, VITAMINS, &c.

**Digitalis**, a genus of Scrophulariaceæ, natives chiefly of the south of Europe and temperate parts of Asia. One only, the Common Foxglove (q.v.), (*D. purpurea*), is a native of Britain. Other species have been introduced, notably *D. lutea* and *D. grandiflora*, with yellow flowers.

The leaves of the *Digitalis purpurea*, collected before the expansion of the flowers and dried, are largely used in medicine, either in the form of powder, or as tincture or infusion. Digitalin granules, containing minute quantities of a mixture of the active principles, are also employed. The leaves owe their activity to the presence of certain bodies, which have been named digitalin, digitalein, digitoxin, &c. The leaves and their preparations have a bitter taste. When given in large doses by the mouth, they produce violent vomiting and purging; this may prevent their absorption into the blood, but if absorbed, they may cause death by paralysing the heart's action. When the leaves are administered in medicinal doses, a peculiar action is exerted on certain of the nerves, and on the muscular substance of the heart and blood-vessels, causing the heart to beat more slowly, regularly, and powerfully, and the smaller arteries to contract. By this combined action the blood-pressure is raised, and if dropsy be present, a diuretic action is exerted. Digitalis is used in many organic forms of heart-disease, in nervous and functional irregularity of the heart's action, in cardiac weakness from long-continued disease, in oedema of the lungs, internal hemorrhages, and other conditions. When taken for a long time it may cause nausea and other digestive disturbances, and in a very few cases sudden and serious symptoms of poisoning come on. This constitutes the so-called *cumulative* action of digitalis. In therapeutic doses digitalis should slow the pulse; if too large doses be given, the pulse becomes rapid and irregular.

**Digitaria**. See MILLET.

**Digitigrada**. See CARNIVORA.

**Digne**, a cathedral city in the French department of Basses-Alpes, on the Bléonne, 70 miles NE. of Marseilles; pop. 6300.

**Dihong**. See BRAHMAPUTRA.

**Dijon**, chief town in the French department of Côte-d'Or, formerly capital of the old duchy of Burgundy, lies, spread out on a fertile plain at the foot of Mont Afrique (1916 feet), at the junction of the Ouche and Suzon, and on the Canal de Bourgogne, 190 miles SE. of Paris. Its importance as a railway centre has rendered it of consequence in the inner line of French defences towards the east, and strong forts now crown the neighbouring hills. The environs are exceedingly beautiful, and the town is well and regularly built; the streets are broad, the open squares numerous, and the old walls have been turned into tasteful boulevards. Of the mediæval defences, the Gothic castle built

by Louis XI. still remains; formerly it was a state-prison, in which, among others, Mirabeau, Tousseint L'Ouverture, and General Mack were confined. Among the public buildings, which are numerous and imposing, the chief are the cathedral, a massive Gothic structure, dating from the 13th century, with a wooden spire (1742), 301 feet high; the churches of Notre Dame (1252-1334), St Michel (1529), and others; a handsome theatre; the palais de justice; and the former palace of the Dukes of Burgundy, which, commenced in 1366, is now used as the town-hall, and contains a rich museum and a library. Dijon is also the seat of a university with three faculties—law, science, and letters—and possesses in addition a theological seminary, a botanic garden, and an academy of art. The manufactures include liqueurs, brandy, machinery, and mustard, and there is a noteworthy trade in wool, flowers, and agricultural produce; but Dijon's chief commercial importance is as the centre of the Upper Burgundy wine trade. Pop. (1872) 40,116; (1921) 78,578. The *Dibia* of the Romans, Dijon in the 5th century passed from the Burgundians to the Franks, in the 9th was ruled by counts of its own, under the suzerainty of the bishops of Langres, but in 1007 was united to the duchy of Burgundy, of which it became the capital. On the death of Charles the Bold it came with Burgundy into the possession of France in 1477. In October 1870, after a sharp engagement before the city, Dijon capitulated to a German force. There was again severe fighting here in January 1871. Charles the Bold, Crébillon, Bossuet, and Rameau were natives, and close by is the birth-place of St Bernard, of whom there is a statue by Jouffroy (1847).

**Dike**. See DYKE.

**Dilapidation**, in English law, is where an incumbent suffers his parsonage-house or outhouses to fall down, or be in decay, for want of necessary reparation; or pulls down or destroys any of the outhouses or buildings belonging to his living; or destroys woods, trees, &c.; for it is said to extend to committing or suffering any wilful waste on the inheritance of the church. Dilapidation is a species of the legal injury known as Waste (q.v.). A rector or vicar is bound to keep his residence and the chancel of the church in repair, but not to supply or maintain anything in the way of ornament, as painting, white-washing, or papering. An ecclesiastical person suffering the church-property to get out of repair is subject to an action for dilapidation at the instance of his successor; and the money so recovered must be applied to the repairs. The incumbent is not liable for dilapidation occurring during long leases. A surveyor of dilapidations is appointed in each diocese, who, when so ordered by the bishop, may inspect and report on the buildings of a benefice which is not vacant. But the bishop can issue such orders only on receipt of a complaint from the archdeacon, the rural dean, or the patron of the benefice that the buildings of the benefice are dilapidated, and must give a month's previous notice to the incumbent, who is entitled to state written objections to the report within a month, whereupon the bishop may either call in another surveyor to report on the issues of fact, or take counsel's opinion on the issues of law, the incumbent paying the cost of such proceedings, and being obliged to comply with the bishop's final decision. The incumbent must execute the works specified in the report, as settled by the bishop, in the manner and within the time therein prescribed, or such longer time as the bishop may appoint in writing. Or he may, with consent of the bishop and the patron, and the surveyor's approval, substitute other works for them. In cases of dilapi-

dations in vacant benefices, the sum for repairs named in the bishop's order is a debt due from the late incumbent, his executors and administrators, to the new incumbent, and is recoverable at law or in equity. For the corresponding Scottish law, see HERITOR, MANSE.

### Dilatory Pleas. See PLEA.

**Dilemma.** A true dilemma is defined by Whately as 'a conditional syllogism with two or more antecedents in the major, and a disjunctive minor.' The following dilemma, of the kind called destructive, will perhaps convey a clearer notion than any definition. 'If this man were wise, he would not speak irreverently of Scripture in jest; and if he were good, he would not do so in earnest; but he does it, either in jest or earnest; therefore, he is either not wise, or not good.' There being two conclusions, one or other of which your opponent must admit, he is in a manner caught between them; hence we speak of the *horns* of a dilemma.

**Dilettanté** (pl. *dilettanti*, Ital.), in its original sense, is synonymous with an *amateur*, or lover of the fine arts. It is often used as a term of reproach, to signify an amateur whose taste lies in the direction of what is trivial and vulgar, or of a critic or connoisseur whose knowledge is mere affectation and pretence. It is sometimes assumed, in a spirit of self-depreciation, by those who are unwilling that their critical acquirements, or artistic productions, should be judged by the rules which would be applied to those of persons who had made a professional study of art. It was in this sense that it was assumed by the Dilettanti Society, a body of noblemen and gentlemen by whose exertions the study of antique art in England has been largely promoted. The society was founded in 1734, and thirty years later it sent out an expedition to make drawings of the most remarkable artistic monuments of antiquity, under Chandler, the editor of the *Marmora Oxoniensia*; Revett, joint-author with Stuart of a great work, *Athenian Antiquities*; and Pars, as artist. They returned in 1766; and four splendid folios on the *Antiquities of Ionia* appeared in 1769, 1797, 1840, 1881. Other publications were *Specimens of Ancient Sculpture* (1809-35), *Bronzes of Siris* (1836), and *Athenian Architecture* (1851; new ed. 1889). See Lionel Cust's *History of the Society* (1898).

**Diligence**, in the Law of Scotland, is a term used in various significations. (1) It means the care incumbent on the parties to a contract with regard to the preservation of the subject matter. In this sense the term is also used in English law, which recognises three degrees of diligence—(a) common, such as men in general exert in managing their own affairs; (b) high, such as great prudence demands; and (c) low, such as persons of less than common prudence take in connection with their own affairs. (2) The warrants issued by courts for enforcing the attendance of witnesses and the production of writings. (3) The process of law by which person, lands, or effects are attached either on Execution (q.v.) or in security for debt. In the second of these senses, it corresponds to the English *subpoena*; and in the third, generally to execution.

**Dilke, CHARLES WENTWORTH**, an English critic and journalist, was born December 8, 1789, graduated at Cambridge, and served for twenty years in the navy pay-office. In 1830 he became proprietor of the *Athenæum*, and from that year until 1846 he filled also its editor's chair. He took over the *Daily News* in 1846, and managed it for three years. He died at Alice Holt, Hants, August 10, 1864. A collection of his articles contributed to the *Athenæum* and *Notes and Queries*

between 1848 and 1863 appeared in 1875 as *The Papers of a Critic: with biographical sketch by his grandson, Sir Charles Wentworth Dilke, Bart., M.P.* (2 vols.); the first volume treating Pope, Lady Mary Wortley Montagu, and Swift; the second, Junius, Wilkes, the Grenville Papers, and Burke. He is known also by his *Old English Plays* (6 vols. 1814).—SIR CHARLES WENTWORTH DILKE, only son of the preceding, was born in London, February 18, 1810, and educated at Westminster School, and Trinity Hall, Cambridge. He graduated as LL.B. in 1834, but did not practise. One of the most active originators, as well as member of the executive committee, of the Great Exhibition of 1851, he was sent as a commissioner to the New York Industrial Exhibition in 1853, and in 1862 he was one of the five royal commissioners for the second exhibition, and accepted a baronetcy. In 1865 he was returned to parliament for Wallingford, and in 1869 he was sent to Russia as the representative of England, to the horticultural exhibition held at St Petersburg. Here he died suddenly, 10th May of the same year.—SIR CHARLES WENTWORTH DILKE, son of the preceding, was born at Chelsea, September 4, 1843. He studied at Trinity Hall, Cambridge, where he graduated in 1866, being soon after called to the bar. His travels in Canada and the United States, Australia and New Zealand, he described in his *Greater Britain: a Record of Travel in English-speaking Countries during 1866-67* (2 vols. 1868). He was returned to parliament for Chelsea in 1868. He was a doctrinaire Radical in politics, and was once at least an avowed Republican, yet he held office as Under-secretary for Foreign Affairs, and afterwards President of the Local Government Board under Mr Gladstone. His connection with a divorce case led to his temporary retirement from public life. In 1885 he married the widow of Mark Pattison, herself the author of *Claude Lorrain, sa Vie et ses Œuvres* (Paris, 1884), and *The Shrine of Death* (1886). She died 24th October 1904. Author of *European Politics* (1887), and *Problems of Greater Britain* (1890), Sir Charles Dilke organised the Labour members into an influential party, and was an authority on national defence and foreign relations. Returned to parliament in 1892 for the Forest of Dean, he sat till his death, 26th January 1911. He was a contributor to *Chambers's Encyclopedia*. See Life by Gwynne and Tuckwell (1917).

**Dill** (*Anethum*), a genus of Umbelliferae, by some included in Peucedanum. The Common Dill (*A.*, or *P.*, *graveolens*) is an annual or biennial plant, which grows wild in the countries round the Mediterranean, but has from a very early period been in general cultivation as an aromatic, stimulant, and carminative, being used in cookery like anise, and in medicine as dill water, &c. *A. Sowa* is similarly cultivated, and used in Bengal, &c.

**Dilleniaceæ**, a tropical and subtropical order of archichlamydeous dicotyledons, resembling Magnoliaceæ in habit as well as structure, and often of no less beautiful foliage and flowers. There are about two hundred species, generally astringent, and hence frequently useful in medicine and tanning; many yield excellent timber, and some also fruit, that of *Dillenia speciosa* being especially eaten in India.

**Dillingen**, a town of Bavaria, on the Danube, 51 miles WSW. of Ingolstadt by rail, with two monasteries, a high school, a seminary, and a girls' deaf-and-dumb institution. In the old castle the bishops of Augsburg formerly resided, and here they founded a university (1554-1804), which from 1564 was an active Jesuit centre. Pop. 6000.

**Dillmann**, CHRISTIAN FRIEDRICH AUGUST, a great Orientalist, born 25th April 1823, at Illingen, in Württemberg. Already as a student at Tübingen his studies under Ewald's influence had been turned to orientalia, and in 1846-48 he visited the libraries at Paris, London, and Oxford, cataloguing the Ethiopic MSS. at the last two, and returning to Tübingen to join its teaching staff. In 1854 he accepted a call to Kiel, where he became professor of Oriental Languages in 1860, but was transferred in 1864 to the chair of Old Testament Exegesis at Giessen, which in 1869 he resigned to become Hengstenberg's successor at Berlin. Dillmann was beyond question the first authority in Europe on the Ethiopic languages. The best books for the student in this obscure department of learning are his *Grammatik der äthiopischen Sprache* (1857), *Lexicon Linguae Aethiopicae* (1865), and his *Chrestomathia Aethiopica* (1866). Other works are his German translations of the Book of Enoch (1853), of the Book of Jubilees or the 'Little Genesis' (1849-51), and the Book of Adam (1853) in Ewald's *Jahrbücher*, as well as editions in the original of the first two; and an edition of the ancient Ethiopic translation of the Old Testament, *Biblia Veteris Testamenti Aethiopica* (2 vols. 1853-72). His contributions to pure theology are *Ueber den Ursprung der alt-testamentlichen Religion* (1865), *Ueber die Propheten des alten Bundes* (1868), and fresh editions for the 'Kurzgefasstes exegetisches Handbuch' of Hirzel's commentary on Job (1869), as well as of Knobel's commentaries on Exodus and Leviticus (1880), and on Genesis (1882). Dillmann became in 1877 a member of the Berlin Royal Academy of Sciences, and contributed many papers to its issues. He was president of the fifth International Congress of Orientalists, and edited its *Abhandlungen* (3 vols. 1881-82). Other works (1879-84) deal with the history of the Ethiopic kingdom of Axum (q.v.). He died 4th July 1894.

**Dillon**, JOHN, the son of John Blake Dillon (1816-66), who was a prominent member of the Young Ireland party, and member for County Tipperary in 1865-66. Born in New York in 1851, he was educated at the Catholic University of Dublin, after which he became a doctor. He early identified himself with the Parnellite movement, and in 1880 was returned for County Tipperary. In the House of Commons Dillon soon became prominent for the violence of his language, while speeches delivered by him in Ireland led to his imprisonment in 1881, 1881-82, and 1888. From 1883 to 1885 he was absent from political life on account of ill-health; but in 1885 he was elected for East Mayo, and was repeatedly re-elected till 1918. 'Honest John Dillon' was one of the chief promoters of the 'Plan of Campaign.' In 1896-99 he was chairman of the main section of the Nationalists, and in 1918 of the remnant.

**Dilman**, a town of northern Persia, in the province of Azerbaijan, 75 miles W. of Tabriz; pop. 6000.

**Diluents**, medicines for diluting the blood and increasing the excretions, especially the urine. The simplest and best of diluents is water; but all watery fluids, such as lemonade, soda-water, beer, infusions, tea, milk, &c., are diluents. See DEMULGENTS.

**Diluvium**, a term formerly given by geologists to those strata which they believed to have been formed by the Deluge, and more particularly to the boulder clay. The altered opinions as to the origin of these beds have caused the word to fall into disuse in Britain. It is still used on the Continent, however, not in its original sense, but simply as a general term for the glacial and fluvio-glacial accumulations of the Pleistocene system. When

the adjective—diluvial—is employed by modern writers, it is to characterise those accumulations of gravel or angular stones which have been produced by sudden or extraordinary currents of water.

**Dime**, a silver coin, the tenth part of a United States dollar (see DOLLAR), and equal to about fivepence English.

**Dimension**. In Geometry, a point, since it has merely position, is said to have no, or to be of zero, dimensions; a line, straight or curved, is of one dimension—viz. length; a plane surface has two—length and breadth; while a solid is said to be of three dimensions—length, breadth, and thickness. Thus it will be seen that by the term dimension is meant a direction in which extension may be reckoned or measured. The three last-named dimensions are found sufficient to determine all known forms of extension. Hence space is tridimensional. The possibility of space of higher dimensions existing has been much discussed. Since points, lines, and surfaces in general generate by their motion lines, surfaces, and solids respectively, so it is held that some analogous generation of a fourth dimensional figure by one of three dimensions is conceivable. The subject, although interesting, is wholly speculative.—In Algebra, the term dimension is employed in much the same sense as *degree*, to express the sum of the indices of those letters with reference to which the term containing them is considered—e.g.  $xy$ ,  $x^2$ , are both of two dimensions, or of second degree;  $x^2y$ ,  $x^3$ , are of three dimensions, or third degree, &c.

**Dimidiation**, in Heraldry, a mode of marshalling arms, adopted chiefly before quartering and impaling according to the modern practice came into use, and subsequently retained to some extent in continental though not in English heraldry. It consists in cutting two coats of arms in half by a vertical line, and uniting the dexter half of the one to the sinister half of the other. Coats of husband and wife were often so marshalled in England in the 13th and 14th centuries.

**Dimity**, a stout, figured cotton-fabric, used chiefly for bed-hangings and window-curtains. The figure or stripe is distinctly raised. Originally dimity was commonly white or of a single colour; but variegated dimities are now largely made; one band or stripe of the cloth having a woven pattern in white alternating with a plain band—i.e. the fabric is all white as it comes from the loom. A pattern is afterwards printed in colours on the plain band.

**Dimorphism** (Gr. *dis*, 'twice'; *morphē*, 'shape or form'), a technical term applied in Biology to cases where an organism appears in two different forms. Thus in a colony of hydroids there may be 'dimorphic persons'—respectively nutritive and reproductive, and yet fundamentally the same in structure and origin. So too when the two sexes are markedly different, the term sexual dimorphism may be used. Or the organisms may be different at certain seasons and in certain conditions, as in summer and winter Butterflies (q.v.), or in the two kinds of common Primrose (q.v.) and cowslip. Sometimes three different forms of butterfly are known in the same species, and to such cases the term *trimorphism* is conveniently applied. The same is true of the common flower *Lythrum salicaria*. In hydroid and medusoid colonies (e.g. *Hydractinia* and *Siphonophora*) the development of multiple forms resulting from 'Division of Labour' (q.v.) is described as *polymorphism*. The same term is obviously applicable to the different forms exhibited by some social Ants (q.v.). The same set of terms may also be employed in reference to different forms of the same mineral, &c. See also FLOWERS, FERTILISATION.

An inorganic substance is in a somewhat analogous manner said to be dimorphous when it is capable of crystallising in two different forms or systems (see CRYSTALLOGRAPHY). A large number of substances have this property, of which sulphur, carbon, carbonate of lime, and iodide of mercury are the best examples. Thus carbon, as the diamond, crystallises, in the regular system, as octahedra, while as graphite, or Black Lead (q.v.), it forms hexagonal crystals belonging to the rhombohedral system. In some cases there is a great tendency for the one form of crystal to change spontaneously into the other form. The red iodide of mercury is a striking example of this. When heated, this substance is volatilised, and may be condensed on a glass plate as a yellow crystalline crust, consisting of rhombic plates. When this is rubbed, or even scratched, an immediate change takes place, the rhombic plates becoming broken up into octahedra, while the colour at the same time alters from yellow to a brilliant scarlet. So also when sulphur is crystallised from its solution in bisulphide of carbon, it yields transparent amber-coloured octahedra; but when melted sulphur is cooled, prismatic crystals are the result. In the course of a few days the prisms become opaque, owing to their being broken up into small octahedra, while conversely the octahedra, when heated to 230° (110° C.), are changed into smaller prismatic crystals. Those substances, such as sulphate and selenate of nickel, which crystallise in three systems, are said to be *trimorphous*.

**Dimsdale**, THOMAS (1712-1800), an English physician who wrote several works on inoculation, was famous as an inoculator (making journeys in 1768 and 1784 to Russia to inoculate the Empress (Catherine and other magnates), and sat for Hertford in two parliaments.

**Dinājpur**, capital of a district in the Rajshahi division of Bengal, stands 221 miles N. of Calcutta, on the Punabhaba River, which, through the Mahananda, enters the Lower Ganges; pop. 16,000.—The district has an area of 4000 sq. m., and a pop. of 1,700,000, almost entirely rural, and mainly of aboriginal descent. Two-thirds are Hindus.

**Dinan**, a very old town in the French department of Côtes-du-Nord, on the Rance, 30 miles NW. of Rennes, and 14 S. of St. Malo. The situation of Dinan, on the summit of a steep hill of granite, and with the Rance flowing through a valley 250 feet below, is romantic in a high degree. The valley is crossed by a fine granite bridge of ten arches. The town is still partly surrounded by its old ivy-covered walls. The old castle of the Dukes of Brittany is now in part used as a prison. In the older district the streets are crooked, narrow, and steep; in some parts, the overhanging houses, and arcades resting on carved granite pillars, present many picturesque architectural features. The church of St. Sauveur, a fine Romanesque church, contains the heart of the famous French warrior Bertrand du Guesclin, who here had a famous encounter with an English knight. The terraces around the town afford very charming views. Many English reside here. Pop. 10,000. Four miles off lies the village of Corseult, on an old Roman site, where many antiquities have been found.

**Dinant**, a town of Belgium, occupying a narrow site between the Meuse and a limestone hill, 17 miles S. of Namur by rail, and consisting mainly of one narrow street. On the cliff above stands the citadel (1530), and the Gothic church dates from the 13th century. There are manufactures of cotton, paper, leather, iron, &c., with black marble quarries; and the gingerbread of Dinant, com-

posed of rye-flour and honey, has an extensive sale. The place was formerly noted for its copper wares, familiarly known as *Dinanderie*, and still sold. Pop. 5000. Dinant, which dates from the 6th century, has suffered greatly from frequent sieges, and other war-like operations, as in 1914.

**Dinapore** (*Danāpur*), military headquarters of the district of Patna in Bihar and Orissa, on the Ganges, 12 miles W. of Patna city by a road lined with houses throughout. It is divided into two parts, the Cantonments and the Nizamut, or city proper. Pop. 40,000, of whom over 30,000 reside within the Nizamut. In the mutiny of 1857 the three sepoy regiments stationed here rose in July, and escaped into Shahabad district, where they attacked Arrah (q.v.).

**Dinaric Alps**, the name applied to the mountains connecting the Julian Alps with the Balkan system. The main range stretches from north-west to south-east, separating Dalmatia from Bosnia and Herzegovina, as far as the mouth of the Narenta; and a minor chain extends through the Dalmatian coast country. The mountains are principally calcareous; the highest summits are Orjen (6225) and Dinara (5940), and the mean height is 2300 feet.

**Dindigul**, a town in the presidency of Madras, 40 miles NNW. of Madura by rail, with an old fort, still in good preservation, commanding the approaches to Coimbatore from the south. It has a trade in hides, tobacco and cigars, coffee, and cardamoms. Pop. 25,000, three-fourths Hindus.

**Dindorf**, WILHELM, a famous Hellenist, born 2d January 1802 at Leipzig, where his father Gottlieb Immanuel Dindorf (died 1812) was professor of Oriental Languages. In 1817 he began his studies in philology at Leipzig, under Gottfr. Hermann and Chr. Daniel Beck, declined a call to Berlin in 1827, and next year accepted an extraordinary professorship at Leipzig, which he resigned in 1833 to devote himself entirely to his literary activity. Here he died, 1st August 1883. Dindorf's long life gave many contributions of the first value to Greek scholarship, especially in the region of dramatic poetry. Among his works were the preparation of vols. 7-13 of the great Invernizzi-Beck edition of Aristophanes (1820-34), editions of Aristophanes, with notes and scholia (1835-39), of Æschylus (1841-51), Euripides (1834-63), Sophocles, with notes (1832-36), and a second vol. of the series of scholia to Sophocles, edited by Elmsley (1852), also an edition with annotations and scholia of Demosthenes (1846-51), all printed at Oxford. Other works are those on the metres of Æschylus, Sophocles, Euripides, and Aristophanes (1842); the lexicons to Sophocles (1871) and Æschylus (1873-76); his edition of the text of Homer (1855-56), and of the scholia to the *Odyssey* (1855) and the *Iliad* (1875-77). With Hase and his brother Ludwig (1805-71) he edited the *Thesaurus Græcæ Linguae* of Stephanus (1832-65).

**Dingelstedt**, FRANZ VON, German poet, born near Marburg in 1814, was royal librarian at Würtemberg in 1843-50, intendant of the court theatres at Munich, Weimar, and Vienna in 1850-71, and afterwards director of the Hofburgtheater in Vienna. He was ennobled by the Austrian emperor, and died 15th May 1881. Besides several volumes of poems, displaying great versatility and considerable power, he published a series of novels, one fine tragedy (*Das Haus der Barneveldts*), essays, and translations and studies of Shakespeare. His collected works fill 12 vols. (1877).

**Dinghy**. See BOAT.

**Dingle**, a seaport on the north side of Dingle Bay, in County Kerry, Ireland, 27 miles SW. of

Tralee railway station, and 30 WNW. of Killarney. The chief exports are coin and butter. The harbour is landlocked. Pop. 1800.

**Dingo** (*Canis dingo*), a variety of Dog (q.v.) found in Australia, both in a wild and in a half-tamed state. It is probable that this dog, which is found in a semi-fossil state in some of the caves, was introduced by or with the earliest human

Dingo, or Australian Dog (*Canis dingo*).

inhabitants. The dingo has an elongated flat head, which is carried high; the ears are short and erect, and are kept in that position when the animal runs; the fur is soft and predominantly tawny; the tail is bushy and kept low down. It is a very muscular, fierce animal, tamable if taken young. In the wild state it seldom barks. The wild forms, joined doubtless by recent runaways from domestication, used to work very great havoc among the sheep, but vigorous endeavours have vastly reduced their numbers and lessened their ravages.

**Dingwall** (Scand., 'court hill'); the county town of Ross-shire, near the head of the Cromarty Firth, and at the entrance to the valley of Strathpeffer, 13½ miles NW. of Inverness (by rail 18½). It has a town hall, county buildings (1845), a monument to Sir Hector Macdonald (1906), and an obelisk, 57 feet high, which marks the grave of Sir George Mackenzie, first Earl of Cromarty. This obelisk, twisted by an earthquake, is to fall on a white-haired boy. A royal burgh since 1226, Dingwall united till 1918 with Wick and four other towns to return one member to parliament. Pop. (1861) 2099; (1881) 1921; (1921) 2323.

**Dinkelsbühl**, an ancient walled town of Bavaria, on the Wornitz, 19 miles NNW. of Nordlingen by rail, with manufactures of cordage, hosiery, straw-hats, pencils, brushes, &c. It was formerly a free city of the empire, and suffered much during the Thirty Years' War. Pop. 5000.

**Dinocera** (Gr. *deimos*, 'terrible,' and *keras*, 'horn'), an extinct order of mammals, approaching the elephant in size and movements, remains of which have been found extensively in the Eocene lacustrine sediments of southern Wyoming. The dinocera include three genera—*Uintatherium* (most primitive type), *Dinoceras* (intermediate form), and *Tinoceras* (youngest and most specialised). About thirty more or less distinct forms have been recognised. The feet were plantigrade, the fore-foot being larger than the hind-foot, and having five digits; the limbs were massive and heavy, but shorter than in the elephant; the skull was long and narrow, supporting on top three separate transverse pairs of high osseous protuberances or horn-cores, while the canine teeth were enormously developed in the male, and formed short, trenchant, decurved tusks; the nasal bones were elongated so as to form nearly half the length of the skull, though, as the neck was long enough

to allow the head to reach the ground, there was probably no proboscis; finally, the brain was proportionately smaller than in any other known mammal, and even less than in some reptiles. See Professor O. C. Marsh's admirable monograph, published by the United States Geological Survey (1884).

**Dinornis**. See MOA.

**Dinosauria** (Gr., 'terrible lizards'), an important group of Mesozoic reptiles, known partly by their skeletons, partly by their footprints. They were gigantic forms, some of them at least 80 feet in length, and many of their characters lead on to birds. Thus in the hip-girdle the pubic bones were in many cases turned, not forwards as in other reptiles, but backwards as in birds; the legs were also in part bird-like; the fore-limbs were less developed than the legs; some of the bones apparently contained air-cavities, &c. *Atlantosaurus* (q.v.), *Stegosaurus*, *Iguanodon* (q.v.), and *Megalosaurus* (q.v.) are important types. They begin in Triassic strata, become very prominent in the Jurassic fauna, continue well represented in the Chalk, and then terminate. A large number have been found in America, and our knowledge of them is mainly due to Cope and Marsh. They were terrestrial animals, though some, such as *Iguanodon*, frequented marshy ground. Some seem to have been carnivorous, others vegetarian. According to Seeley and Von Huene, Dinosaurs do not form a natural order, but include two distinct orders—*Saurischia* and *Ornithischia*. The latter point the way to birds. See REPTILES.

**Dinotherium** (Gr., 'terrible beast'), a remarkable extinct animal, the cranial bones of which are found in the Miocene and Pliocene of Germany, France, &c. The animal was provided, like the elephant and the walrus, with a pair of long tusks; but these projected from the end of the lower jaw, which is deflected downwards at a right angle to the body of the jaw. Both jaws possessed a series of præ-molars and molars, the crowns of which were traversed by strong transverse ridges. The nasal cavity was large, apparently supplying attachment for a trunk, as in the elephant. Very little is known

Dinotherium, as restored by Kaup.

of the skeleton except the skull (one example of which is 3½ feet long); and hence the true position of the dinotherium has not been satisfactorily determined. Cuvier and Kaup have referred it to the neighbourhood of the tapir, supposing it to have been an inhabitant of large lakes.

**Dinwiddie**, ROBERT, colonial governor of Virginia, was born in Scotland about 1690, and was governor of Virginia from 1752 to 1758, when he was recalled, after precipitating the French and Indian war, and by his ill-temper, avarice, and incompetence, rendering himself generally unbearable to the Americans. He died in 1770.

**Dio Cassius**. See DION CASSIUS.

**Dio'cesan** is a bishop viewed in relation to his own clergy or flock.

**Diocesan Courts.** See CONSISTORY and COMMISSARY.

**Diocese** (Fr., from Gr. *dioklês*, 'administration'), the territory over which a bishop exercises ecclesiastical jurisdiction. The term occurs as early as the time of Demosthenes, to signify the treasury or department of finance. It is found in Cicero, both as a Greek and as a Latin word, as the special designation of districts in Asia Minor. At this time, the area denoted by this term was but a small one, for Cicero mentions that three dioceses were included in the single province of Cilicia. But in the organisation of the Roman empire introduced by Constantine the Great, the designation diocese was applied to the larger divisions, which were subdivided into provinces or eparchies. About the middle of the 5th century, the dioceses of the empire were—the East, Asia, Pontus, Thrace, Macedonia, Dacia, Illyria, Italy, Africa, Gaul, Spain, and Britain. The city of Rome, with its seven 'suburbicarian' provinces, constituted a diocese in itself, and was not included in that of Italy. The dioceses were governed collectively by four Prætorian Prefects, each of whom had several such territories under his jurisdiction, and singly by officers styled Eparchs, Counts, or Vicars. The provinces (numbering one hundred and seventeen) were under Exarchs or Rectors. The government of the Christian church, as established by Constantine, was assimilated to this division, and the term diocese and others passed over to ecclesiastical matters. At first a diocese meant an aggregate of metropolitan churches or provinces, each under the charge of an archbishop, which had previously been called a parish, into a single jurisdiction under an exarch (Balsamon, *ad Can. ix., Conc. Chalced.*); and the actual distribution in the 4th and 5th centuries was founded on, and closely corresponded to, the civil division. The four (later five) patriarchates corresponded to the four prætorian prefectures; and the diocese of the Orient contained fifteen provinces, all under the Patriarch of Antioch, till the erection of the patriarchate of Jerusalem in 450, when Palestine, Phœnicia, and Arabia were withdrawn from Antioch to constitute the new jurisdiction; Egypt, under the Patriarch of Alexandria, had six provinces; Asia, eleven; Pontus, eleven; Thrace, six; Macedonia, six; Dacia, five; Italy, seventeen, of which seven were in the diocese of Rome; Illyria, six; Africa, six; Spain, seven; Gaul, seventeen; and Britain, five. In a later stage of the church's history, the term diocese is applied to a single metropolitanate or province (Greg. *Mag. Epist.*, VII. ii. 17), and lastly it came to signify the local jurisdiction of any one bishop (a meaning already applied to it as early as the second Council of Carthage, in 390 A.D., canon v.), of whatever rank. It does not appear in England till the writings of Matthew Paris in the middle of the 13th century; Bede, for example, using only the terms *episcopatus*, *provincia*, *ecclesia*. On the other hand, it is found as the equivalent of 'parish' in canons of the councils of Agde (506 A.D.), Epaon (517), Orleans IV. (541), and also in the capitularies of Charlemagne, VII. c. 360. England is divided ecclesiastically into two provinces—viz. Canterbury and York, the former being presided over by the Primate of All England, and the latter by the Primate of England. Each of them is subdivided into dioceses, and these again into archdeaconries, rural deaneries, and parishes. See BISHOP.

**Diocletian.** VALERIUS DIOCLETIANUS, Roman emperor (284-305 A.D.), was born of humble parentage near Salona, in Dalmatia, in 245. He inherited from his mother, Dioclea, the name

of Diocles, which he afterwards enlarged into Diocletianus, and attached as a cognomen to Valerius, a name of the most patrician associations. He adopted a military career, and served with distinction under Probus and Aurelian, accompanied Carus on his Persian campaign, and finally, on the murder of Numerianus having been discovered at Chalcedon, he was proclaimed emperor in 284 by the army on its homeward march. The suspected assassin of Numerianus, the prefect Arrius Aper, he slew with his own hands, in order, it is alleged, to fulfil a prophecy communicated to him, while still a lad, by a Druidess of Gaul, that he should mount a throne as soon as he had slain the wild-boar (*aper*). Next year he commenced hostilities against Carinus, the joint-emperor along with the deceased Numerianus, who, although victorious in the decisive battle that ensued, was murdered by his own officers, thus leaving to Diocletian the undisputed supremacy. His first years of government were so molested by the incursions of barbarians, that, in order to repel their growing aggressiveness, he took to himself a colleague—namely, Maximian—who, under the title of Augustus, became joint-emperor in 286. Diocletian reserved for himself the charge of the eastern empire, and gave the western to Maximian. Still the attacks of the barbarians continued as formidable as ever. The empire was menaced by the Persians in the east, by the Germans and other barbarians in the west; and in order to provide for its permanent security, Diocletian subjected it to a still further division. In 292 Constantinus Chlorus and Galerius were proclaimed as Cæsars, and the distribution of the Roman empire was now fourfold: Diocletian taking the East, with Nicomedia as his seat of government; Maximian, Italy and Africa, with Milan as his residence; Constantius, Britain, Gaul, and Spain, with Trèves as his headquarters; Galerius, Illyricum and the entire valley of the Danube, with Sirmium as his imperial abode. It was upon his colleagues that most of the burden of engaging actively in hostilities fell, as Diocletian seldom took the field in person. Among the conquests, or rather re-conquests, that were made under his rule, may be enumerated that of Britain, which, after maintaining independence under Carausius and Allectus, was in 296 restored to the empire; that of the Persians, who were defeated, and compelled to capitulate in 298; and that of the Marcomanni, and others of the northern barbarians, who were driven beyond the Roman frontier. Diocletian, after twenty-one years' harassing tenure of government, desired to pass the remainder of his days in tranquillity. Accordingly, on the 1st of May 305, he abdicated the imperial throne at Nicomedia, and compelled his reluctant colleague, Maximian, to do likewise at Milan. He sought retirement in his native province of Dalmatia, and for eight years resided at Salona, devoting himself to philosophic reflection, to rural recreation, and to horticultural pursuits. Two years before his abdication, he was instigated by his colleague, Galerius, to that determined and sanguinary persecution of the Christians for which his reign is chiefly memorable. He died in 313.

**Dio'dati, JEAN**, a Calvinistic divine, was born at Geneva, 6th June 1576, became professor of Hebrew there in 1597, pastor of the reformed church in 1608, and in 1609, on the death of Beza, professor of Theology. He was a preacher at Nîmes from 1614 to 1617, and at the Synod of Dort was representative of Geneva. Diodati, whose family was originally of Lucca in Italy, tried in vain to introduce the reformed doctrine in Venice. He is remembered chiefly through his Italian translation of the Bible, issued (without imprint) at

Geneva in 1607, which was one of the best translations of the Reformation period, and is still in use. His *Annotaciones in Biblia* (1607) are also of value. He died at Geneva, 3d October 1649. See Budé, *Vie de Jean Diodati* (Geneva, 1869).—A nephew, CHARLES DIODATI (*circa* 1608–38), is remembered as the friend of Milton. Son of a doctor who had settled in England, he was educated at St Paul's School, and Trinity College, Oxford, and for the last nine years of his life practised medicine near Chester and in Blackfriars.

**Diodon.** See GLOBE-FISH.

**Diodorus Siculus**, a Greek historian, was born at Agrigum, in Sicily. Little is known of his life beyond what is told by himself. He lived in the times of Julius Cæsar and Augustus, travelled in Asia and Europe, and lived a long time in Rome, collecting the materials of his great work, the compilation of which occupied thirty years. This work, the *Bibliothêkê Historikê*, was a history of the world, in forty books, from the creation to the Gallic wars of Julius Cæsar. It was divided by the author into three parts—the first of which, in six books, comprises all the Greek and foreign mythical history down to the Trojan war; the second, in eleven books, contains the history from the year 1184 B.C. to the death of Alexander the Great; the third, in twenty-three books, continues the narrative of events from that date to the year 60 B.C. Of this great work, the first five books are extant entire; the next five books are wholly lost; the next ten are complete; and of the remainder of the work, considerable fragments have been preserved in the *Excerpta* in Photius, and in the *Eclogæ* prepared by command of Constantine Porphyrogenitus. Had Diodorus Siculus possessed any powers either of criticism or of arrangement, his work would have been of the greatest importance; but he was in both respects so deficient, that his history has no practical value beyond what belongs to an immense mass of raw and now scarcely available material. His narrative is colourless and monotonous, and his diction, generally clear and simple, holds a sort of middle place between the pure Attic and the colloquial Greek of his time. The best editions of Diodorus Siculus are Wesseling's (Amst. 1746) and L. Dindorf's (1828–31); re edited by Vogel (1888–93) and by Fischer (1905–6).

**Diœcious** (Gr. *dis*, 'twice'; and *oikos*, 'a habitation'), a term applied by Linnaeus to plants in which separate individuals exclusively produce male and female flowers respectively. Great importance was attached to this in the artificial system of classification; but diœcious species occur in all groups of plants indifferently, however commonly hermaphrodite; and similarly, hermaphrodite forms occur in groups usually diœcious. This is probably explained by regarding the complete separation of the sexes as a phase of evolution beyond hermaphroditism which tends to arise in plants as in animals, and from which reversion to hermaphroditism may also readily occur, probably in conditions favourable to vegetativeness, (see SEX, REPRODUCTION). Familiar examples of diœcious plants may be seen in most species of willow, or in the pink or white *Lychnis* (*L. diurna* and *L. vespertina*), or the Common Nettle (*Urtica dioica*). Amongst cultivated plants, hemp, spinach, and the date-palm may be instanced.

**Diogenes**, the Cynic philosopher, was a native of Sinope, in Pontus, where he was born about 412 B.C. His father, a banker named Icesias or Icetas, was convicted of swindling, and so the young Diogenes had to leave Sinope and go to Athens. His youth had been that of a spendthrift and a rake, but at Athens his interest was arrested by the character of Antisthenes, who, however, re-

pelled his first advances. But not even blows could restrain the enthusiastic ardour of the young disciple, and at length Antisthenes, moved with compassion, consented to admit him as a pupil. From an extravagant debauchee, Diogenes at once became an ascetic of the extremest austerity. He would roll in hot sand during the heat of summer; in winter, he would embrace a statue covered with snow. His clothing was of the coarsest, his food of the plainest. His bed was the bare ground, in the open street or under the porticoes. At length he is said to have found himself a permanent residence in a tub which belonged to the Metroum, or the temple of the Mother of the Gods. His eccentric life did not cost him the respect of the Athenians, who admired his contempt for comfort, and allowed him a wide latitude of comment and rebuke. Practical good was the chief aim of his philosophy; for literature and the fine arts he did not conceal his disdain. He laughed at men of letters for reading the sufferings of Ulysses, while neglecting their own; at musicians who spent in stringing their lyres the time which would have been much better employed in making their own discordant natures harmonious; at philosophers for gazing at the heavenly bodies, while sublimely incognisant of earthly ones; at orators who studied how to enforce truth, but not how to practise it. He was seized by pirates on a voyage to Ægina, and carried to Crete, where he was sold as a slave. When asked what business he understood, he answered: 'How to command men.' His purchaser was Xenias of Corinth; but the slave soon came to rule the master, acquired his freedom, was appointed tutor to the children, and spent his old age as one of the household. Here perhaps he had his interview with Alexander the Great. The king opened the conversation with: 'I am Alexander the Great,' to which the philosopher answered: 'And I am Diogenes the Cynic.' Alexander then asked him in what way he could serve him, to which Diogenes rejoined: 'You can stand out of the sunshine.' Alexander is said to have been so struck with the Cynic's self-possession, that he went away remarking: 'If I were not Alexander, I would be Diogenes.' The philosopher lived at Corinth till his death at the age of ninety, 323 B.C. See Hermann's *Diogenes* (1860); Zeller's *Philosophy of the Greeks* (trans. 1881–97).

**Diogenes Laërtius** seems to have been born at Laerte, in Cilicia, and to have taken his surname from that town. Little is known of his history; but it is most probable that he flourished in the 2d century A.D. His name has been kept alive by his *Lives of the Philosophers*, a work in ten books, in which he divides the philosophy of the Greeks into the Ionic—beginning with Anaximander, and ending with Chrysippus and Epicurus—and the Italian, founded by Pythagoras, and ending with Epicurus. The Socratic school was a part of the Ionic philosophy; to the Italian belong the Eleatics, with Heraclitus and the Sceptics. This work contains a great mass of interesting information regarding the private lives and habits of the most eminent philosophers of antiquity. Though it is utterly worthless in respect of plan, coherence, or criticism, it yet contains many piquant anecdotes and many valuable quotations from lost works. The standard edition is Cobet's (1850; new ed. 1862).

**Diognetus**, THE EPISTLE TO, an ancient Christian work in Greek, dating from the 2d or 3d century A.D., erroneously ascribed to Justin (q.v.), and usually printed and commented on with the Apostolic Fathers (q.v.). Diognetus may have been the tutor of Marcus Aurelius.

**Diomed Islands**, three small islands (Fairway, Krusenstern, and Ratmanoff) in Behning Strait.

**Diomedes**, the bravest, after Achilles, of all the Greeks who took part in the Trojan war. The son of Tydeus, he is constantly called by his patronymic, Tydides. He vanquished in fight Hector and Æneas, the most valiant of the Trojans; and even Ares and Aphrodite, when they took the field on the Trojan side, were attacked and wounded by him. In the games instituted by Achilles in honour of Patroclus, he gained the prize in the chariot-race, and worsted the mighty Ajax in single combat. Along with Ulysses, he carried off the Palladium, on which the fate of Troy depended. On returning to Argos, to the crown of which he had succeeded after the death of Adrastus, he found that his wife had proved unfaithful in his absence, whereupon he sailed away to Italy, there married the daughter of King Daunus, and lived to a good old age. The towns of Beneventum, Venusia, Canusium, and Brundisium claimed to have been founded by him.

**Dion**, a Syracusan, whose sister became the second wife of the elder Dionysius the Tyrant, while he himself was married to a daughter of Dionysius, his own niece. His close connection with the tyrant brought him great wealth, but his austere manners and devotion to philosophy made him hateful to Dionysius the Younger, who under the guidance of Philistus and his party disregarded the advice of Plato, and banished Dion. Thereupon he retired to Athens to devote himself to the study of philosophy under the guidance of Plato. His expedition to Syracuse resulted in his making himself master of the city (356 B.C.), but his severity made him unpopular among its luxurious citizens, and a plot was formed against him through which he was murdered in his own house three years later. His life was written by both Plutarch and Cornelius Nepos, and he is the subject of a noble poem by Wordsworth.

**Dionaea**, a very curious and interesting genus of Droseraceæ. Only one species is known, *D. muscipula*, sometimes called Venus's Fly-trap and the Carolina Catchfly Plant. It grows in marshy places in Delaware and North Carolina. The remarkable insect-catching and digestive powers exhibited by the leaves are described under INSECTIVOROUS PLANTS.

**Dion Cassius**, surnamed Cocceianus, from the orator Dion Chrysostomus Cocceianus, most likely his maternal grandfather, a celebrated Greek historian, was born at Nicæa, in Bithynia, c. 155 A.D. About 180 he went to Rome, held successively all the high offices of state, was twice consul, and enjoyed the intimate friendship of Alexander Severus, who sent him as legate to Dalmatia and Pannonia. About 229 he retired to his native city, where he passed the remainder of his life. He is best known by his *History of Rome*, from the landing of Æneas in Italy down to 229 A.D., in eighty books, of which but nineteen, from the thirty-sixth to the fifty-fourth, have reached us complete. These embrace the history from the wars of Lucullus and Pompey against Mithridates, down to the death of Agrippa, 10 A.D. The first twenty-four books exist only in the merest fragments; of the last twenty we have only the 11th-century epitome of Xiphilinus. The *Annals* of Zonaras followed Dion Cassius so closely, that we may almost consider that work as an epitome. The position of Dion Cassius gave him free access to the national archives, and his work has considerable value for the imperial epoch of Roman history. His model was Thucydides. See editions by Sturz (1824), Bekker (1849), L. Dindorf (1865; new ed. 1890), and Boissvain (1895-1901); and the 'Loeb Library' edition with Cary's translation (1914 et seq.).

**Dion Chrysostomus** ('the golden-mouthed'),

an eminent Greek rhetorician, surnamed Cocceianus from his intimate friendship with the Emperor Cocceius Nerva, was born at Prusa, in Bithynia, about 50 A.D. His father, Pasirates, paid great attention to his education, which was perfected by travel. He came to Rome under Vespasian, but had afterwards to leave the city, having had the misfortune to excite the suspicion of Domitian. He next visited—in the disguise of a beggar, and on advice of the Delphic oracle—Thrace, Mysia, and Scythia. On the accession of Nerva (96 A.D.) he returned to Rome, and lived in great honour under that ruler and his successor Trajan till his own death, about 117 A.D. As many as eighty of his orations are still extant, with fragments of fifteen others. They are, however, treatises rather than orations proper, discussing questions in politics, morals, and philosophy. These are well reasoned, clear, and eloquent, and are written in pure Attic Greek. Dion Chrysostomus was 'the first writer after Tiberius,' says Niebuhr, 'that greatly contributed towards the revival of Greek literature.' Good editions are by Reiske (1784), Emper (1844), Dindorf (1857), and Von Arnim (1893-95).

**Dionysius of Alexandria**, often surnamed 'the Great,' was the greatest pupil of Origen, succeeded Heraclas as head of the Catechists' school in 232, became Bishop of Alexandria in 247, was banished during the persecutions of Decius (250) and Valerian (257), and died in 264. He distinguished himself by his wisdom and moderation in the great church controversies of his time, on the Novatian schism, on the baptism of heretics, on Chiliasm, and on the heresies of the Sabellians and Paul of Samosata. He was distinguished also as an exegete; the Apocalypse he refused to assign to the Apostle John on grounds which show that he had critical faculty and independence.

Of his numerous writings only a few fragments remain; these were collected by Routh in his *Reliquiæ Sacre* (1814), by Mai in *Auctores Classici* (1838), and by Feltes in *The Letters and Remains of Dionysius of Alexandria* ('Patristic Texts,' 1904-5). See also Feltes's translation (1918), and books on him by Dittrich (German, 1867) and Morize (French, 1881); and works quoted at ORIGEN.

**Dionysius of Halicarnassus**, critic, historian, and rhetorician, lived in the 1st century B.C. He came to Rome about 29 B.C., and lived there on terms of intimacy with many distinguished contemporaries till his death, c. 7 B.C. His most valuable work is unquestionably his Greek *Archæologia*, a history of Rome down to 264 B.C., a mine of information about the constitution, religion, history, laws, and private life of the Romans. Of the twenty books of which it originally consisted, we possess only the first nine in a complete form, the tenth and eleventh nearly so, coming down but to 441 B.C.; of the rest, only a few fragments are extant. He was a greater rhetorician and critic than historian, and his extant works on oratory, on the criticism in detail of the great Greek orators, on the characteristics of poets and historians from the time of Homer to Euripides, and upon Thucydides and Dinarchus, possess great interest and value. See the editions by Jacobi (1835-91) and Usener and Rademacher (1899); and books on him by W. R. Roberts (1901) and Max Egger (Paris, 1902).

**Dionysius**, surnamed THRAX ('the Thracian'), a native of Alexandria, who taught at Rhodes and at Rome about 100 B.C. His *Techne Grammatike* is the foundation of all subsequent European works on grammar. There is an edition by Uhlig (1884).

**Dionysius the Areopagite** (i.e. member of the Areopagus, q.v.), one of the few Athenians who, according to Acts, xvii. 34, were converted by the preaching of the Apostle Paul. Tradition makes him the first Bishop of Athens, and a

martyr of the church. The celebrated Greek writings which bear his name, and, connecting Neoplatonism with Christianity, laid the foundation for the mystical theology of the church, were not written by him, but attributed to him after a fashion not uncommon in antiquity. They are first mentioned in 533, when they were appealed to by the Monophysite sect of the Severians against the authority of the Council of Chalcedon. From the 6th century they were generally accepted as genuine, and exercised a very great influence on the development of theology. They include writings *On the Heavenly Hierarchy*, *On the Ecclesiastical Hierarchy*, *On Divine Names*, *On Mystical Theology*, and a series of ten *Epistles*. In the Western Church they are first referred to in one of the *Homilies* of Gregory the Great. In the 9th century Erigena, at Charles the Bald's command, prepared an annotated Latin translation; and he and many of the scholastic theologians who followed him drew much of their inspiration from this source. The date assigned to the pseudo-Dionysian writings is fixed by Kanakis as early as 120, by Frothingham as late as 520. Harnack holds that it has not yet been decided at what period between 350 and 500 they were written, and adheres provisionally to the second half of the 4th century, with a final recension about the year 500. This great unknown thinker was probably an Alexandrian. His fundamental thought is the absolute transcendence of God, which he attempts to connect with Pantheism by regarding God as absolute causality, and as multiplying himself through his indwelling love in all things. His theology is twofold—on the one hand, descending from God to created things, and concluding from these the absolute inexhaustible being of the One; on the other hand, rising from things to God, denying of him everything that is conceivable, and finding him exalted above truth and error, being and not-being. 'The divine darkness is unapproachable light.' The Incarnation is part of the self-unfolding of God in the world, and the redemption of the individual is mediated by the three degrees of the heavenly hierarchy, and by the three degrees of the church's hierarchy—bishops, priests, and deacons, and the *media* between them are the six 'mysteries', or symbolical priestly actions, to each of which is attributed a special mysterious significance.

The standard edition is that of the Jesuit, Balthasar Corderius (Antwerp, 1634; Brescia, 1854; and reprinted in Migne's collection). German translations by Engelhardt (1823), French by Darboy (1845), and English by Rev. John Parker (1894). See DEMIS (Str); and the studies by Hippler (1861), Niemeyer (1869), and Schneider (1884); Dörner's *Doctrine of the Person of Christ*, div. ii. vol. i.; Harnack's *Dogmengeschichte*, vol. ii.; and Hugo Koch's *Pseudo-Dionysius* (1900).

**Dionysius** the Elder, tyrant of Syracuse, was born about 430 B.C. He was originally a clerk in a public office, but early showed a passion for political and military distinction. When the Agrigentines, after the conquest of their city by the Carthaginians, charged the Syracusan generals with treachery, Dionysius supported their accusations, and induced the Syracusans to appoint new commanders, of whom he himself was one. But in a very short time he supplanted his colleagues also, and so made himself at twenty-five absolute ruler of the city. To strengthen his position he married the daughter of Hermocrates, the late head of the aristocratic party. After suppressing with ferocity several insurrections, and conquering some of the Greek towns of Sicily, he made preparations for a great war with the Carthaginians, which began in 397. At first fortune favoured Dionysius, but after a short time he suffered a series of reverses so calamitous, that all his allies abandoned him, and he was shut up in Syracuse apparently without hope

of escape. When he was about to fall a victim to despair, a pestilence broke out in the Carthaginian fleet. Dionysius took courage, and suddenly attacking his enemies by land and sea, obtained a complete victory. In the years 393 and 392 the Carthaginians renewed hostilities, but were defeated on both occasions, and Dionysius was enabled to conclude a most advantageous peace. He now turned his arms against Lower Italy, and in 387, after a siege of eleven months, captured Rhegium. From this time he continued to exercise the greatest influence over the Greek cities of Lower Italy, while his fleets swept the Tyrrhenian and Adriatic seas. But Dionysius was not contented with the reputation of being the first warrior and statesman of his age; he wished to shine as a poet also. He even ventured so far as to contend for the prize at the Olympic games, but the best reciters of the time, reading his poems with their utmost art, could not induce the judges to decide in his favour. Dionysius was more successful at Athens, where he several times obtained the second and third prizes for tragedy, his last production obtaining the first. He also invited many poets and philosophers to his court, as Philoxenus and Plato, but these distinguished guests were not always safe from his capricious violence. He adorned Syracuse with splendid temples and public buildings. One of his works was the gloomy and terrible rock-hewn dungeon called Lautumia. In 368 he renewed the war with the Carthaginians, whom he wished to drive out of Sicily altogether, but died suddenly next year, not without a suspicion that his physician had hastened nature to make favour with his son. Dionysius was a most vigorous but unscrupulous ruler. His last years were tormented with an excessive dread of treachery.

**Dionysius** the Younger, son of the preceding, succeeded his father in 367 B.C., and celebrated his accession by a splendid festival, which lasted ninety days. His political education had been designedly neglected by his father, and in consequence he grew up an indolent, pleasure-loving, and dissolute prince. Dion (q.v.), who was at once his father's son-in-law and brother-in-law, sought to improve him by the instructions of Plato, but his endeavours were frustrated by Philistus, the historian, who disgracefully encouraged the excesses of the youth. Dion was banished, but afterwards returning to Sicily, expelled Dionysius from Syracuse in 356. The latter fled to Locri, the birthplace of his mother, Doris, where he was hospitably received. He repaid the kindness of the Locrians by making himself master of their city, which he ruled despotically for several years. In 346 the internal dissensions of Syracuse enabled him to return thither, and here he ruled for three years until Timoleon came from Corinth to free Sicily. Dionysius soon had to surrender, and was allowed to spend the rest of his life at Corinth, where he haunted low company, spent his means, and had to keep a school for bread.

**Dionysius Exiguus** (or 'the Little'), so named either from his small stature, or by his own monkish humility, was a Scythian by birth, and became abbot of a monastery at Rome, where he died in 556. He was one of the most learned men of his time, translated various theological writings from Greek into Latin, and is especially noted for his fixing of the Christian era (see CHRONOLOGY), and his collection of canons. See CANON LAW.

**Dionysus.** The worship of Dionysus, who was originally the god of vegetation, and not till after the time of Homer the god of wine, was borrowed by the Greeks from the Thracians. When adopted as a Greek god he was naturally made the son of

Zeus, the sky from which falls the rain that makes the vegetation grow. His mother, Semelē, was destroyed before his birth through her own folly in begging the sky-god to visit her in all his majesty of thunder and lightning. As the remainder of the period of gestation was accomplished in the thigh of Zeus, the paternity of Dionysus was made doubly sure by the myth, and Dionysus was called the 'twice born.' The spread of the worship of the god is mirrored in myths which represent him as bestowing blessings on those who accepted him, and madness on those who, like Lycurgus and Pentheus, resisted him. The peculiar characteristic of the cult is that it is *orgiastic*. Of the orgies as they were actually celebrated we may form an idea from the way in which at the present day in France (on the *jour des brandons*) the peasants carry torches, and utter loud cries, for the purpose of insuring fertility in vineyard and orchard; and in South Germany they dance and leap and make every kind of noise in order to 'rouse the corn,' 'to wake the spring'—the madder the dance and the cries, the more effectual the invocation. In mythology the 'orgies' are imagined as being performed by Mænades, Bacchantes, and others, who in their ecstasies rend animals to pieces, as they rush with their torches by night over the land. Part of the cult of Dionysus consisted in eating oxen and goats, which were regarded as the incarnation of the generative power of which Dionysus was the god. Mythology makes Dionysus himself, under the name of Zagreus, to have been devoured by the Titans; his heart alone was saved, and he was born again as the son of Semelē. The orgiastic worship of Dionysus explains the fact that wine when it became known was regarded as the gift of Dionysus (see BACCHUS).—The *Dionysia* were festivals held in his honour throughout Greece. In Attica alone there were four *Dionysia* at different seasons of the year—the most important, the *Lenæa*, celebrated with a procession and scenic contests in tragedy and comedy, out of which grew all the glories of the Greek drama.

**Dioön.** See CYCADS.

**Diophantus**, one of the last of the great Greek mathematicians, lived at Alexandria, most probably in the second half of the 3d century of our era. He died at the age of eighty-four. The titles

of three of his works are *Arithmetics*, *Polygonal Numbers*, and *Porisms*. Of the first, which consisted of thirteen books, only six remain; of the second we possess merely a fragment; and the third has been entirely lost. The *Arithmetics* is the earliest extant treatise on algebra, but it would be rash to say that Diophantus was the inventor of algebra, though to what extent he was indebted to his predecessors cannot now be decided. The first book of the *Arithmetics* is occupied with problems leading to determinate equations of the first degree, the rest of the books with problems leading to indeterminate equations of the second degree, the sixth book in particular being devoted to the finding of right-angled triangles where some linear or quadratic function of the sides is to be a square or a cube. The treatise on *Polygonal Numbers* is not analytical but synthetical—i.e. in the manner of Euclid's arithmetical books—and in it numbers are represented by lines. The *Porisms* were probably a collection of propositions on the properties of certain numbers. The first translation of Diophantus was into Latin by Xylander (Wilhelm Holzmann) in 1575. The only edition of the Greek text was that by Bachet (published with a Latin translation in 1621, and reprinted with Fermat's notes and many misprints in 1670), until it was critically edited by Tannery (1893-95). See T. L. Heath's *Diophantos of Alexandria* (1885; enlarged ed. 1910).

**DIOPHANTINE ANALYSIS**, so called from Diophantus, is that part of algebra which treats of the finding of particular rational values for general expressions under a surd form. A simple example of a diophantine problem is to find a right-angled triangle whose three sides are expressible by rational numbers, or in other words, to divide a square number into two squares (Diophantus, *Arithmetics*, ii. 9). A diophantine theorem less simple is the statement of Fermat, which even yet has only been partially proved, that the equation  $x^n + y^n = z^n$  is impossible for every integral value of  $n$  greater than 2. The diophantine analysis is really a part of what is now called the theory of numbers, and its development is to be sought in the writings of those mathematicians, from Fermat and Euler downwards, who have cultivated this subject. Much information regarding it will be found in the second part of Euler's *Algebra*.
